MACAO, an island of China, in the province of Canton, fifty miles south of Canton.

MACAO, in ornithology. See **PSITTACUS**.

MACCABEES, two apocryphal books of scripture; so called from Judas Mattathias, surnamed Maccabeus. The first book of the Maccabees is an excellent history, and comes nearest to the style and manner of the sacred historians of any extant. It contains the history of forty years, from the reign of Antiochus Epiphanes to the death of Simon the high priest; that is, from the year of the world 3829 to the year 3869, 131 before Christ. The second book of the Maccabees begins with two epistles sent from the Jews of Jerusalem to the Jews of Egypt and Alexandria, to exhort them to observe the feast of the dedication of the new altar erected by Judas on his purifying the temple. After these epistles follows the preface of the author to his history, which is an abridgment of a larger work, composed by one Jason, a Jew of Cyrene, who wrote the history of Judas Maccabeus and his brethren, and the wars against Antiochus Epiphanes and Eupator his son. This second book does not, by any means, equal the accuracy and excellency of the first. It contains a history of about fifteen years, from the execution of Heliodorus's commission, who was sent by Seleucus to fetch away the treasures of the temple, to the victory obtained by Judas Maccabeus over Nicanor; that is, from the year of the world 3828, to the year 3843, 147 years before Christ.

MACCLESFIELD, a market-town of Cheshire, thirty-five miles east of Chester, from whence the noble family of Parker take the title of earl.

VOL. III. N^o 69.

2

MACE, the second coat or covering of the kernel of the nutmeg, is a thin and membranaceous substance, of an oleaginous nature and a yellowish colour; being met with in flakes of an inch and more in length, which are divided into a multitude of ramifications. It is of an extremely fragrant, aromatic and agreeable flavour, and of a pleasant, but acrid and oleaginous taste.

Mace is carminative, stomachic, and astringent; and possesses all the virtues of nutmeg, but is less astringent.

MACEDONIA, a province of European Turkey, bounded by Servia and Romania, on the north and east; by the gulphs of Salonichi, Contessa and Thessaly, on the south; and by Albania and Epirus, on the west.

MACERATION, is an infusion of, or soaking ingredients in water or any other fluid, in order either to soften them, or draw out their virtues.

MACHIAN, a small island of the Moluccas, which produces the best cloves: it is situated under the equator, in 125° E. long. and is subject to the Dutch.

MACHINE, in general, whatever hath force sufficient to raise or stop the motion of a heavy body. See **MACHANICS**.

MACHINERY, in epic and dramatic poetry, is when the poet introduces the use of machines, or brings some supernatural being upon the stage, in order to solve some difficulty, or to perform some exploit out of the reach of human power. See **COMPOSITION**.

MACKERAN, or **MACKAN**, the capital of a province in Persia of the same name; situated in E. long 66°, and N. lat. 26°.

MACKEREL, in ichthyology. See **SCOMBER**.
↑ A **MACROCERCI**,

MACROCERCI, a name given to that class of animalcules, with tails longer than their bodies.

MACROPYRENIUM, in natural history, a genus of fossils, consisting of cruftated septariæ, with a long nucleus standing out at each end of the mass.

MACROTELOSTYLA, in natural history, a name of a genus of crystals, which are composed of two pyramids, joined to the end of a column; both the pyramids, as also the column, being hexangular, and the whole body consequently composed of eighteen planes.

MACULE, in astronomy, dark spots appearing on the luminous faces of the sun, moon, and even some of the planets. See **ASTRONOMY**.

These spots are most numerous and easily observed in the sun. It is not uncommon to see them in various forms, magnitudes, and numbers, moving over the sun's disk. They were first of all discovered by the lincean astronomer Galileo, in the year 1610, soon after he had finished his new-invented telescope.

MAD APPLE. See **SOLANUM**.

MADAGASCAR, or *St LAURENCE*, an island of Africa, situated between 43° and 51° of east longitude, and between 12° and 26° south latitude; three hundred miles south-east of the continent of Africa. It is about a thousand miles in length from north to south, and generally between two and three hundred miles broad. The country is divided among a great number of petty sovereigns.

MADDER. See **RUBIA**.

MADERAS, some islands situated in the Atlantic ocean, three hundred miles west of Salæe, in Africa; in 16° W. long. and between 32° and 33° of N. lat.

The largest of them, called Madera, or rather Mattered, by the Portuguese, is about an hundred and twenty miles in circumference, and produces incredible quantities of wine, which has the peculiar quality of keeping best in hot climates, where other wines turn sour.

MADNESS, a most dreadful kind of delirium, without a fever. See **MEDICINE**.

MADRAS, a town on the coast of Cormandel, inhabited by blacks, and situated just without the walls of the White town of Fort St George.

MADRE DE POPA, a town and convent of Terra Firma, in South America, situated on the river Grande, fifty miles east of Carthagea, almost as much resorted to by the pilgrims of America, as the chapel of Loreto is by the pilgrims of Europe: W. long. 76° N. lat. 11°.

MADRID, the capital of the province of New Castile, and of the whole kingdom of Spain: W. long. 4° 15', and N. lat. 4° 30'.

MADRIGAL, is a short amorous poem, composed of a number of free and unequal verses, neither confined to the regularity of a sonnet, nor to the point of an epigram, but only consisting of some tender and delicate thought, expressed with a beautiful, noble, and elegant simplicity.

MADRIGAL, in geography, a city of the province of Popayan, in south America: W. long. 75° 30', and N. lat. 30'.

MADURA, the capital of the province of the same name in the hither India: E. long. 77°, and N. lat. 10°.

MÆMACTERION, the fourth month of the Athenian year, consisting of only twenty-nine days, and answering to the latter part of September and the beginning of October.

MÆNA, in ichthyology. See **SPARUS**.

MAES, a river which arises in Burgundy, and runs through Lorrain and Champaign into the Netherlands, and at last, after passing by many considerable towns, discharges itself into the German sea, a little below the Briel.

MAESTRICHT, a town in the province of Brabant, situated on the river Maes, thirteen miles north of Liege: E. long. 5° 40', and N. lat. 50° 55'.

MAGADOXA, the capital of the territory of the same name, at the mouth of the river Magadoxa, on the coast of Anian, in Africa: E. lon. 41°, and N. lat. 2°.

MAGAZINE, a place in which stores are kept, of arms, ammunition, provisions, &c. Every fortified town ought to be furnished with a large magazine, which should contain stores of all kinds, sufficient to enable the garrison and inhabitants to hold out a long siege, and in which smiths, carpenters, wheelwrights, &c. may be employed, in making every thing belonging to the artillery, as carriages, waggon, &c.

MAGDALEN, or *Nuns of St MAGDALEN*, an order of religious in the Romish church, dedicated to St Mary Magdalene, and sometimes called Magdalenettes. These chiefly consist of courtizans, who, quitting their profession, devote the rest of their lives to repentance and mortification.

MAGDEBURG, the capital of the duchy of the same name, situated on the river Elbe, seventy miles west of Berlin: E. long. 12°, and N. lat. 52° 15'.

MAGDELENA, a large river of South America, which, rising near the equator, runs north through Terra Firma, and, uniting its waters with the river Cance, obtains the name of the river Grande, and falls into the north sea, below the town of Madre de Popa.

MAGELLAN STRAIGHTS, or rather *Straights of MAGELLAN*. These Straights are about three hundred miles in length from the Atlantic to the Pacific ocean, but of a very unequal breadth; and were at first discovered and passed by Ferdinand Magellan, from whom they had their name: they are situated between the island Terra del Fuego and the most southern part of the continent of America, between 76° and 84° of W. long. and between 52° and 54° of south lat.

MAGI, or **MAGIANS**, an ancient religious sect in Persia and other eastern countries, who maintained, that there were two principles, the one the cause of all good, the other the cause of all evil; and, abominating the adoration of images, worshipped God only by fire, which they looked upon as the brightest and most glorious symbol of Oromasdes, or the good God; as darkness is the truest symbol of Arimanius, or the evil god. This religion was reformed by Zoroaster, who maintained that there was one supreme independent being; and under him two principles or angels, one the angel

of goodnefs and light, and the other of evil and darknefs : that there is a perpetual struggle between them, which fhall laft to the end of the world ; that then the angel of darknefs and his difciples fhall go into a world of their own, where they fhall be punifhed in everlasting darknefs ; and the angel of light and his difciples fhall alfo go into a world of their own, where they fhall be rewarded in everlasting light.

The priefts of the magi were the moft fkillful mathematicians and philofophers of the ages in which they lived, inasmuch that a learned man and a magian became equivalent terms. The vulgar looked on their knowledge as more than natural, and imagined them infpired by fome fupernatural power ; and hence thofe who praftifed wicked and mifchievous arts, taking upon themfelves the name of magians, drew on it that ill fignification which the word magician now bears among us.

This feft ftill fubfifts in Perfia, under the denomination of gours, where they watch the facred fire with the greateft care, and never fuffer it to be extinguifhed.

MAGIC, originally fignified only the knowledge of the more fublime parts of philofophy ; but as the magi likewife profefled astrology, divination and forcery, the term magi became odious, being ufed to fignify an unlawful difobedient kind of fcience, acquired by the affiftance of the devil and departed fouls.

MAGIC LANTERN, in optics. See **OPTICS**.

MAGISTRY, in chemiftry, a very fine powder made by folution and precipitation.

MAGISTRY of Bifmuth. See **CHEMISTRY**, p. 90.

MAGISTRATE, any public officer to whom the executive power of the law is committed, either wholly or in part.

MAGNA ASSISA ELIGENDA, is a writ anciently directed to the fheriff for fummoning four lawful knights before the juftices of affize, in order to chufe twelve knights of the neighbourhood, &c. to pafs upon the great affize between fuch a perfon plaintiff, and fuch a one defendant.

MAGNA CHARTA, the great charter of the liberties of Britain, and the bafis of our laws and privileges.

This charter may be faid to derive its origin from king Edward the Confeflor, who granted feveral privileges to the church and ftate by charter : thefe liberties and privileges were alfo granted and confirmed by king Henry I. by a celebrated great charter now loft ; but which was confirmed or re-enacted by king Henry II. and king John. Henry III. the fucceffor of this laft prince, after having caufed twelve men to make inquiry into the liberties of England in the reign of Henry I. granted a new charter, which was the fame as the prefent magna charta : this he feveral times confirmed, and as often broke ; till, in thirty-feventh year of his reign, he went to Weftminfter-hall, and there, in the prefence of the nobility and bifhops, who held lighted candles in their hands, magna charta was read, the king all the while holding his hand to his breaft, and at laft folemnly fwearing faithfully and inviolably to obferve all the things therein contained,

&c. then the bifhops extinguifhing the candles, and throwing them on the ground, they all cried out, " Thus let him be extinguifhed, and ftink in hell, who violates this charter." It is obferved, that notwithstanding the folemnity of this confirmation, king Henry, the very next year, again invaded the rights of his people, till the barons entered into a war againft him, when, after various fuccelfes, he confirmed this charter, and the charter of the foreft, in the fifty fecond year of his reign. This excellent charter, fo equitable and beneficial to the fubject, is the ancienteft written law in the kingdom : by the 25 Edw. I. it is ordained that it fhall be taken as the common law ; and by the 43 Edward III. all ftatutes made againft it are declared to be void.

MAGNESIA. See **CHEMISTRY**, p. 119.

MAGNET, or **LOADSTONE**, in natural hiftory, a very rich iron ore, found in large detached mafles, of a dusky iron-grey, often tinged with brownifh or reddifh, and when broken appearing fomething like the common emery, but lefs fparkling. It is very heavy, confiderably hard, of a perfectly irregular and uneven furface, and of a firm ftructure, but ufually with fome porous irregularities within. It is found in Britain, and all other places where there are iron mines. See **MECHANICS**.

MAGNIFYING, the making of objects appear larger than they would otherwife do ; whence convex lenfes, which have the power of doing this, are called magnifying glaffes. See **OPTICS**.

MAGNITUDE, whatever is made up of parts locally extended, or that hath feveral dimenfions ; as a line, furface, folid, &c.

MAGNOLIA, in botany, a genus of the polyandria polygynia clafs. The calix confifts of three leaves, and the corolla of nine petals ; the capfules are imbricated, and have two valves ; and the feed is a pendulous berry. There are four fpecies, all natives of America.

MAGPY, in ornithology. See **COEURUS**.

MAHOMETANS, thofe who believe in the religion and divine miffion of Mahomet, or Mohammed.

It will not be improper here to give a general account of this extraordinary perfon, and the religion which he had the addrefs to propagate over moft of the eastern nations.

Mohammed was born in the reign of Anufhirwan the Juft, emperor of Perfia, about the end of the 6th century of the Chriftian æra. He came into the world under fome difadvantages. His father Abd'allah was a younger fon of Abd'almotalleb, and, dying very young, and in his father's life time, left his widow and infant fon in very mean circumftances, his whole fubftance confifting but of five camels and one Ethiopian fhe-flave. Abd'almotalleb was therefore obliged to take care of his grandchild Mohammed, which he not only did during his life, but at his death enjoined his eldeft fon Abu Taleb, who was brother to Abd'allah by the fame mother, to provide for him for the future ; which he very affectionately did, and inftructed him in the bufinefs of a merchant which he followed ; and to that end he took him into Syria when he was but thirteen,

and

and afterwards recommended him to Khadijah, a noble and rich widow, for her factor; in whose service he behaved himself so well, that by making him her husband she soon raised him to an equality with the richest in Mecca.

After he began by this advantageous match to live at his ease, it was that he formed the scheme of establishing a new religion, or, as he expressed it, of replanting the only true and ancient one, professed by Adam, Noah, Abraham, Moses, Jesus, and all the prophets, by destroying the gross idolatry into which the generality of his countrymen had fallen, and weeding out the corruptions and superstitions which the latter Jews and Christians had, as he thought, introduced into their religion, and reducing it to its original purity, which consisted chiefly in the worship of one only God.

Before he made any attempt abroad, he rightly judged that it was necessary for him to begin with the conversion of his own household. Having therefore retired with his family, as he had done several times before, to a cave in mount *Hara*, he there opened the secret of his mission to his wife Khadijah; and acquainted her that the angel Gabriel had just before appeared to him, and told him that he was appointed the apostle of God: he also repeated to her a passage which he pretended had been revealed to him by the ministry of the angel, with those other circumstances of this first appearance, which are related by the Mohammedan writers. Khadijah received the news with great joy; swearing by him in whose hands her soul was, that the trusted he would be the prophet of his nation; and immediately communicated what she had heard to her cousin Warakah Ebn Nawfal, who, being a Christian, could write in the Hebrew character, and was tolerably well versed in the scriptures; and he as readily came into her opinion, assuring her that the same angel who had formerly appeared unto Moses was now sent to Mohammed. The first overture the prophet made in the month of Ramadan, in the fortieth year of his age, which is therefore usually called the year of his mission.

Encouraged by so good a beginning, he resolved to proceed, and try for some time what he could do by private persuasion, not daring to hazard the whole affair by expelling it too suddenly to the public. He soon made profelytes of those under his own roof, viz. his wife Khadijah, his servant Zeid Ebn Haretha (to whom he gave his freedom at that occasion, which afterwards became a rule to his followers) and his cousin and pupil Ali, the son of Abu Taleb, though then very young: but this last, making no account of the other two, used to style himself *the first of believers*. The next person Mohammed applied to was Abd'allah Ebn Abi Kohafa, surnamed Abu Beer, a man of great authority among the Koreish, and one whose interest he well knew would be of great service to him; as it soon appeared: for Abu Beer, being gained over, prevailed also on Othman Ebn Affan, Abd'alah Ebn Awf, Saad Ebn Abi Wakkas, al Zobeir Ebn al Awam, and Telha Ebn Obaid'allah, all principal men of Mecca, to follow his example. These men were the six chief companions, who, with a few more, were converted in the space of three years; at the end of which, Mohammed having, as he hoped, a sufficient in-

terest to support him, made his mission no longer a secret, but gave out that God had commanded him to admonish his near relations, and, in order to do it with more convenience and prospect of success, he directed Ali to prepare an entertainment, and invite the sons and descendants of Abd'almoalleb, intending then to open his mind to them: this was done, and about forty of them came; but Abu Laheb, one of his uncles, making the company break up before Mohammed had an opportunity of speaking, obliged him to give them a second invitation the next day; and when they were come, he made them the following speech: "I know no man in all Arabia who can offer his kindred a more excellent thing than I now do you: I offer you happiness both in this life, and in that which is to come; God Almighty hath commanded me to call you unto him; Who therefore among you will be assiduous to me herein, and become my brother and my vicegerent?" All of them hesitating, and declining the matter, Ali at length rose up, and declared that he would be his assiduous; and vehemently threatened those who should oppose him. Mohammed upon this embraced Ali with great demonstrations of affection, and desired all who were present to hearken to and obey him, as his deputy; at which the company broke out into a great laughter, telling Abu Taleb that he must now pay obedience to his son.

This repulse however was so far from discouraging Mohammed, that he began to preach in public to the people, who heard him with some patience. till he came to upbraid them with the idolatry, obsequy and perverseness of themselves and their fathers; which so highly provoked them, that they declared themselves his enemies, and would soon have procured his ruin, had he not been protected by Abu Taleb. The chief of the Koreish warmly solicited this person to desert his nephew, making frequent remonstrances against the innovations he was attempting; which proving ineffectual, they at length threatened him with an open rupture, if he did not prevail on Mohammed to desist. At this Abu Taleb was so far moved, that he earnestly dissuaded his nephew from pursuing the affair any farther, representing the great danger he and his friends must otherwise run. But Mohammed was not to be intimidated, telling his uncle plainly, *that if they set the sun against him on his right hand, and the moon on his left, he would not leave his enterprise*: and Abu Taleb, seeing him so firmly resolved to proceed, used no further arguments, but promised to stand by him against all his enemies.

The Koreish, finding they could prevail neither by fair words nor menaces, tried what they could do by force and ill treatment; using Mohammed's followers so very injuriously, that it was not safe for them to continue at Mecca any longer; whereupon Mohammed gave leave to such of them as had not friends to protect them to seek for refuge elsewhere. And accordingly, in the fifth year of the prophet's mission, sixteen of them, four of whom were women, fled into Ethiopia; and among them Othman Ebn Affan and his wife Rakhiah, Mohammed's daughter. This was the first flight; but afterwards several others followed them, retiring one after another, to the number of eighty-three men and eighteen women, besides

besides children. These refugees were kindly received by the Najahî, or king of Ethiopia, who refused to deliver them up to those whom the Koreish sent to demand them, and, as the Arab writers unanimously attest, even professed the Mohammedan religion.

In the sixth year of his mission Mohammed had the pleasure of seeing his party strengthened by the conversion of his uncle Hamza, a man of great valour and merit, and of Omar Ebn al Khattab, a person highly esteemed, and once a violent opposer of the prophet. As persecution generally advances rather than obstructs the spreading of a religion, Islamism made so great a progress among the Arab tribes, that the Koreish, to suppress it effectually, if possible, in the seventh year of Mohammed's mission, made a solemn league or covenant against the Hashemites and the family of Abd'almoallem, engaging themselves to contract no marriages with any of them, and to have no communication with them; and, to give it the greater sanction, reduced it into writing, and laid it up in the Caaba. Upon this the tribe became divided into two factions; and the family of Hashem all repaired to Abu Taleb, as their head; except only Abd'al Uzza, surnamed Abu Laheb, who, out of his inveterate hatred to his nephew and his doctrine, went over to the opposite party, whose chief was Abu Sofian Ebn Harb, of the family of Ommeya.

The families continued thus at variance for three years; but, in the tenth year of his mission, Mohammed told his uncle Abu Taleb, that God had manifestly shewed his disapprobation of the league which the Koreish had made against them, by sending a worm to eat out every word of the instrument, except the name of God. Of this accident Mohammed had probably some private notice; for Abu Taleb went immediately to the Koreish and acquainted them with it; offering, if it proved false, to deliver his nephew up to them; but, in case it were true, he insisted that they ought to lay aside their animosity, and annul the league they had made against the Hashemites. To this they acquiesced, and, going to inspect the writing, to their great astonishment found it to be as Abu Taleb had said; and the league was thereupon declared void.

In the same year Abu Taleb died, at the age of above fourscore; and it is the general opinion that he died an infidel; though others say, that when he was at the point of death he embraced Mohammedism, and produce some passages out of his poetical compositions to confirm their assertion. About a month, or, as some write, three days after the death of this great benefactor and patron, Mohammed had the additional mortification to lose his wife Khadijah, who had so generously made his fortune. For which reason this year is called the *year of mourning*.

On the death of these two persons the Koreish began to be more troublesome than ever to their prophet, and especially some who had formerly been his intimate friends; inasmuch that he found himself obliged to seek for shelter elsewhere, and first pitched upon Tayef, about sixty miles east from Mecca, for the place for his retreat. Thither therefore he went, accompanied by his servant Zied, and applied himself to two of the chief of the tribe of Thakif who were the inhabitants of that place; but

they received them very coldly. However, he said there a month; and some of the more confederate and better sort of men treated him with a little respect; but the slaves and inferior people at length rose against him, and, bringing him to the wall of the city, obliged him to depart, and return to Mecca; where he put himself under the protection of al Motaam Ebn Adi.

This repulse greatly discouraged his followers: however, Mohammed was not wanting to himself, but boldly continued to preach to the public assemblies at the pilgrimage, and gained several proselytes, and among them six of the inhabitants of Yathreb of the Jewish tribe of Khazraj, who, on their return home, failed not to speak much in commendation of their new religion, and exhorted their fellow-citizens to embrace the same.

In the twelfth year of his mission it was that Mohammed gave out that he had made his night journey from Mecca to Jerusalem, and thence to heaven, so much spoken of by all that write of him. Dr Prideaux thinks he invented it, either to answer the expectations of those who demanded some miracle as a proof of his mission; or else, by pretending to have conversed with God, to establish the authority of whatever he should think fit to leave behind by way of oral tradition, and make his sayings to serve the same purpose as the oral law of the Jews. But it does not appear that Mohammed himself ever expected so great a regard should be paid to his sayings, as his followers have since done; and seeing he all along disclaimed any power of performing miracles, it seems rather to have been a fetch of policy to raise his reputation, by pretending to have actually conversed with God in heaven, as Moses had heretofore done in the mount, and to have received several institutions immediately from him, whereas before he contented himself with persuading them that he had all by the ministry of Gabriel.

However, this story seemed so absurd and incredible, that several of his followers left him upon it; and had probably ruined the whole design, had not Abu Becr vouched for his veracity, and declared that, if Mohammed affirmed it to be true, he verily believed the whole. Which happy incident not only retrieved the prophet's credit, but increased it to such a degree, that he was secure of being able to make his disciples swallow whatever he pleased to impose on them for the future. And this fiction, notwithstanding its extravagance, was one of the most artful contrivances Mohammed ever put in practice, and what chiefly contributed to the raising of his reputation to that great height to which it afterwards arrived.

In this year, called by the Mohammedans the *accepted year*, twelve men of Yathreb or Medina, of whom ten were of the tribe of Khazraj, and the other two of that of Aws, came to Mecca, and took an oath of fidelity to Mohammed at al Akaba, a hill on the north of that city. This oath was called the *women's oath*; not that any women were present at this time, but because a man was not thereby obliged to take up arms in defence of Mohammed or his religion; it being the same oath that was afterwards exacted of the women, the form of which we have in the Koran, and is to this effect; viz. That they should renounce all idolatry; and they should not steal, nor commit fornication, nor kill their children (as the

Pagan Arabs used to do when they apprehended they should not be able to maintain them,) nor forge calumnies; and that they should obey the prophet in all things that were reasonable. When they had solemnly engaged to all this, Mohammed sent one of his disciples, named Mafab Ebn Omair, home with them, to instruct them more fully in the grounds and ceremonies of his new religion.

Mafab being arrived at Medina, by the assistance of those who had been formerly converted, gained several proselytes, particularly Ofaid Ebn Hodeira, a chief man of the city, and Saad Ebn Moadh, prince of the tribe of Aws; Mohammedism spreading so fast, that there was scarce a house wherein there were not some who had embraced it.

The next year, being the thirteenth of Mohammed's mission, Mafab returned to Mecca, accompanied by seventy-three men and two women of Medina who had professed Islamism, besides some others who were as yet unbelievers. On their arrival, they immediately sent to Mohammed, and offered him their assistance, of which he was now in great need; for his adversaries were by this time grown so powerful in Mecca, that he could not stay there much longer without imminent danger. Wherefore he accepted their proposal, and met them one night, by appointment, at al Akaba above-mentioned, attended by his uncle al Abbas, who, though he was not then a believer, wished his nephew well, and made a speech to those of Medina, wherein he told them, that as Mohammed was obliged to quit his native city, and seek an asylum elsewhere, and they had offered him their protection, they would do well not to deceive him; that if they were not firmly resolved to defend, and not betray him, they had better declare their minds, and let him provide for his safety in some other manner. Upon their protesting their sincerity, Mohammed swore to be faithful to them, on condition that they should protect him against all insults, as heartily as they would their own wives and families. They then asked him what recompence they were to expect if they should happen to be killed in his quarrel; he answered, paradise. Whereupon they pledged their faith to him, and so returned home; after Mohammed had chosen twelve out of their number, who were to have the same authority among them as the twelve apostles of Christ had among his disciples.

Hitherto Mohammed had propagated his religion by fair means, so that the whole success of his enterprise, before his flight to Medina, must be attributed to persuasion only, and not to compulsion. For before this second oath of fealty or inauguration at al Akaba, he had no permission to use any force at all; and in several places of the Koran, which he pretended were revealed during his stay at Mecca, he declares his business was only to preach and admonish; that he had no authority to compel any person to embrace his religion; and that, whether people believe or not, was none of his concern, but belonged solely unto God. And he was so far from allowing his followers to use force, that he exhorted them to bear patiently those injuries which were offered them on account of their faith; and, when persecuted himself, chose rather to quit the place of his birth and retire to

Medina, than to make any resistance. But this great passiveness and moderation seem entirely owing to his want of power, and the great superiority of his opposers for the first twelve years of his mission; for no sooner was he enabled, by the assistance of those of Medina, to make head against his enemies, than he gave out, that God had allowed him and his followers to defend themselves against the infidels; and at length, as his forces increased, he pretended to have the divine leave even to attack them; and to destroy idolatry, and set up the true faith by the sword; finding, by experience, that his designs would otherwise proceed very slowly, if they were not utterly overthrown; and knowing, on the other hand, that innovators, when they depend solely on their own strength, and can compel, seldom run any risk; from whence, says Machiavel, it follows, that all the armed prophets have succeeded, and the unarmed ones have failed. Moses, Cyrus, Theus, and Romulus, would not have been able to establish the observance of their institutions for any length of time, had they not been armed. The first passage of the Koran which gave Mohammed the permission of defending himself by arms, is said to have been that in the twenty-second chapter; after which a great number to the same purpose were revealed.

That Mohammed had a right to take up arms for his own defence against his unjust persecutors, may, perhaps, be allowed; but whether he ought afterwards to have made use of that means for the establishing of his religion, is not so easy to determine. How far the secular power may or ought to interpose in affairs of this nature, mankind are not agreed. The method of converting by the sword gives no very favourable idea of the faith which is so propagated, and is disallowed by every body in those of another religion, though the same persons are willing to admit of it for the advancement of their own; supposing that, though a false religion ought not to be established by authority, yet a true one may; and accordingly force is almost as constantly employed in these cases by those who have the power in their hands, as it is constantly complained of by those who suffer the violence. It is certainly one of the most convincing proofs that Mohammedism was no other than a human invention, that it owed its progress and establishment almost entirely to the sword; and it is one of the strongest demonstrations of the divine original of Christianity, that it prevailed against all the force and powers of the world by the mere dint of its own truth, after having stood the assaults of all manner of persecutions, as well as other oppositions, for three hundred years together, and at length made the Roman emperors themselves submit thereto; after which time, indeed, this proof seems to fail, Christianity being then established, and Paganism abolished, by public authority, which has had great influence in the propagation of the one and destruction of the other ever since. But to return:

Mohammed, having provided for the security of his companions as well as his own, by the league offensive and defensive which he had now concluded with those of Medina, directed them to repair thither, which they accordingly did; but himself with Abu Beer and Ali staid behind, having not yet received the divine permission, as

he pretended, to leave Mecca, The Koreish, fearing the consequence of this new alliance, began to think it absolutely necessary to prevent Mohammed's escape to Medina; and having held a council thereon, after several milder expedients had been rejected, they came to a resolution that he should be killed; and agreed that a man should be chosen out of every tribe for the execution of this design; and that each man should have a blow at him with his sword, that the guilt of his blood might fall equally on all the tribes, to whose united power the Hashimites were much inferior, and therefore durst not attempt to revenge their kinsman's death.

This conspiracy was scarce formed, when, by some means or other, it came to Mohammed's knowledge; and he gave out that it was revealed to him by the angel Gabriel, who had now ordered him to retire to Medina. Whereupon, to amuse his enemies, he directed Ali to lie down in his place, and wrap himself up in his green cloak, which he did; and Mohammed escaped miraculously, as they pretend, to Abu Becr's house, unperceived by the conspirators, who had already assembled at the prophet's door. They, in the mean time, looking through the crevice, and seeing Ali, whom they took to be Mohammed himself, asleep, continued watching there till morning, when Ali awoke, and they found themselves deceived.

From Abu Becr's house Mohammed and he went to a cave in mount Thur, to the south-east of Mecca, accompanied only by Amer Ebn Fohairah, Abu Becr's servant, and Abd'allah Ebn Oreitah, an idolater whom they had hired for a guide. In this cave they lay hid three days: to avoid the search of their enemies; which they very narrowly escaped, and not without the assistance of more miracles than one: for some say that the Koreish were struck with blindness, so that they could not find the cave; others, that after Mohammed and his companions were got in, two pigeons laid their eggs at the entrance, and a spider covered the mouth of the cave with her web, which made them look no farther. Abu Becr, seeing the prophet in such imminent danger, became very sorrowful; whereupon Mohammed comforted him with these words, recorded in the Koran, *Be not grieved, for God is with us*. Their enemies being retired, they left the cave, and set out for Medina, by a by road; and having fortunately, or, as the Mohammedans tell us, miraculously escaped some who were sent to pursue them, arrived safely at that city; whither Ali followed them in three days, after he had settled some affairs at Mecca.

The first thing Mohammed did after his arrival at Medina, was to build a temple for his religious worship, and a house for himself, which he did on a parcel of ground which had before served to put camels in, or, as others tell us, for a burying-ground, and belonged to Sahal and Soheil the sons of Amru who were orphans. This action Dr Prideaux exclaims against, representing it as a flagrant instance of injustice; for that, says he, he violently dispossessed these poor orphans, the sons of an inferior artificer (whom the author he quotes calls a carpenter) of this ground, and so founded the first fabric of his worship with the like wickedness as he did his religion. But, to say nothing of the imp obliquity that Mohammed should act in so impolitic a manner at his first coming, the Moham-

medan writers set this affair in a quite different light: one tells us that he treated with the laics about the price of the ground, but they desired he would accept it as a present: however, as historians of good credit assure us, he actually bought it; and the money was paid by Abu Becr. Besides, had Mohammed accepted it as a present, the orphans were in circumstances sufficient to have afforded it; for they were of a very good family, of the tribe of Najjar, one of the most illustrious among the Arabs, and not the sons of a carpenter, as Dr Prideaux's author writes, who took the word Najjar, which signifies a carpenter, for an appellative, whereas it is a proper name.

Mohammed, being securely settled at Medina, and able not only to defend himself against the insults of his enemies, but to attack them, began to send out small parties to make reprisals on the Koreish; the first party consisting of no more than nine men, who intercepted and plundered a caravan belonging to that tribe; and in the action took two prisoners. But what established his affairs very much, and was the foundation on which he built all his succeeding greatness, was the gaining of the battle of Bedr, which was fought in the second year of the Hejra, and is so famous in the Mohammedan history. Some reckon no less than twenty-seven expeditions wherein Mohammed was personally present, in nine of which he gave battle, besides several other expeditions in which he was not present. His forces he maintained partly by the contributions of his followers for this purpose, which he called by the name of *zacam* or alms, and the paying of which he very artfully made one main article of his religion; and partly by ordering a fifth part of the plunder to be brought into the public treasury for that purpose, in which matter he likewise pretended to act by the divine direction.

In a few years, by the success of his arms (notwithstanding he sometimes came off by the worst) he considerably raised his credit and power. In the sixth year of the Hejra he set out with 1400 men to visit the temple of Mecca, not with any intent of committing hostilities, but in a peaceable manner. However, when he came to al Hodeibiya, which is situate partly within and partly without the sacred territory, the Koreish sent to let him know that they would not permit him to enter Mecca, unless he forced his way; whereupon he called his troops about him, and they all took a solemn oath of fealty or homage to him, and he resolved to attack the city; but those of Mecca sending Arwa Ebn Masud, prince of the tribe of Thakif, as their ambassador, to desire peace, a truce was concluded between them for ten years, by which any person was allowed to enter into league either with Mohammed, or with the Koreish, as he thought fit.

It may not be improper, to shew the inconceivable veneration and respect the Mohammedans by this time had for their prophet, to mention the account which the above-mentioned ambassador gave the Koreish, at his return, of their behaviour. He said he had been at the courts both of the Roman emperor and of the king of Persia, and never saw any prince so highly respected by his subjects as Mohammed was by his companions; for, whenever he made the ablution, in order to say his prayers, they ran and caught the water that he had used; and, whenever he spit, they immediately licked it up, and gather-

ed up every hair that fell from him with great superstition.

In the seventh year of the Hejra, Mohammed began to think of propagating his religion beyond the bounds of Arabia, and sent messengers to the neighbouring princes, with letters to invite them to Mohammedism. Nor was this project without some success. Khofru Parviz, then king of Persia, received his letter with great disdain, and tore it in a passion, sending away the messenger very abruptly; which when Mohammed heard, he said, *God shall tear his kingdom*. And soon after a messenger came to Mohammed from Badhan king of Yaman, who was a dependent on the Persians, to acquaint him that he had received orders to send him to Khofru. Mohammed put off his answer till the next morning, and then told the messenger it had been revealed to him that night that Khofru was slain by his son Shiruyeh; adding, that he was well assured his new religion and empire should rise to as great a height as that of Khofru; and therefore bid him advise his master to embrace Mohammedism. The messenger being returned, Badhan in a few days received a letter from Shiruyeh, informing him of his father's death, and ordering him to give the prophet no further disturbance. Whereupon Badhan and the Persians with him turned Mohammedans.

The emperor Heraclius, as the Arabian historians assure us, received Mohammed's letter with great respect, laying it on his pillow, and dismissed the bearer honourably. And some pretend that he would have professed this new faith, had he not been afraid of losing his crown.

Mohammed wrote to the same effect to the king of Ethiopia, though he had been converted before, according to the Arab writers; and to Mokawkas, governor of Egypt, who gave the messenger a very favourable reception, and sent several valuable presents to Mohammed, and among the rest two girls, one of which, named Mary, became a great favourite with him. He also sent letters of the like purport to several Arab princes; particularly one to al Hareth Ebn Abi Shamer king of Ghassan, who returning for answer that he would go to Mohammed himself, the prophet said, *May his kingdom perish*; another to Hawdha Ebn Ali, king of Yamama, who was a Christian, and, having some time before professed Islamism, had lately returned to his former faith; this prince felt back a very rough answer, upon which Mohammed cursing him, he died soon after; and a third to al Mondar Ebn Sawa, king of Bahrein, who embraced Mohammedism, and all the Arabs of that country followed his example.

The eighth year of the Hejra was a very fortunate year to Mohammed. In the beginning of it, Khaled Ebn al Walid and Amru Ebn al As, both excellent soldiers, the first of whom afterwards conquered Syria and other countries, and the latter Egypt, became proselytes of Mohammedism. And soon after the prophet sent 3000 men against the Grecian forces, to revenge the death of one of his ambassadors, who being sent to the governor of Bofra on the same errand as those who went to the above-mentioned princes, were slain by an Arab, of the tribe of Ghassan, at Muta, a town in the territory of Balka in Syria about three days journey eastward from Jerusalem, near which town they encountered. The Grecians being vastly superior in number (for, including the auxiliary

Arabs, they had an army of 100,000 men) the Mohammedans were repulsed in the first attack, and lost successively three of their generals, viz. Zeid Ebn Haretha Mohammed's freedman, Jaafar the son of Abu Taleb, and Abdallah Ebn Rawaha; but Khaled Ebn al Walid, succeeding to the command, overthrew the Greeks with a great slaughter, and brought away abundance of rich spoil; on occasion of which action Mohammed gave him the honourable title of *Scif min soyuf Allah, one of the swords of God*.

In this year also Mohammed took the city of Mecca, the inhabitants whereof had broken the truce concluded on two years before. For the tribe of Becr, who were confederates with the Koreish, attacking those of Khozaah, who were allies of Mohammed, killed several of them, being supported in the action by a party of the Koreish themselves. The consequence of this violation was soon apprehended; and Abu Sofian himself made a journey to Medina on purpose to heal the breach and renew the truce; but in vain: for Mohammed, glad of this opportunity, refused to see him: whereupon he applied to Abu Becr and Ali; but they giving him no answer, he was obliged to return to Mecca as he came.

Mohammed immediately gave orders for preparations to be made, that he might surprise the Meccans while they were unprovided to receive him: in a little time he began his march thither, and by that time he came near the city his forces were increased to 10,000 men. Those of Mecca, being not in a condition to defend themselves against so formidable an army, surrendered at discretion; and Abu Sofian saved his life by turning Mohammedan. About twenty-eight of the idolaters were killed by a party under the command of Khaled; but this happened contrary to Mohammed's orders, who, when he entered the town, pardoned all the Koreish, on their submission, except only six men and four women, who were more obnoxious than ordinary (some of them having apostatized) and were solemnly proscribed by the prophet himself; but of these no more than threemen and one woman were put to death, the rest obtaining pardon on their embracing Mohammedism, and one of the women making her escape.

The remainder of this year Mohammed employed in destroying the idols in and round Mecca, sending several of his generals on expeditions for that purpose, and to invite the Arabs to Islamism; wherein it is no wonder if they now met with success.

The next year, being the ninth of the Hejra, the Mohammedans call *the year of embassies*: for the Arabs had been hitherto expecting the issue of the war between Mohammed and the Koreish; but, so soon as that tribe, the principal of the whole nation, and the genuine descendants of Ithmael, whose prerogatives none offered to dispute, had submitted, they were satisfied that it was not in their power to oppose Mohammed, and therefore began to come in to him in great numbers, and to send embassies to make their submissions to him, both to Mecca, while he staid there, and also to Medina, whither he returned this year. Among the rest; five kings of the tribe of Hamyar professed Mohammedism, and sent ambassadors to notify the same.

In the tenth year Ali was sent into Yaman to propagate the Mohammedan faith there, and, as it is said, converted the whole tribe of Hamdan in one day. Their example was quickly followed by all the inhabitants of that province, except only those of Najran, who, being Christians, chose rather to pay tribute.

Thus was Mohammedism established, and idolatry rooted out, even in Mohammed's life-time (for he died the next year) throughout all Arabia, except only Yama-ma, where Moseilama, who set up also for a prophet as Mohammed's competitor, had a great party, and was not reduced till the Khalifat of Abu Becr: and the Arabs, being then united in one faith and under one prince, found themselves in a condition of making those conquests, which extended the Mohammedan faith over so great a part of the world.

Of the Koran. The word *Koran*, derived from the verb *karaa*, to read, signifies properly, in Arabic, the reading, or, rather, that which ought to be read; by which name the Mohammedans denote not only the entire book or volume of the Koran, but also any particular chapter or section of it; just as the Jews call either the whole scripture, or any part of it, by the name of *Karah*, or *Mikra*, words of the same origin and import. See AL-KORAN.

Before this peculiar name, the Koran is also honoured with several appellations, common to other books of scripture: as, *al Farkan*, from the verb *foraka*, to divide or distinguish; not, as the Mohammedan doctors say, because those books are divided into chapters or sections, or distinguish between good and evil; but in the same notion that the Jews use the word *Perek*, or *Pirka*, from the same root, to denote a section or portion of scripture. It is also called *al Moshaf*, the volume, and *all Kirab*, the book, by way of eminence, which answers to the *Biblia* of the Greeks; and *al Dhikr*, the admonition, which name is also given to the Pentateuch and Gospel.

The Koran is divided into 114 larger portions of very unequal length, which we call *chapters*, but the Arabians *Sowar*, in the singular *Sura*, a word rarely used on any other occasion, and properly signifying a row, order, or a regular series; as a course of bricks in building, or a rank of soldiers in an army; and is the same in use and import with the *Sura*, or *Tora* of the Jews, who also call the fifty three sections of the Pentateuch *Sedarim*, a word of the same signification.

These chapters are not in the manuscript copies distinguished by their numerical order, but by particular titles, which are taken sometimes from a particular matter treated of, or person mentioned therein; but usually from the first word of note, exactly in the same manner as the Jews have named their *Sedarim*; though the word from which some chapters are denominated be very far distant, towards the middle, or perhaps the end of the chapter; which seems ridiculous. But the occasion of this seems to have been, that the verse or passage wherein such word occurs, was, in point of time, revealed and committed to writing before the other verses of the same chapter which precede it in order; and the title being given to the chapter before it was completed, or the passages re-

duced to their present order, the verse from whence such title was taken did not always happen to begin the chapter. Some chapters have two or more titles, occasioned by the difference of the copies.

Some of the chapters having been revealed at Mecca, and others at Medina, the noting this difference makes a part of the title: but the reader will observe that several of the chapters are said to have been revealed partly at Mecca, and partly at Medina; and, as to others, it is yet a dispute among the commentators to which place of the two they belong.

Every chapter is subdivided into smaller portions, of very unequal length also, which we customarily call *verses*: but the Arabic word is *Ayat*, the same with the Hebrew *Ototh*, and signifies *signs*, or *wonders*; such as are the secrets of God, his attributes, works, judgments, and ordinances, delivered in those verses; many of which have their particular titles also, imposed in the same manner as those of the chapters.

Besides these unequal divisions of chapter and verse, the Mohammedans have also divided their Koran into sixty equal portions, which they call *Abzab*, in the singular *Hizb*, each subdivided into four equal parts; which is also an imitation of the Jews, who have an ancient division of their Mishna into sixty portions called *Massekoth*: but the Koran is more usually divided into thirty sections only, named *Ajza*, from the singular *Joz*, each of twice the length of the former, and in the like manner subdivided into four parts. These divisions are for the use of the readers of the Koran in the royal temples, or in the adjoining chapels where the emperors and great men are interred. There are thirty of these readers belonging to every chapel, and each reads his section every day, so that the whole Koran is read over once a-day.

Next after the title, at the head of every chapter, except only the ninth, is prefixed the following solemn form, by the Mohammedans called the *Bismallah*, IN THE NAME OF THE MOST MERCIFUL GOD; which form they constantly place at the beginning of all their books and writings in general as a peculiar mark or distinguishing characteristic of their religion, it being counted a sort of impiety to omit it. The Jews, for the same purpose, make use of the form, *In the name of the LORD, or, In the name of the great God*: and the eastern Christians that of, *In the name of the Father, and of the Son, and of the Holy Ghost*. But Mohammed probably took this form, as he did many other things, from the Persian Magi, who used to begin their books in these words, *Benam Yazdan bakhshai/gyher dadar*; that is, *In the name of the most merciful just God*.

There are twenty-nine chapters of the Koran, which have this peculiarity, that they begin with certain letters of the alphabet, some with a single one, others with more. These letters the Mohammedans believe to be the peculiar marks of the Koran, and to conceal several profound mysteries, the certain understanding of which, the more intelligent confess, has not been communicated to any mortal, their prophet only excepted. Notwithstanding which, some will take the liberty of guessing at their meaning by that species of Cabala called by the Jews *Notarikon*, and suppose the letters to stand for as many words, expressing

Expressing the names and attributes of God, his works, ordinances, and decrees; and therefore these mysterious letters, as well as the verses themselves, seem in the Koran to be called signs. Others explain the intent of these letters from their nature or organ, or else from their value in numbers, according to another species of the Jewish Cabala called Gematria; the uncertainty of which conjectures sufficiently appears from their disagreement. Thus, for example, five chapters, one of which is the second, begin with these letters, A. L. M. which some imagine to stand for, *Allah latif magid*; God is gracious and to be glorified; or, *Ana li minni, to me and from me*, viz. belongs all perfection, and proceeds all good; or else for *Ana Allah alam, I am the most wise God*, taking the first letter to mark the beginning of the first word, the second the middle of the second word, and the third the last of the third word; or for *Allah, Gabriel, Mohammed*, the author, revealer, and preacher of the Koran. Others say, that as the letter A belongs to the lower part of the throat, the first of the organs of speech; L to the palate, the middle organ; and M to the lips, which are the last organ; so these letters signify that God is the beginning, middle, and end, or ought to be praised in the beginning, middle, and end, of all our words and actions: or, as the total value of those three letters, in numbers, is seventy one, they signify, that, in the space of so many years, the religion preached in the Koran should be fully established. The conjecture of a learned Christian is at least as certain as any of the former, who supposes those letters were set there by the amanuensis, for *Anwar li Mohammed*, i. e. *At the command of Mohammed*, as the five letters prefixed to the nineteenth chapter seem to be there written by a Jewish scribe, for *Coh yaar*, i. e. *Thus he commanded*.

The Koran is universally allowed to be written with the utmost elegance and purity of language, in the dialect of the tribe of Koreish, the most noble and polite of all the Arabians, but with some mixture, though very rarely, of other dialects. It is confessedly the standard of the Arabic tongue, and, as the more orthodox believe, and are taught by the book itself, inimitable by any human pen, (though some sectaries have been of another opinion) and therefore insisted on as a permanent miracle, greater than that of raising the dead, and alone sufficient to convince the world of its divine original.

And to this miracle did Mohammed himself chiefly appeal for the confirmation of his mission, publicly challenging the most eloquent men in Arabia, which was at that time stocked with thousands, whose sole study and ambition it was to excel in elegance of style and composition, to produce even a single chapter that might be compared with it.

The general design of the Koran seems to be this: to unite the professors of the three different religions then followed in the populous country of Arabia, who, for the most part, lived promiscuously, and wandered without guides, the far greater number being idolaters, and the rest Jews and Christians mostly of erroneous and heterodox belief, in the knowledge and worship of one eternal, invisible God, by whose power all things were made, and those which are not may be; the supreme

Governor, Judge, and absolute Lord of the creation; established under the sanction of certain laws, and the outward signs of certain ceremonies, partly of ancient, and partly of novel institution, and enforced by setting before them rewards and punishments, both temporal and eternal: and to bring them all to the obedience of Mohammed, as the prophet and ambassador of God, who, after the repeated admonitions, promises and threats of former ages, was at last to establish and propagate God's religion on earth by force of arms, and to be acknowledged chief pontiff in spiritual matters, as well as supreme prince in temporal.

The great doctrine then of the Koran is the unity of God; to restore which point Mohammed pretended was the chief end of his mission; it being laid down by him, as a fundamental truth, that there never was, nor ever can be, more than one true orthodox religion. For, though the particular laws or ceremonies are only temporary, and subject to alteration, according to the divine direction; yet, the substance of it, being eternal truth, is not liable to change, but continues immutably the same. And he taught, that, whenever this religion became neglected, or corrupted in essentials, God had the goodness to re-inform and re-admonish mankind thereof, by several prophets, of whom Moses and Jesus were the most distinguished, till the appearance of Mohammed, who is their seal, no other being to be expected after him. And the more effectually to engage people to hearken to him, great part of the Koran is employed in relating examples of dreadful punishments formerly inflicted by God on those who rejected and abused his messengers; several of which stories, or some circumstances of them, are taken from the Old and New Testament, but many more from the apocryphal books and traditions of the Jews and Christians of those ages, set up in the Koran as truths in opposition to the scriptures, which the Jews and Christians are charged with having altered; and indeed few or none of the relations or circumstances in the Koran were invented by Mohammed, as is generally supposed, it being easy to trace the greatest part of them much higher, as the rest might be, were more of those books extant, and it was worth while to make the inquiry.

The other part of the Koran is taken up in giving necessary laws and directions, in frequent admonitions to moral and divine virtues, and, above all, to the worshipping and reverencing of the only true God, and resignation to his will; among which are many excellent things intermixed, not unworthy even a Christian's perusal.

But besides these, there are a great number of passages which are occasional, and relate to particular emergencies. For whenever any thing happened which perplexed and grieved Mohammed, and which he could not otherwise get over, he had constant recourse to a new revelation, as an infallible expedient in all nice cases; and he found the success of this method answer his expectation. It was certainly an admirable and politic contrivance of his to bring down the whole Koran at once to the lowest heaven only, and not to the earth as a bungling prophet would probably have done: for if the whole had been published at once, innumerable objections might have been made, which it would have been very hard, if not impossible,

impossible, for him to solve : but as he pretended to have received it by parcels, as God saw proper that they should be published for the conversion and instruction of the people, he had a sure way to answer all emergencies, and to extricate himself with honour from any difficulty which might occur.

That Mohammed was really the author and chief contriver of the Koran, is beyond dispute ; though it be highly probable that he had no small assistance in his design from others, as his countrymen failed not to object to him ; however, they differed so much in their conjectures as to the particular persons who gave him such assistance, that they were not able, it seems, to prove the charge ; Mohammed, it is to be presumed, having taken his measures too well to be discovered. Dr. Prideaux has given the most probable account of this matter, though chiefly from Christian writers, who generally mix such ridiculous fables with what they deliver, that they deserve not much credit.

However it be, the Mohammedans absolutely deny the Koran was composed by their prophet himself, or any other for him ; it being their general and orthodox belief that it is of divine original, nay, that it is eternal and uncreated, remaining, as some express it, in the very essence of God ; that the first transcript has been from everlasting by God's throne, written on a table of vast bigness, called the *preserved table*, in which are also recorded the divine decrees past and future : that a copy from this table, in one volume on paper, was by the ministry of the angel Gabriel sent down to the lowest heaven, in the month of Ramadan, on the night of *power* : from whence Gabriel revealed it to Mohammed by parcels, some at Mecca, and some at Medina, at different times, during the space of twenty-three years, as the exigency of affairs required ; giving him, however, the consolation to shew him the whole (which they tell us was bound in silk, and adorned with gold and precious stones of paradise) once a year ; but in the last year of his life he had the favour to see it twice. They say that few chapters were delivered entire, the most part being revealed piece-meal, and written down from time to time by the prophet's amanuenses in such or such a part of such or such a chapter till they were completed, according to the directions of the angel. The first parcel that was revealed is generally agreed to have been the first five verses of the ninety-sixth chapter.

After the new revealed passages had been from the prophet's mouth taken down in writing by his scribe, they were published to his followers, several of whom took copies for their private use, but the far greater number got them by heart. The originals, when returned, were put promiscuously into a chest, observing no order of time, for which reason it is uncertain when many passages were revealed.

When Mohammed died, he left his revelations in the same disorder, and not digested into the method, such as it is, which we now find in it. This was the work of his successor Abu Becr, who, considering that a great number of passages were committed to the memory of Mohammed's followers, many of whom were slain in their wars, ordered the whole to be collected, not only

from the palm-leaves and skins on which they had been written, and which were kept between two boards or covers, but also from the mouths of such as had gotten them by heart. And this transcript, when completed, he committed to the custody of Hafsa the daughter of Omar, one of the prophet's widows.

From this relation it is generally imagined that Abu Becr was really the compiler of the Koran ; though, for aught appears to the contrary, Mohammed left the chapters complete as we now have them, excepting such passages as his successor might add or correct from those who had gotten them by heart ; what Abu Becr did else being, perhaps, no more than to range the chapters in their present order, which he seems to have done with out any regard to time, having generally placed the longest first.

However, in the thirtieth year of the Hejra, Othman being then Khalif, and observing the great disagreement in the copies of the Khoran in the several provinces of the empire, those of Irak, for example, following the reading of Abu Musa al Ashari, and the Syrians that of Maadad Ebn Aswad, he, by advice of the *companions*, ordered a great number of copies to be transcribed from that of Abu Becr, in Hafsa's care, under the inspection of Zeid Ebn Thabet, Abd'allah Ebn Zobair, Said Ebn al As, and Ad'alrahman Ebn al Hareth the Makhzumite ; whom he directed, that, where ever they disagreed about any word, they should write it in the dialect of the Koreish, in which it was at first delivered. These copies, when made, were dispersed in the several provinces of the empire, and the old ones burnt and suppressed. Though many things in Hafsa's copy were corrected by the above-mentioned supervisors, yet some few various readings still occur.

The fundamental position, on which Mohammed erected the superstructure of his religion, was, That, from the beginning to the end of the world, there has been, and for ever will be, but one true orthodox belief ; consisting, as to matter of faith, in the acknowledging of the only true God, and the believing in and obeying such messengers or prophets as he should from time to time send, with proper credentials, to reveal his will to mankind ; and, as to matter of practice, in the observance of the immutable and eternal laws of right and wrong, together with such other precepts and ceremonies as God should think fit to order for the time being, according to the different dispensations in different ages of the world : for these last, he allowed, were things indifferent in their own nature, and became obligatory by God's positive precept only ; and were therefore temporary, and subject to alteration, according to his will and pleasure. And to this religion he gives the name of Islam, which word signifies *resignation*, or *submission* to the service and commands of God ; and is used as the proper name of the Mohammedan religion, which they will also have to be the same at bottom with that of all the prophets from Adam.

Under pretext that this eternal religion was in his time corrupted, and professed in its purity by no one sect of men, Mohammed pretended to be a prophet sent by God, to reform those abuses which had crept into it, and to reduce it to its primitive simplicity ; with the addition
however

however of peculiar laws and ceremonies, some of which had been used in former times, and others were now first instituted. And he comprehended the whole substance of his doctrine under these two propositions, or articles of faith, *viz.* that there is but one God, and that himself was the apostle of God; in consequence of which latter article, all such ordinances and institutions as he thought fit to establish must be received as obligatory and of divine authority.

The Mohammedans divide their religion, which they call Islam, into two distinct parts; Iman, i. e. *faith*, or theory; and Din, i. e. *religion*, or practice; and teach that it is built on five fundamental points, one belonging to faith, and the other four to practice.

The first is, that *there is no god but the true God*; and that Mohammed is his apostle. Under which they comprehend six distinct branches, *viz.* 1. *Belief in God*; 2. *In his angels*; 3. *In his scriptures*; 4. *In his prophets*; 5. *In the resurrection and day of judgment*; and, 6. *In God's absolute decree and predetermination both of good and evil.*

The four points relating to practice are, 1. Prayer, under which are comprehended those washings or purifications which are necessary preparations required before prayer; 2. Alms; 3. Fasting; and, 4. The pilgrimage to Mecca.

That both Mohammed, and those among his followers who are reckoned orthodox, had and continue to have just and true notions of God and his attributes, appears plain from the Koran itself, and all the Mohammedan divines, that it would be loss of time to refute those who suppose the God of Mohammed to be different from the true God, and only a fictitious deity, or idol of his own creation.

The existence of angels, and their purity, are absolutely required to be believed in the Koran; and he is reckoned an infidel who denies there are such beings, or hates any of them, or asserts any distinction of sexes among them. They believe them to have pure and subtle bodies, created of fire; that they neither eat nor drink, nor propagate their species; that they have various forms and offices; some adoring God in different postures, others singing praises to him, or interceding for mankind. They hold, that some of them are employed in writing down the actions of men, others in carrying the throne of God and other services.

The four angels, whom they look on as more eminent in God's favour, and often mention on account of the offices assigned them, are Gabriel, to whom they give several titles, particularly those of the *holy spirit*, and the *angel of revelations*, supposing him to be honoured by God with a greater confidence than any other, and to be employed in writing down the divine decrees; Michael, the friend and protector of the Jews; Azrael, the *angel of death*, who separates mens souls from their bodies; and Israfil, whose office it will be to sound the trumpet at the resurrection. The Mohammedans also believe, that two guardian angels attend on every man, to observe and write down his actions, being changed every day, and therefore called al Moakibat, or the angels who continually succeed one another.

The devil, whom Mohammed names Eblis, from his *despair*, was once one of those angels who are nearest to God's presence, called Azazil; and fell, according to the doctrine of the Koran, for refusing to pay homage to Adam at the command of God.

Besides angels and devils, the Mohammedans are taught by the Koran to believe an intermediate order of creatures, which they call Jin or Genii, created alfo of fire, but of a grosser fabric than angels; since they eat and drink, and propagate their species, and are subject to death. Some of these are supposed to be good, and others bad, and capable of future salvation or damnation, as men are; whence Mohammed pretended to be sent for the conversion of genii as well as men.

As to the scriptures, the Mohammedans are taught by the Koran, that God, in divers ages of the world, gave revelations of his will in writing to several prophets, the whole and every word of which it is absolutely necessary for a good Moslem to believe. The number of these sacred books were, according to them, 104. Of which ten were given to Adam, fifty to Seth, thirty to Edris or Enoch, ten to Abraham; and the other four, being the Pentateuch, the Psalms, the Gospel, and the Koran, were successively delivered to Moses, David, Jesus, and Mohammed; which last being the seal of the prophets, those revelations are now closed, and no more are to be expected. All these divine books, except the four last, they agree to be now entirely lost, and their contents unknown; though the Sabians have several books which they attribute to some of the antediluvian prophets. And of those four, the Pentateuch, Psalms, and Gospel, they say, have undergone so many alterations and corruptions, that, though there may possibly be some part of the true word of God therein, yet no credit is to be given to the present copies in the hands of the Jews and Christians. The Mohammedans have also a gospel in Arabic, attributed to St Barnabas, wherein the history of Jesus Christ is related in a manner very different from what we find in the true Gospels, and correspondent to those traditions which Mohammed has followed in his Koran. Of this Gospel the Moriscoes in Africa have a translation in Spanish; and there is, in the library of prince Eugene of Savoy, a manuscript of some antiquity, containing an Italian translation of the same Gospel, made, it is to be supposed, for the use of renegades. This book appears to be no original forgery of the Mohammedans, though they have no doubt interpolated and altered it since, the better to serve their purpose; and in particular, instead of the Paraclete or Comforter, they have in this apocryphal gospel inserted the word Periclyte, that is, the *famous or illustrious*, by which they pretend their prophet was foretold by name, that being the signification of Mohammed in Arabic: and this they say to justify that passage of the Koran, where Jesus Christ is formally asserted to have foretold his coming, under his other name of Ahmed, which is derived from the same root as Mohammed, and of the same import. From these or some other forgeries of the same stamp, it is that the Mohammedans quote several passages, of which there are not the least footprints in the *New Testament*.

The number of the prophets, which have been from time

time to time sent by God into the world, amounts to no less than 224,000, according to one Mohammedan tradition, or to 124,000, according to another; among whom 313 were apostles, sent with special commissions to reclaim mankind from infidelity and superstition; and six of them brought new laws or dispensations, which successively abrogated the preceding: these were Adam, Noah, Abraham, Moses, Jesus, and Mohammed. All the prophets in general, the Mohammedans believe to have been free from great sins and errors of consequence, and professors of one and the same religion, that is, Islam, notwithstanding the different laws and institutions which they observed. They allow of degrees among them, and hold some of them to be more excellent and honourable than others. The first place they give to the revealers and establishers of new dispensations, and the next to the apostles.

In this great number of prophets, they not only reckon divers patriarchs and persons named in scripture, but not recorded to have been prophets, (wherein the Jewish and Christian writers have sometimes led the way,) as Adam, Seth, Lot, Isaac, Nun, Joshua, &c. and introduce some of them under different names, as Enoch, Heber, and Jethro, who are called, in the Koran, Edris, Hud, and Shoaib; but several others whose very names do not appear in scripture (though they endeavour to find some persons there to fix them on) as, Saleh, Khedr, Dhu'lkifl, &c.

The next article of faith required by the Koran is the belief of a general resurrection and a future judgment.

When a corpse is laid in the grave, they say he is received by an angel, who gives him notice of the coming of the two Examiners; which are two black livid angels, of a terrible appearance, named Monk and Nakir. These order the dead person to sit upright, and examine him concerning his faith, as to the unity of God, and the mission of Mohammed: if he answer rightly, they suffer the body to rest in peace, and it is refreshed by the air of paradise; but, if not, they beat him on the temples with iron maces, till he roars out for anguish so loud that he is heard by all from east to west, except men and genii. Then they press the earth on the corpse, which is gnawed and stung till the resurrection by ninety-nine dragons, with seven heads each; or, as others say, their fins will become venomous beasts, the grievous ones stinging like dragons, the smaller like scorpions, and the others like serpents: circumstances which some understand in a figurative sense.

As to the soul, they hold, that, when it is separated from the body by the angel of death, who performs his office with ease and gentleness towards the good, and with violence towards the wicked, it enters into that state which they call al Berzakh, or the interval between death and the resurrection. If the departed person was a believer, they say two angels meet it, who convey it to heaven, that its place there may be assigned, according to its merit and degree. For they distinguish the souls of the faithful into three classes; the first of prophets, whose souls are admitted into paradise immediately; the second of martyrs, whose spirits, according to a tradition of Mohammed, rest in the crops of green birds, which eat

of the fruits and drink of the rivers of paradise; and the third of other believers, concerning the state of whose souls before the resurrection there are various opinions.

Though some among the Mohammedans have thought that the resurrection will be merely spiritual, and no more than the returning of the soul to the place whence it first came (an opinion defended by Ebn Sina, and called by some the *opinion of the philosophers*;) and others, who allow man to consist of body only, that it will be merely corporeal; the received opinion is, that both body and soul will be raised; and their doctors argue strenuously for the possibility of the resurrection of the body. and dispute with great subtilty concerning the manner of it. But Mohammed has taken care to preserve one part of the body, whatever becomes of the rest, to serve for a basis of the future edifice, or rather a haven for the mass which is to be joined to it. For he taught, that a man's body was entirely consumed by the earth, except only the bone called al Ajb, which we name the *os coccygis*, or rump bone; and that, as it was the first formed in the human body, it will also remain uncorrupted till the last day, as a seed from whence the whole is to be renewed: and this, he said, would be effected by a forty days rain, which God should send, and which would cover the earth to the height of twelve cubits, and cause the bodies to sprout forth like plants. Herein, also, is Mohammed beholden to the Jews; who say the same things of the bone Luz, excepting that what he attributes to a great rain, will be effected, according to them, by a dew, impregnating the dust of the earth.

The time of the resurrection the Mohammedans allow to be a perfect secret to all but God alone; the angel Gabriel himself acknowledging his ignorance in this point, when Mohammed asked him about it. However, they say, the approach of that day may be known from certain signs which are to precede it. These signs they distinguish into two sorts, the lesser, and the greater.

The lesser signs are, 1. The decay of faith among men. 2. The advancing of the meanest persons to eminent dignity. 3. That a maid servant shall become the mother of her mistress (or master;) by which is meant, either that towards the end of the world men shall be much given to sensuality, or that the Mohammedans shall then take many captives. 4. Tumults and seditions. 5. A war with the Turks. 6. Great distress in the world, so that a man when he passes by another's grave, shall say, Would to God I were in his place. 7. That the provinces of Irak and Syria shall refuse to pay their tribute. And, 8. That the buildings of Medina shall reach to Ahab, or Yahab.

The greater signs are,

1. The sun's rising in the west; which some have imagined it originally did.

2. The appearance of the beast, which shall rise out of the earth, in the temple of Mecca, or on mount Safa, or in the territory of Tayef, or some other place. This beast, they say, is to be sixty cubits high; though others, not satisfied with so small a size, will have her reach to the clouds and to heaven, when her head only is out; and that she will appear for three days, but shew only a third part of her body. They describe this monster, as

† D to

to her form, to be a compound of various species ; having the head of a bull, the eyes of a hog, the ears of an elephant, the horns of a stag, the neck of an ostrich, the breast of a lion, the colour of a tiger, the back of a cat, the tail of a ram, the legs of a camel, and the voice of an ass. Some say this beast is to appear three times in several places, and that she will bring with her the rod of Moses and the seal of Solomon ; and, being so swift that none can overtake or escape her, will with the first strike all the believers on the face, and mark them with the word mumen, *i. e.* believer ; and with the latter will mark the unbelievers on the face likewise, with the word Cafer, *i. e.* *infidel*, that every person may be known for what he really is. They add, that the same beast is to demonstrate the vanity of all religions except Islam, and to speak Arabic. All this stuff seems to be the result of a confused idea of the beast in the Revelations.

3. War with the Greeks, and the taking Constantinople by 70,000 of the posterity of Isaac, who shall not win that city by force of arms, but the walls shall fall down while they cry out, *There is no God but God : God is most great !* As they are dividing the spoil, news will come to them of the appearance of Antichrist ; whereupon they shall leave all, and return back.

4. The coming of Antichrist, whom the Mohammedans call Masib al Dajjal, *i. e.* the false or lying Christ, and simply al Dajjal. He is to be one-eyed, and marked on the forehead with the letters C. F. R. signifying Cafer, or infidel. They say that the Jews give him the name of Messiah Ben David, and pretend he is to come in the last days, and to be lord both of land and sea, and that he will restore the kingdom to them.

5. The descent of Jesus on earth. They pretend that he is to descend near the white tower to the east of Damascus, when the people are returned from the taking of Constantinople ; that he is to embrace the Mohammedan religion, marry a wife, get children, kill Antichrist, and at length die after forty years, or, according to others, twenty four years continuance on earth. Under him, they say, there will be great security, and plenty in the world, all hatred and malice being laid aside ; when lions and camels, bears and sheep, shall live in peace, and a child shall play with serpents unharmed.

6. War with the Jews ; of whom the Mohammedans are to make a prodigious slaughter, the very trees and stones discovering such of them as hide themselves, except only the tree called Gharkad, which is the tree of the Jews.

7. The eruption of Gog and Magog, or, as they are called in the east, Yajuj and Majuj ; of whom many things are related in the Koran and the traditions of Mohammed. These barbarians, they tell us, having passed the lake of Tiberias, which the vanguard of their vast army will drink dry, will come to Jerusalem, and there greatly distress Jesus and his companions ; till, at his request, God will destroy them, and fill the earth with their carcases, which, after some time, God will send birds to carry away, at the prayers of Jesus and his followers. Their bows, arrows, and quivers, the Moslems will burn for seven years together ; and at last, God will send a rain to cleanse the earth, and to make it fertile.

8. A smoke, which shall fill the whole earth.

9. An eclipse of the moon. Mohammed is reported to have said, that there would be three eclipses before the last hour ; one to be seen in the east, another in the west, and the third in Arabia.

10. The returning of the Arabs to the worship of Allat and al Uzza, and the rest of their ancient idols, after the decease of every one in whose heart there was faith equal to a grain of mustard-seed, none but the very worst of men being left alive. For God, they say, will send a cold odorous wind, blowing from Syria Damascena, which shall sweep away the souls of all the faithful, and the Koran itself, so that men will remain in the grossest ignorance for an hundred years.

11. The discovery of a vast heap of gold and silver by the retreating of the Euphrates, which will be the destruction of many.

12. The demolition of the Caaba, or temple of Mecca, by the Ethiopians.

13. The speaking of beasts and inanimate things.

14. The breaking out of fire in the province of Hejaz ; or, according to others, in Yaman.

15. The appearance of a man of the descendants of Kahtan, who shall drive men before him with his staff.

16. The coming of the Mohdi, or director ; concerning whom Mohammed prophesied, that the world should not have an end till one of his own family should govern the Arabians, whose name should be the same with his own name, and whose father's name should also be the same with his father's name ; and who should fill the earth with righteousness. This person the Shites believe to be now alive, and concealed in some secret place, till the time of his manifestation ; for they suppose him no other than the last of the twelve Imams, named Mohammed Abu'lkasem, as their prophet was ; and the son of Hassan al Akteri, the eleventh of that succession. He was born at Sermanrai in the 25th year of the Hejra. From this tradition, it is to be presumed, an opinion pretty current among the Christians took its rise, that the Mohammedans are in expectation of their prophet's return.

17. A wind which shall sweep away the souls of all who have but a grain of faith in their hearts, as has been mentioned under the tenth sign.

These are the greater signs, which, according to their doctrine, are to precede the resurrection, but still leave the hour of it uncertain ; for the immediate sign of its being come will be the first blast of the trumpet ; which they believe will be sounded three times. The first they call the *blast of conformation* ; at the hearing of which all creatures in heaven and earth shall be struck with terror, except those whom God shall please to exempt from it. The effects attributed to this first sound of the trumpet are very wonderful ; for they say, the earth will be shaken, and not only all buildings, but the very mountains levelled ; that the heavens shall melt, the sun be darkened, the stars fall, on the death of the angels, who, as some imagine, hold them suspended between heaven and earth ; and the sea shall be troubled and dried up, or, according to others, turned into flames, the sun, moon, and stars being thrown into it : the Koran, to express the greatness of the terror of that day, adds, that women who give

give suck shall abandon the care of their infants, and even the she camels which have gone ten months with young (a most valuable part of the substance of that nation) shall be utterly neglected. A farther effect of this blast will be that concourse of beasts mentioned in the Koran, though some doubt whether it be to precede the resurrection or not. They who suppose it will precede, think that all kinds of animals, forgetting their respective natural fierceness and timidity, will run together into one place, being terrified by the sound of the trumpet and the sudden shock of nature.

The Mohammedans believe that this first blast will be followed by a second, which they call the *blast of examination*; when all creatures both in heaven and earth shall die or be annihilated, except those which God shall please to exempt from the common fate; and this, they say, shall happen in the twinkling of an eye, nay in an instant; nothing surviving except God alone, with paradise and hell, and the inhabitants of those two places, and the throne of glory. The last who shall die will be the angel of death.

Forty years after this will be heard the *blast of resurrection*, when the trumpet shall be sounded the third time by Israfil, who, together with Gabriel and Michael, will be previously restored to life, and, standing on the rock of the temple of Jerusalem, shall, at God's command, call together all the dry and rotten bones, and other dispersed parts of the bodies, and the very hairs, to judgment. This angel, having, by the divine order, set the trumpet to his mouth, and called together all the souls from all parts, will throw them into his trumpet, from whence, on his giving the last sound, at the command of God, they will fly forth like bees, and fill the whole space between heaven and earth, and then repair to their respective bodies, which the opening earth will suffer to arise: and the first who shall so arise, according to a tradition of Mohammed, will be himself. For this birth the earth will be prepared by the rain above-mentioned, which is to fall continually for forty years, and will resemble the seed of a man, and be supplied from the water under the throne of God, which is called *living water*; by the efficacy and virtue of which the dead bodies shall spring forth from their graves, as they did in their mother's womb, or as corn sprouts forth by common rain, till they become perfect; after which breath will be breathed into them, and they will sleep in their sepulchres till they are raised to life at the last trumpet.

When those who have risen shall have waited the limited time, the Mohammedans believe God will at length appear to judge them; Mohammed undertaking the office of intercessor, after it shall have been declined by *Adam, Noah, Abraham, and Jesus*, who shall beg deliverance only for their own souls. They say, that on this solemn occasion God will come in the clouds, surrounded by angels, and will produce the books wherein the actions of every person are recorded by their guardian angels, and will command the prophets to bear witness against those to whom they have been respectively sent. Then every one will be examined concerning all his words and actions, uttered and done by him in this life; not as if God needed any information in these respects, but to oblige the per-

son to make public confession and acknowledgment of God's justice. The particulars of which they shall give an account, as Mohammed himself enumerated them, are, of their time, how they spent it; of their wealth, by what means they acquired it, and how they employed it; of their bodies, wherein they exercised them; of their knowledge and learning, what use they made of them. To the questions we have mentioned each person shall answer, and make his defence in the best manner he can, endeavouring to excuse himself by casting the blame of his evil deeds on others; so that a dispute shall arise even between the soul and the body, to which of them their guilt ought to be imputed: the soul saying, *O Lord, my body I received from thee; for thou createdst me without a hand to lay hold with, a foot to walk with, an eye to see with, or an understanding to apprehend with, till I came and entered into this body; therefore punish it eternally, but deliver me.* The body, on the other side, will make this apology: *O Lord, thou createdst me like a stock of wood, having neither hand that I could lay hold with, nor foot that I could walk with, till this soul, like a ray of light, entered into me, and my tongue began to speak, my eye to see, and my foot to walk; therefore punish it eternally, but deliver me.* But God will propound to them the following parable of the blind man and the lame man, which, as well as the preceding dispute, was borrowed by the Mohammedans from the Jews. A certain king, having a pleasant garden, in which were ripe fruits, set two persons to keep it, one of whom was blind, and the other lame; the former not being able to see the fruit, nor the latter to gather it: the lame man, however, seeing the fruit, persuaded the blind man to take him upon his shoulders and by that means he easily gathered the fruit; which they divided between them. The lord of the garden coming some time after, and inquiring after his fruit, each began to excuse himself; the blind man said he had no eyes to see with, and the lame man that he had no feet to approach the trees. But the king, ordering the lame man to be set on the blind, passed sentence on and punished them both. And in the same manner will God deal with the body and the soul. As these apologies will not avail on that day, so will it also be in vain for any one to deny his evil actions, since men and angels, and his own members, nay, the very earth itself, will be ready to bear witness against him.

At this examination they also believe, that each person will have the book wherein all the actions of his life are written delivered to him; which books the righteous will receive in their right hand, and read with great pleasure and satisfaction; but the ungodly will be obliged to take them, against their wills, in their left, which will be bound behind their backs, their right hand being tied up to their necks,

To shew the exact justice which will be observed on this great day of trial, the next thing they describe is the *balance*, wherein all things shall be weighed. They say it will be held by Gabriel; and that it is of so vast a size, that its two scales, one of which hangs over paradise, and the other over hell, are capacious enough to contain both heaven and earth. Though some are willing to understand what is said in the Koran concerning this,

this balance allegorically, and only as a figurative representation of God's equity; yet the more ancient and orthodox opinion is, that they are to be taken literally; and since words and actions, being mere accidents, are not capable of being themselves weighed, they say that the books wherein they are written will be thrown into the scales, and according as those wherein the good or evil actions are recorded shall preponderate, sentence will be given: those whose balances laden with good works shall be heavy, will be saved; but those whose balances are light, will be condemned. Nor will any one have cause to complain that God suffers any good action to pass unrewarded, because the wicked for the good they do have their reward in this life, and therefore can expect no favour in the next.

This examination being past, and every one's works weighed in a just balance, that mutual retaliation will follow, according to which every creature will take vengeance one of another, or have satisfaction made them for the injuries which they have suffered. And, since there will then be no other way of returning like for like, the manner of giving this satisfaction will be by taking away a proportional part of the good works of him who offered the injury, and adding it to those of him who suffered it. Which being done, if the angels (by whose ministry this is to be performed) say, *Lord, we have given to every one his due, and there remaineth of this person's good works so much as equalleth the weight of an ant*, God will, of his mercy, cause it to be doubled unto him, that he may be admitted into paradise; but if, on the contrary, his good works be exhaulted, and there remain evil works only, and there be any who have not yet received satisfaction from him. God will order that an equal weight of their sins be added unto his, that he may be punished for them in their stead, and he will be sent to hell laden with both. This will be the method of God's dealing with mankind. As to brutes, after they shall have likewise taken vengeance of one another, he will command them to be changed into dust; wicked men being reserved to more grievous punishment, so that they shall cry out, on hearing this sentence passed on the brutes, *Would to God that we were dust also*. As to the genii, many Mohammedans are of opinion, that such of them as are true believers, will undergo the same fate as the irrational animals, and have no other reward than the favour of being converted into dust; and for this they quote the authority of their prophet.

The trials being over, and the assembly dissolved, the Mohammedans hold, that those who are to be admitted into paradise will take the right hand way, and those who are destined to hell fire will take the left; but both of them must first pass the bridge called in Arabic *al Sirat*, which they say is laid over the midst of hell, and describe to be finer than a hair, and sharper than the edge of a sword; so that it seems very difficult to conceive how any one shall be able to stand upon it: for which reason, most of the sect of the Motazalites reject it as a fable; though the orthodox think it a sufficient proof of the truth of this article, that it was seriously affirmed by him who never asserted a falsehood, meaning their prophet; who, to add to the difficulty of the passage, has likewise declared, that this

bridge is beset on each side with briars and hooked thorns; which will however be no impediment to the good, for they shall pass with wonderful ease and swiftness, like lightning, or the wind, Mohammed and his Moslems leading the way; whereas the wicked, what with the slipperiness and extreme narrowness of the path, the intangling of the thorns, and the extinction of the light which directed the former to paradise, will soon miss their footing, and fall down headlong into hell, which is gaping beneath them.

As to the punishment of the wicked, the Mohammedans are taught, that hell is divided into seven stories or apartments, one below another, designed for the reception of as many distinct classes of the damned. The first, which they call *Jehennam*, they say, will be the receptacle of those who acknowledged one God, that is, the wicked Mohammedans, who, after having there been punished according to their demerits, will at length be released. The second, named *Ladha*, they assign to the Jews; the third, named *al Hotama*, to the Christians; the fourth, named *al Sair*, to the Sabians; the fifth, named *Sakar*, to the Magians; the sixth, named *al Jahim*, to the idolaters; and the seventh, which is the lowest and worst of all, and is called *al Hawyat*, to the hypocrites, or those who outwardly professed some religion, but in their hearts were of none. Over each of these apartments they believe there will be set a guard of angels, nineteen in number: to whom the damned will confess the just judgment of God, and beg them to intercede with him for some alleviation of their pain, or that they may be delivered by being annihilated.

Mohammed has, in his Koran and traditions, been very exact in describing the various torments of hell, which, according to him, the wicked will suffer both from intense heat and excessive cold. We shall however enter into no detail of them here, but only observe, that the degrees of these pains will also vary in proportion to the crimes of the sufferer, and the apartment he is condemned to; and that he who is punished the most lightly of all will be shod with shoes of fire, the fervor of which will cause his skull to boil like a cauldron. The condition of these unhappy wretches, as the same prophet teaches, cannot be properly called either life or death; and their misery will be greatly increased by their despair of being ever delivered from that place, since, according to that frequent expression in the Koran, *they must remain therein for ever*. It must be remarked, however, that the infidels alone will be liable to eternity of damnation; for the Moslems, or those who have embraced the true religion, and have been guilty of heinous sins, will be delivered thence after they shall have expiated their crimes by their sufferings. The time which these believers shall be detained there, according to a tradition handed down from their prophet, will not be less than 900 years, nor more than 7000. And, as to the manner of their delivery, they say that they shall be distinguished by the marks of prostration on those parts of their bodies with which they used to touch the ground in prayer, and over which the fire will therefore have no power; and that, being known by this characteristic, they will be released by the mercy of God, at the intercession

cession of Mohammed and the blessed; whereupon those who shall have been dead, will be restored to life, as has been said; and those whose bodies shall have contracted any footnefs or filth from the flames and smoke of hell, will be immersed in one of the rivers of paradise, called the *river of life*, which will wash them whiter than pearls.

The righteous, as the Mohammedans are taught to believe, having surmounted the difficulties, and passed the sharp bridge above-mentioned, before they enter paradise, will be refreshed by drinking at the *pond* of their prophet, who describes it to be an exact square of a month's journey in compass; its water, which is supplied by two pipes from al Cawthar, one of the rivers of paradise, being whiter than milk or silver, and more odoriferous than musk, with as many cups set around it as there are stars in the firmament; of which water whoever drinks will thirst no more for ever. This is the first taste which the blessed will have of their future and now near approaching felicity.

Though paradise be so very frequently mentioned in the Koran, yet it is a dispute among the Mohammedans whether it be already created, or be to be created hereafter; the Motazalites and some other sectaries asserting that there is not at present any such place in nature, and that the paradise which the righteous will inhabit in the next life will be different from that from which Adam was expelled. However, the orthodox profess the contrary, maintaining that it was created even before the world, and describe it, from their prophet's traditions, in the following manner.

They say it is situate above the seven heavens (or in the seventh heaven) and next under the throne of God; and, to express the amenity of the place, tell us, that the earth of it is of the finest wheat flour, or of the purest musk, or, as others will have it, of saffron: that its stones are pearls and jacinths, the walls of its buildings enriched with gold and silver, and that the trunks of all its trees are of gold; among which the most remarkable is the tree called Tuba, or the tree of happiness. Concerning this tree, they fable, that it stands in the palace of Mohammed, though a branch of it will reach to the house of every true believer; that it will be laden with pomegranates, grapes, dates, and other fruit, of surprising bigness, and of tastes unknown to mortals. So that, if a man desire to eat of any particular kind of fruit, it will immediately be presented him; or, if he chuse flesh, birds ready dressed will be set before him, according to his wish. They add, that the boughs of this tree will spontaneously bend down to the hand of the person who would gather of its fruits, and that it will supply the blessed not only with food, but also with silken garments, and beasts to ride on ready saddled and bridled, and adorned with rich trappings, which will burst forth from its fruits; and that this tree is so large, that a person, mounted on the swiftest horse, would not be able to gallop from one end of its shade to the other in a hundred years.

As plenty of water is one of the greatest additions to the pleasantness of any place, the Koran often speaks of the rivers of paradise as a principal ornament thereof: some of these rivers, they say, flow with water, some

with milk, some with wine, and others with honey; all taking their rise from the root of the tree Tuba.

But all these glories will be eclipsed by the refulgent and ravishing girls of paradise, called, from their large black eyes, *Hur al ayn*, the enjoyment of whose company will be a principal felicity of the faithful. These, they say, are created, not of clay, as mortal women are, but of pure musk; being, as their prophet often affirms in his Koran, free from all natural impurities, defects, and inconveniences incident to the sex, of the strictest modesty, and secluded from public view in pavilions of hollow pearls, so large, that, as some traditions have it, one of them will be no less than four parasangs (or, as others say, sixty miles) long, and as many broad.

The name which the Mohammedans usually give to this happy mansion, is *al Jannat*, or the garden; and sometimes they call it, with an addition, *Jannat al Ferdaws*, the garden of paradise; *Jannat Aden*, the garden of Eden, (though they generally interpret the word *Eden*, not according to its acceptation in Hebrew, but according to its meaning in their own tongue, where-in it signifies a settled or perpetual habitation:); *Jannat al Ma'wa*, the garden of abode; *Jannat al Naim*, the garden of pleasure; and the like: by which several appellations, some understand so many different gardens, or at least places of different degrees of felicity, (for they reckon no less than an hundred such in all,) the very meanest whereof will afford its inhabitants so many pleasures and delights, that one would conclude they must even sink under them, had not Mohammed declared, that, in order to qualify the blessed for a full enjoyment of them, God will give to every one the abilities of an hundred men.

The sixth great point of faith, which the Mohammedans are taught by the Koran to believe, is God's absolute decree and predestination both of good and evil. For the orthodox doctrine is, that whatever hath or shall come to pass in this world, whether it be good, or whether it be bad, proceedeth entirely from the divine will, and is irrevocably fixed and recorded from all eternity in the preserved table: God having secretly predetermined not only the adverse and prosperous fortune of every person in this world, in the most minute particulars, but also his faith or infidelity, his obedience or disobedience, and consequently his everlasting happiness or misery after death; which fate or predestination it is not possible, by any foresight or wisdom, to avoid.

Of this doctrine Mohammed makes great use in his Koran for the advancement of his designs; encouraging his followers to fight without fear, and even desperately, for the propagation of their faith, by representing to them that all their caution could not avert their inevitable destiny, or prolong their lives for a moment; and deterring them from disobeying or rejecting him as an impostor, by setting before them the danger they might thereby incur of being, by the just judgment of God, abandoned to seduction, hardness of heart, and a reprobate mind, as a punishment for their obstinacy.

Of the four fundamental points of religious practice required by the Koran, the first is *prayer*, under which are also comprehended those legal washings or purifications which are necessary preparations thereto.

Of these purifications there are two degrees, one called *Ghoß*, being a total immersion or bathing of the body in water; and the other called *Wodu*, (by the Persians, *Abdest*;) which is the washing of their faces, hands, and feet, after a certain manner. The first is required in some extraordinary cases only, as after having lain with a woman, or been polluted by emission of seed, or by approaching a dead body; women also being obliged to it after their courses or childbirth. The latter is the ordinary ablution in common cases, and before prayer, and must necessarily be used by every person before he can enter upon that duty. It is performed with certain formal ceremonies, which have been described by some writers, but much easier apprehended by seeing them done, than by the best description.

That his followers might be more punctual in this duty, Mohammed is said to have declared, that *the practice of religion is founded on cleanliness*, which is *the one half of the faith*, and *the key of prayer*, without which it will not be heard by God. That these expressions may be the better understood, *al Ghazali* reckons four degrees of purification; of which the first is the cleansing of the body from all pollution, filth, and excrements; the second, the cleansing of the members of the body from all wickedness and unjust actions; the third, the cleansing the heart from all blameable inclinations and odious vices; and the fourth, the purging a man's secret thoughts from all affections which may divert their attendance on God: adding, that the body is but as the outward shell, in respect to the heart, which is as the kernel.

Circumcision, though it be not so much as once mentioned in the Koran, is yet held, by the Mohammedans, to be an ancient divine institution, confirmed by the religion of Islam, and, though not so absolutely necessary but that it may be dispensed with in some cases, yet highly proper and expedient. The Arabs used this rite for many ages before Mohammed, having probably learned it from Ishmael, though not only his descendants, but the Hamyarites and other tribes practised the same. The Ishmaelites, we are told, used to circumcise their children, not on the eighth day, as is the custom of the Jews, but when about twelve or thirteen years old, at which age their father underwent that operation; and the Mohammedans imitate them so far as not to circumcise children before they be able at least distinctly to pronounce that profession of their faith, *There is no God but God*, Mohammed is *the apostle of God*; but pitch on what age they please for the purpose, between fix or sixteen, or thereabouts.

Prayer was, by Mohammed, thought so necessary a duty, that he used to call it *the pillar of religion*, and *the key of paradise*; and when the Thakifites, who dwelt at Tayef, sending, in the ninth year of the Hejra, to make their submission to that prophet, after the keeping of their favourite idol had been denied them, begged, at least, that they might be dispensed with as to their saying of their appointed prayers, he answered, *That there could be no god in that religion wherein was no prayer*.

That so important a duty, therefore, might not be neglected, Mohammed obliged his followers to pray five times every twenty-four hours, at certain stated times;

viz. 1. In the morning, before sun-rise: 2. When noon is past, and the sun begins to decline from the meridian: 3. In the afternoon, before sun set: 4. In the evening, after sun-set, and before day be shut in: and, 5. After the day is shut in, and before the first watch of the night. For this institution he pretended to have received the divine command from the throne of God himself, when he took his night-journey to heaven; and the observing of the stated times of prayer is frequently insisted on in the Koran, though they be not particularly prescribed therein. Accordingly, at the aforesaid times, of which public notice is given by the Mueddhins, or Criers, from the steeples of their Mosques, (for they use no bells,) every conscientious Moslem prepares himself for prayer, which he performs either in the Mosque or any other place, provided it be clean, after a prescribed form, and with a certain number of praises or ejaculations, (which the more scrupulous count by a string of beads and using certain postures of worship;) all which have been particularly set down and described, though with some few mistakes, by other writers, and ought not to be abridged, unless in some special cases, as on a journey, on preparing for battle, &c.

For the regular performance of the duty of prayer among the Mohammedans, besides the particulars above-mentioned, it is also requisite that they turn their faces, while they pray, towards the temple of Mecca; the quarter where the lame is situate being, for that reason, pointed out within their mosques by a niche, which they call *al Mehrah*; and without, by the situation of the doors opening into the galleries of the steeples: there are, also, tables calculated for the ready finding out their Keblah, or part towards which they ought to pray, in places where they have no other direction.

The next point of the Mohammedan religion is the giving of alms; which are of two sorts, *legal* and *voluntary*. The *legal alms* are of indispensable obligation, being commanded by the law, which directs and determines both the portion which is to be given, and of what things it ought to be given; but the *voluntary alms* are left to every one's liberty, to give more or less, as he shall see fit. The former kind of alms some think to be properly called *Zacat*, and the latter *Sadakāt*; though this name be also frequently given to the legal alms. They are called *Zacat*, either because they *increase* a man's store by drawing down a blessing thereon, and produce in his soul the virtue of liberality; or because they *purify* the remaining part of one's substance from pollution, and the soul from the filth of avarice; and *Sadakāt*, because they are a proof of a man's sincerity in the worship of God. Some writers have called the legal alms *tithe*, but improperly, since in some cases they fall short, and in others exceed that proportion.

The third point of religious practice is fasting; a duty of so great moment, that Mohammed used to say it was *the gate of religion*, and that *the odour of the mouth of him who fasteth is more grateful to God than that of musk*; and *al Ghazali* reckons fasting one fourth part of the faith. According to the Mohammedan divines, there are three degrees of fasting: 1. The restraining the belly and other parts of the body from satisfying their lusts; 2. The restraining the ears, eyes, tongue, hands, feet, and o-

ther

ther members from sin; and, 5. The fasting of the heart from worldly cares, and retraining the thoughts from every thing besides God.

The Mohammedans are obliged, by the express command of the Koran, to fast the whole month of Ramadan, from the time the new moon first appears, till the appearance of the next new moon; during which time they must abstain from eating, drinking, and women, from day-break till night or sun-set. And this injunction they observe so strictly, that, while they fast, they suffer nothing to enter their mouths, or other parts of their body, esteeming the fast broken and null, if they smell perfumes, take a clyster or injection, bathe, or even purposely swallow their spittle: some being so cautious, that they will not open their mouths to speak, lest they should breathe the air too freely: the fast is also deemed void, if a man kifs or touch a woman, or if he vomit willingly. But after sun-set they are allowed to refresh themselves, and to eat and drink, and enjoy the company of their wives till day-break; though the more rigid begin the fast again at midnight. This fast is extremely rigorous and mortifying when the month of Ramadan happens to fall in summer, (for, the Arabian year being lunar, each month runs through all the different seasons in the course of thirty-three years) the length and heat of the days making the observance of it much more difficult and uneasy than in winter.

The reason given why the month of Ramadan was pitched on for this purpose is, that on that month the Koran was sent down from heaven. Some pretend that Abraham, Moses, and Jesus, received their respective revelations in the same month.

The pilgrimage to Mecca is so necessary a point of practice, that, according to a tradition of Mohammed, he who dies without performing it may as well die a Jew or a Christian; and the same is expressly commanded in the Koran.

The temple of Mecca stands in the midst of the city, and is honoured with the title of Masjad al elharam, i. e. *the sacred or inviolable temple*. What is principally revered in this place, and gives sanctity to the whole, is a square stone building called the Caaba, as some fancy, from its height, which surpasses that of the other buildings in Mecca; but more probably from its quadrangular form, and Beit Allah, i. e. *the house of God*, being peculiarly hallowed and set apart for his worship. The length of this edifice, from north to south, is twenty-four cubits, its breadth from east to west twenty-three cubits, and its height twenty-seven cubits: the door, which is on the east side, stands about four cubits from the ground; the floor being level with the bottom of the door. In the corner next this door is the *black stone*. On the north side of the Caaba, within a semicircular inclosure fifty cubits long, lies the *white stone*, said to be the sepulchre of Ishmael, which receives the rain water that falls off the Caaba by a spout, formerly of wood, but now of gold. The Caaba has a double roof, supported within by three octangular pillars of aloes wood; between which, on a bar of iron, hang some silver lamps. The outside is covered with rich black damask, adorned with an embroidered band of gold, which is changed every

year, and was formerly sent by the Khalifs, afterwards by the Sultans of Egypt, and is now provided by the Turkish emperors. At a small distance from the Caaba, on the east side, is the *station or place of Abraham*, where is another stone much respected by the Mohammedans, of which something will be said hereafter.

The Caaba, at some distance, is surrounded, but not entirely, by a circular inclosure of pillars joined towards the bottom by a low balustrade, and towards the top by bars of silver. Just without this inner inclosure, on the south, north, and west sides of the Caaba, are three buildings, which are the oratories or places where three of the orthodox sects assemble to perform their devotions, (the fourth sect, *viz.* that of al Shafei, making use of the station of Abraham for that purpose;) and, towards the south-east, stands the edifice which covers the well Zemzem, the treasury, and the cupola of al Abbas.

All these buildings are inclosed, at a considerable distance, by a magnificent piazza, or square colonnade, like that of the Royal Exchange in London, but much larger, covered with small domes or cupolas; from the four corners whereof rise as many minarets or steeples, with double galleries, and adorned with gilded spires and crests, as are the cupolas which cover the piazza and the other buildings. Between the pillars of both inclosures hang a great number of lamps, which are constantly lighted at night.

This is properly all that is called the temple; but, the whole territory of Mecca being also Haram or sacred, there is a third inclosure distinguished at certain distances by small turrets, some five, some seven, and others ten miles distant from the city. Within this compass of land it is not lawful to attack an enemy, or even to hunt or fowl, or cut a branch from a tree.

The temple of Mecca was a place of worship, and in singular veneration with the Arabs, from great antiquity, and many centuries before Mohammed. Though it was most probably dedicated at first to an idolatrous use, yet the Mohammedans are generally persuaded that the Caaba is almost coeval with the world.

After this edifice had undergone several reparations, it was a few years after the birth of Mohammed rebuilt by the Koreish on the old foundation, and afterwards repaired by Abd'allah Ebn Zobeir, the Khalif of Mecca; and at length again rebuilt by Yusuf, surnamed al Hejaj, in the seventy-fourth year of the Hejra, with some alterations, in the form wherein it now remains. Some years after, however, the Khalif Harun al Rashid (or, as others write, his father al Mohdi, or his grandfather al Manfur) intended again to change what had been altered by al Hejaj, and to reduce the Caaba to the old form in which it was left by Abd'allah; but was dissuaded from meddling with it, lest so holy a place should become the sport of princes, and, being new-modelled after every one's fancy, should lose that reverence which was justly paid it. But, notwithstanding the antiquity and holiness of this building, they have a prophecy, by tradition from Mohammed, that in the last times the Ethiopians shall come and utterly demolish it; after which it will not be rebuilt again for ever.

Before we leave the temple of Mecca, two or three particulars

particulars deserve further notice. One is the celebrated *black stone*, which is set in silver, and fixed in the south-east corner of the Caaba, being that which looks toward Bafra, about two cubits and one third, or, which is the same thing, seven spans from the ground. This stone is exceedingly respected by the Mohammedans, and is kissed by the pilgrims with great devotion, being called by some the *right hand of God on earth*. They fable, that it is one of the precious stones of paradise, and fell down to the earth with Adam, and, being taken up again, or otherwise preferred at the deluge, the angel Gabriel afterwards brought it back to Abraham, when he was building the Caaba. It was at first whiter than milk, but grew black long since by the touch of a menstruous woman, or, as others tell us, by the sins of mankind; or rather by the touches and kisses of so many people; the superficies only being black, and the inside still remaining white.

To this temple every Mohammedan, who has health and means sufficient, ought once, at least, in his life to go on pilgrimage; nor are women excused from the performance of this duty. The pilgrims meet at different places near Mecca, according to the different parts from whence they come, during the months of Shawal and Dhu'lkaada; being obliged to be there by the beginning of Dhu'lhajja; which month, as its name imports, is peculiarly set apart for the celebration of this solemnity.

At the place above-mentioned the pilgrims properly commence such; when the men put on the Ihram or sacred habit, which consists only of two woollen wrappers, one wrapped about their middle to cover their privities, and the other thrown over their shoulders, having their heads bare, and a kind of slippers which cover neither the heel nor the instep, and so enter the sacred territory in their way to Mecca. While they have this habit on, they must neither hunt nor fowl, (though they are allowed to fish;) which precept is so punctually observed, that they will not kill even a louse or a flea, if they find them on their bodies: there are some noxious animals, however, which they have permission to kill during the pilgrimage, as kites, ravens, scorpions, mice, and dogs given to bite. During the pilgrimage, it behoves a man to have a constant guard over his words and actions, and to avoid all quarrelling or ill language, and all converse with women and obscene discourse, and to apply his whole intention to the good work he is engaged in.

The pilgrims, being arrived at Mecca, immediately visit the temple, and then enter on the performance of the prescribed ceremonies; which consist chiefly in going in procession round the Caaba, in running between the mounts Safa and Merwa, in making the station on mount Arafat, and slaying the victims, and shaving their heads in the valley of Mina.

In compassing the Caaba, which they do seven times, beginning at the corner where the black stone is fixed, they use a short quick pace the three first times they go round it, and a grave ordinary pace the four last; which, it is said, was ordered by Mohammed, that his followers might hew themselves strong and active, to cut off the hopes of the infidels, who gave out, that the immoderate heats of Medina had rendered them weak. But the a-

foreaid quick pace they are not obliged to use every time they perform this piece of devotion, but only at some particular times. So often as they pass by the black stone, they either kiss it, or touch it with their hand, and kiss that.

The running between Safa and Merwa is also performed seven times, partly with a slow pace, and partly running: for they walk gravely till they come to a place between two pillars; and there they run, and afterwards walk again; sometimes looking back, and sometimes stopping, like one who has lost something, to repelent Hagar seeking water for her son; for the ceremony is said to be as ancient as her time.

On the ninth of Dhu'lhajja, after morning prayer, the pilgrims leave the valley of Mina, whither they come the day before, and proceed in a tumultuous and rushing manner to mount Arafat, where they stay to perform their devotions till sun-set: then they go to Mozdalifa, an oratory between Arafat and Mina; and there they spend the night in prayer, and reading the Koran. The next morning by day-break they visit al Masher al haram or the *sacred monument*, and, departing thence before sunrise, haste by Batn Mohaffer to the valley of Mina, where they throw seven stones at three marks or pillars, in imitation of Abraham, who, meeting the devil in that place, and being by him disturbed in his devotions, or tempted to disobedience, when he was going to sacrifice his son, was commanded by God to drive him away by throwing stones at him; though others pretend this rite to be as old as Adam, who also put the devil to flight in the same place and by the same means.

This ceremony being over, on the same day, the tenth of Dhu'lhajja, the pilgrims slay their victims in the said valley of Mina; of which they and their friends eat part, and the rest is given to the poor. These victims must be either sheep, goats, kine, or camels; males, if of either of the two former kinds; and females, if of either of the latter; and of a fit age. The sacrifices being over, they shave their heads and cut their nails, burying them in the same place; after which the pilgrimage is looked on as completed; though they again visit the Caaba, to take their leave of that sacred building.

MAIDEN, an instrument used in Scotland for beheading criminals.

This is a broad piece of iron, about a foot square, very sharp on the lower part, and loaded above with a very heavy weight of lead. At the time of execution it is pulled up to the top of a narrow wooden frame, about ten feet high, and as broad as the engine, with mouldings on each side for the maiden to slide in. A convenience is made about four feet from the ground, for the prisoner to lay his neck; and there is a kind of bar so fastened as to keep him from stirring. The prisoner being thus secured, and the sign given, the maiden is let loose, which in a moment separates his head from his body.

MAIDSTONE, the county-town of Kent, situated on the Medway, twenty-two miles west of Canterbury: E. long. 37°, N. lat. 51° 20'. It sends two members to parliament.

MAJESTY,

MAJESTY, a title given to kings, which frequently serves as a term of distinction.

Thus the emperor is called Sacred Majesty, Imperial Majesty, and Cæsarian Majesty: the king of France is called his Most Christian Majesty, and when he treats with the emperor, the word Sacred is added; and the king of Spain is termed his Most Catholic Majesty: with respect to other kings, the name of the kingdom is added, as his Britannic Majesty, his Polish Majesty, &c. Formerly princes were more sparing in giving titles, and more modest in claiming them: before the reign of Charles V. the kings of Spain had only the title of Highness; and before that of Henry VIII. the kings of England were only addressed under the title of Grace and Highness.

MAIL, or coat of MAIL, a piece of defensive armour for the body, made of small iron rings, interwoven in the manner of a net.

Action of Mails and Duties, in Scots law. See LAW, Tit. xxx. 20.

MAINE, a river of Germany, which rises on the east side of the circle of Franconia and running from east to west discharges itself into the Rhine at Mentz.

MAINPRISE, in law, is the receiving a person into friendly custody, who might otherwise be committed to prison, on security given that he shall be forthcoming at a certain time and place appointed.

MAJOR, in the art of war, the name of several officers of very different ranks and functions; as 1. Major general, the next officer to the lieutenant general: his chief business is to receive the orders from the general, or in his absence from the lieutenant general of the day; which he is to distribute to the brigade-majors, with whom he is to regulate the guards, convoys, and detachments. When there are two attacks at a siege, he commands that on the left. He ought to be well acquainted with the strength of each brigade, of each regiment in particular, and to have a list of all the field officers. In short, he is in the army what a major is in a regiment. He is allowed an aid de camp, and has a serjeant and fifteen men for his guard. 2. Major of a brigade, the officer who receives the orders from the major-general, and afterwards delivers them to the adjutants of the regiments at the head of the brigade: where he takes and marches the detachments, &c. to the general rendezvous. He ought to be an expert captain, to know the state and condition of the brigade, and keep a roll of the colonels, lieutenant-colonels, majors, and adjutants. 3. Major of a regiment, the next officer to the lieutenant-colonel, generally promoted from the oldest captain. He is to take care that the regiment be well exercised, to see it march in good order, and to rally it in case of its being broke. He is the only officer among the foot that is allowed to be on horseback in time of action, that he may the more readily execute the colonel's orders, either in advancing or drawing off the regiment. 4. Major of a regiment of horse, is the first captain, who commands in the absence of the colonel. 5. Town-major, the third officer in a garrison, being next to the deputy-governor. He ought to understand fortification, and

have charge of the guards, rounds, patrols, &c. His business is also to take care that the soldiers arms are in good order; he likewise orders the gates to be opened and shut, and gives the governor an account of all that passes within the place.

There are also aids major, drums-major, &c. so called from their preeminence above others of the same denomination.

MAJOR, in logic, the first proposition of a syllogism. See LOGIC.

MAJORANA, in botany. See ORIGANUM.

MAJORCA, the capital of a Spanish island of the same name: E. long. 2° 30', N. lat. 39° 30'.

This island is in the Mediterranean sea, about sixty miles long, and forty five broad, situated about eighty miles south of the coast of Catalonia, and an hundred miles east of Valencia.

MAIRE, or *strights of Le Maire*, is a passage to Cape Horn, situated between Terra del Fuego in South America, and Statten island; which being discovered by Le Maire, obtained his name.

MAIZ See ZEA

MALA, the cheek, in anatomy. See ANATOMY, p. 160.

MALABAR, the south west coast of the peninsula of hither India, about 400 miles long, and 100 broad, bounded by Vissapour on the north, by the mountains of Baligate, on the east; and by the Indian ocean on the west and south.

MALACCA, the most southerly part of the further peninsula of India, about 600 miles long, and generally about 200 miles broad; bounded by Siam, on the north; by the bay of Siam and the Indian ocean, on the east; and by the freights of Malacca, on the south-west. The capital of this country, which is also commonly called Malacca, is situated in 100° of E. long. and 2° 30' N. lat.

MALACHI, or the prophecy of MALACHI, a canonical book of the old Testament, and the last of the twelve lesser prophets. Malachi prophesied about three hundred years before Christ, reproving the Jews for their wickedness after their return from Babylon, charging them with rebellion, sacrilege, adultery, prophaneness, and infidelity, and condemning the priests for being scandalously careless in their ministry: at the same time not forgetting to encourage the pious few, who, in that corrupt age, maintained their integrity. This prophet distinctly points at the Messiah, who was suddenly to come to his temple, and to be introduced by Elijah the prophet. that is, by John the Baptist, who came in the spirit and power of Elias or Elijah.

MALACIA, in medicine, is a languishing disorder incident to pregnant women, in which they long sometimes for one kind of food, and sometimes for another, and eat it with an extraordinary greediness.

MALACOPTERYGIOUS, among ichthyologists, an appellation given to such fishes as have the rays of their fins bony, but not pointed or sharp at the extremities, like those of acanthopterygious fishes.

MALACOSTOMOUS FISHES, those destitute of teeth in the jaws, called in English leather-mouthed; as the tench, carp, bream, &c.

MALAGA, a city and port of Spain, in the province of Granada, situated in the Mediterranean, sixty-six miles north-east of Gibraltar: W. long. $4^{\circ} 45'$, N. lat. $36^{\circ} 40'$.

MALAGMA, a cataplasm. See **CATAPLASM**.

MALAMOCCA, a small island and port-town in the lagoons of Venice, situated five miles south of that city.

MALDIVA-ISLANDS, are about a thousand small islands in the Indian ocean, 500 miles south-west of the continent of the hither India, extending from the second degree of south latitude, to the seventh degree of north latitude.

MALDON, a port-town of Essex, ten miles east of Chelmsford. It sends two members to parliament.

MALE, among zoologists, that sex of animals which has the parts of generation without the body.

MALIGNANT, among physicians, a term applied to diseases of a very dangerous nature, and generally infectious: such are the dysentery, hospital-fever, &c. in their worst stages.

MALL, or **SEA-MALL**, in ornithology. See **LARUS**.

MALLEABLE, a property of metals, whereby they are capable of being extended under the hammer.

MALLEUS, in anatomy. See **ANATOMY**, p. 297.

MALLOW, in botany. See **MALVA**.

MALMSBURY, a borough-town of Wiltshire, thirty miles south-west of Salisbury: it sends two members to parliament.

MALO, or **St MALO**, a city and port-town of France, in the province of Britany, situated on a rock, in the English channel, but joined to the continent by a causeway: W. long. 2° , N. lat. $48^{\circ} 40'$.

MALOPE, in botany, a genus of the monadelphia polyandria class. It has a double calix, the exterior one having three leaves; and the capsule contains but one seed. There is only one species, a native of Mauritania.

MALPIGHIA, in botany, a genus of the decandria trigynia class. The calix consists of five leaves, and the corolla of five roundish petals; and the berry has one cell and three seeds. There are nine species, none of them natives of Britain.

MALPLAQUET, a village in the Austrian Netherlands, in the province of Hainault, about seven miles from Mons.

MALT. See **BREWING**.

MALTA, the capital of a small island of the same name in the Mediterranean, is situated in E long 15° , N. lat. $35^{\circ} 15'$; consisting of three towns, separated by channels, which form so many peninsulas of solid rock, rising a great height above the sea.

Knights of MALTA, otherwise called *Hospitalers of St. John of Jerusalem*, a religious military order, whose residence is in the island of Malta. The order consists of three estates, the knights, chaplains, and servants at arms: there are also priests who officiate in the churches; friar-servants, who assist at the offices; and donnes, or demicrosses; but these are not reckoned constituent parts of the body. The government of the order is mixt, being partly monarchical, and partly aristocratical: the grand master is sovereign. The knights

formerly consisted of eight different languages, but now only seven, the English having withdrawn themselves. None are admitted into this order but such as are of noble birth: the knights are of two sorts, those who have a right to be candidates for the dignity of grand master, called grand crosses, and those who are only knights assistants: they never marry, yet have continued from 1090 to the present time. The knights are received into this order, either by undergoing the trials prescribed by statutes, or by dispensation.

MALTON, a borough of Yorkshire, situated on the river Derwent, twenty miles north-east of York. It sends two members to parliament.

MALVA, in botany, a genus of the monadelphia polyandria class. The calix is double, the exterior one consisting of three leaves; and there are many capsules, containing each one seed. There are 22 species, five of them natives of Britain, viz. the sylvestris, or common mallow; the rotundifolia, or dwarf mallow; the parviflora, or small flowered mallow; the alcea, or vervain mallow; and the moschata, or jagged-leaved vervain mallow. The leaves of the mallow are emollient.

MALUS, in botany. See **PYRUS**.

MAMALUKES, the name of a dynasty that reigned in Egypt.

The Mamalukes were originally Turkish and Circassian slaves, bought of the Tartars by Melicahale, to the number of a thousand, whom he bred up to arms, and raised some to the principal offices of the empire. They killed sultan Moadam, to whom they succeeded.

Others say, that the mamalukes were ordinarily chosen from among the Christian slaves, and that they were the same thing in a great measure with the Janissaries among the Turks. They never married. They first are said to have been brought from Circassia, and some have supposed that they began to reign about the year 869.

MAMMÆ, in anatomy. See **ANATOMY**, p. 277.

MAMMEA, in botany, a genus of the polyandria monogynia class. The corolla consists of four petals, and the calix of two leaves; and the berry is large, and contains four seeds. There are two species, none of them natives of Britain.

MAN, in zoology. See **HOMO**.

MANCHESER, a large town of Lancashire, forty miles south-east of Lancaster.

MANDAMUS, in law, a writ that issues out of the court of king's bench, sent to a corporation, commanding them to admit or restore a person to his office.

MANDARINS, a name given to the magistrates and governors of provinces in China, who are chosen out of the most learned men, and whose government is always at a great distance from the place of their birth. Mandarin is also a name given by the Chinese to the learned language of the country; for besides the language peculiar to every province, there is one common to all the learned in the empire, which is in China what Latin is in Europe; this is called the mandarin tongue, or the language of the court.

MANDATE, in law, a judicial commandment to do something. See **MANDAMUS**.

MANDATE, in Scots law. See **LAW**, Tit. xxii. 9.

MAN-

MANDERSCHEIT, a city of Germany, in the electorate of Trier, and the capital of the county of Manderscheit: E. long. 6° 32', N. lat. 50° 20'.

MANDRAGORA, in botany. See **ATROPA**.

MANE, the hair hanging down from a horse's neck; which should be long, thin, and fine; and if frizzled, so much the better.

MANEGE, or **MANAGE**, the exercise of riding the great horse, or the ground feat apart for that purpose; which is sometimes covered, for continuing the exercise in bad weather; and sometimes open, in order to give more liberty and freedom both to the horseman and horse. See **HORSEMANSHIP**.

MANES, in the pagan system of theology, a general name for the infernal deities, or gods of hell.

The ancients comprehended under manes not only Pluto, Proserpine, and Minos, but the souls likewise of the deceased were taken into the number, and esteemed gods of hell. It was usual to erect altars and offer libations to the manes of deceased friends and relations. One branch of the magic art among the pagans consisted in consulting the manes of the dead in matters of importance: this was called Necromancy. See **NECROMANCY**.

MANGIFERA, in botany, a genus of the pentandria monogynia class. The corolla consists of five petals; and the drupa is shaped like a kidney. There is but one species a native of Britain.

MANHEIM, a city of Germany, in the palatinate of the Rhine, situated at the confluence of the Rhine and Neckar: E. long. 7° 20', N. lat. 49° 30'.

MANIA, in medicine. See **MEDICINE**.

MANICHEES, in church-history, a sect of Christian heretics in the third century, the followers of Manes, who made his appearance in the reign of the emperor Probus; pretending to be the comforter whom our Saviour promised to send into the world. He taught that there are two principles, or gods, coeternal and independent on each other, the one the author of all evil, and the other of all good; a doctrine which he borrowed from the Persian magi. He held that our souls were made by the good principle, and our bodies by the evil one; and that the souls of his followers passed through the elements to the moon, and from thence to the sun; where being purified, they then went to God, and became united with his essence; but as for the souls of other men, they either went to hell, or were united to other bodies. He alleged, that Christ had his residence in the sun, the Holy Ghost in the air, wisdom in the moon, and the Father in the abyss of light. He is also charged with denying the resurrection and condemning marriage; with teaching that Christ was the serpent that tempted Eve; with forbidding the use of eggs, cheese, milk, and wine, as proceeding from the bad principle; with using a different kind of baptism from that of the church; with teaching that magistrates were not to be obeyed; and with condemning the most lawful wars.

MANICORDON, or **MANICHORD**, a musical instrument in the form of a spinet; the strings of which, like those of the clavicord, are covered with little pieces

of cloth; to deaden was well as to soften their sound; whence it is also called the dumb spinet.

MANIFESTO, a public declaration made by a prince in writing, shewing his intentions to begin a war, or other enterprise, with the motives that induce him to it, and the reasons on which he founds his rights and pretensions.

MANILLE, in commerce, a large brass-ring in the form of a bracelet, either plain or engraven, flat or round.

Manilles are the principal commodities which the Europeans carry to the coast of Africa, and exchange with the natives for slaves. These people wear them as ornaments on the small of the leg, and on the thick part of the arm above the elbow. The great men wear manilles of gold and silver, but these are made in the country by the natives themselves.

MANIPULUS, in Roman antiquity, a body of infantry, consisting of two hundred men, and constituting the third part of a cohort.

MANIS, the **SCALY LIZARD**, in zoology, a genus of quadrupeds, belonging to the order of Bruta, the characters of which are these: They have no fore-teeth either in the upper or under jaw; the tongue is long and cylindrical: the snout is long and narrow; and the body is covered with hard scales. There are two species, viz.

1. The pentadactyla, or scaly lizard with five toes on each foot. The head is smaller than the neck; the eyes are very small; the length of the body, including the tail, is from six to eight feet. The whole body is covered with hard scales, excepting the under part of the head and neck, the breast, the belly, and the internal side of each leg. Betwixt the scales of this animal, there are some hard hairs like the bristles of a hog, brownish at the points. The scales are of a reddish colour, very hard, convex above, and concave below. All the parts which want scales are naked. The scales are unconnected, and the animal can raise or lower them at pleasure like the quills of the porcupine. When irritated, he erects his scales, and rolls himself up like a hedge-hog. In this situation, neither the tiger, the lion, nor any other animal, is able to hurt him. This creature has nothing forbidding about him but his figure. He is mild and inoffensive, feeding on nothing but worms and other insects. His motion is slow; and he has no other method of escaping the pursuit of man, but by concealing himself in crannies of rocks, and in holes which they dig in the ground, where they likewise bring forth their young. This animal is a native of the East Indies; and are so few in number, that they are seldom to be met with.

2. The tetradactyla, or scaly lizard with four toes on each foot. This species is very similar to the former; only the tail is much longer in proportion to the body, and such parts as want scales, instead of being naked, are covered with a soft hair. It is likewise found in the East Indies. See Plate CIV fig. 4.

MANNA, in the materia medica, the concreted juice of some vegetable, naturally exuding from it, soluble in water, and not inflammable.

It is a honey-like juice, brought to us from Calabria and

and Sicily, sometimes in small granules, or drops of an irregular figure, roundish, oblong, crooked, and sometimes contorted. It should be chosen whitish, or at the utmost with only a faint cast of yellow, not too heavy, in regular dry granules, or in moderately long striz or flakes, of a pleasant taste, and dissolving wholly in the mouth, not leaving a farinacious substance behind it, as much of the common manna does that has been adulterated with honey and flour.

Manna is the mildest and safest of all purges, and may be given to children, to women with child, and to people of the most tender constitutions, with perfect safety; and it never fails gently to move the bowels.

MANOR, an ancient royalty or lordship, formerly called a barony, consisting of demesnes, services, and a court-baron; and comprehending in it messuages, lands, meadow, pasture, wood, rents, an advowson, &c. It may contain one or more villages or hamlets, or only a great part of a village, &c.

MANS, the capital of the territory of Maine, in the province of Orleans in France: E. long. 5', N. lat. 48° 6'

MANSFIELD, a city of Germany, the capital of a county of the same name, in the circle of Upper Saxony: E. long. 11° 45'. N. lat. 51° 36'.

MANSSION, in law, is the chief dwelling house of a lord within his fee, or the capital messuage or manor-house.

MANSLAUGHTER, generally termed homicide, is killing a person without premeditated malice.

MANTELETS, in the art of war, a kind of moveable parapets, made of planks about three inches thick, nailed one over another, to the height of almost six feet, generally cased with tin, and set upon little wheels, so that in a siege they may be driven before the pioneers, and serve as blinds to shelter them from the enemy's small shot.

MANTLE, or **MANTLE-TREE**, in architecture, the lower part of the chimney, or that piece of timber which is laid across the jaumbs, and sustains the compartment of the chimney piece.

MANTLE, or **MANTLING** in heraldry, that appearance of folding of cloth flourishing, or drapery, that is in any achievement drawn about the coat of arms. It is supposed originally to be the representation of a mantle, or military habit, worn by the ancient cavaliers over their armour to preserve it from rust; or, as others hold, a short covering only worn over the helmet, which in after-times was lengthened, and made to hang from the helmet below the whole shield. See Plate CX. fig. 1.

MANTUA, the capital of a duchy of the same name in Italy, is situated in the middle of a lake, formed by the river Mincio, but has a communication with the continent by three causeways: E. long. 11° 15', N. lat. 45° 20'.

MANUMISSION, in Roman antiquity, the act of setting a slave at liberty; which was usually performed before the pretor, who laid his wand called *vindicta*, on the slave's head, and declared him free.

MANUFACTURER, one who works up a natural product into an artificial commodity.

MANURE, any thing used for fattening and improving land. See AGRICULTURE, p. 47.

MANUSCRIPT, in matters of literature, denotes a written book, in contradistinction to a printed one. See Book.

MAP, a plain figure, representing the surface of the earth, or a part thereof, a cording to the laws of perspective. See GEOGRAPHY.

MAPLE, in botany. See ACER.

MAPPARIUS, in Roman antiquity, the officer who gave the signal to the gladiators to begin fighting; which he did by throwing an handkerchief that he had received from the emperor or other magistrate.

MARANTA, in botany, a genus of the monandria monogynia class. The corolla is ringent, and consists of five segments. There are two species, none of them natives of Britain.

MARASMUS, among physicians, denotes an atrophy or consumption, in its last and most deplorable stage.

MARBLE, in natural history, a genus of fossils; being bright and beautiful stones composed of small separate concretions moderately hard, not giving fire with steel, fermenting with and soluble in acid menstrua, and calcining in a slight fire.

The colours of marbles being a very obvious and striking character they are arranged according to them in the following divisions. 1. Of the white plain marbles there are two sorts; the Parian marble of the ancients, and statuary marble of the moderns, an extremely bright and elegant marble; and the Carrara marble, a very fine marble, more compact and close than the former, but less bright. 2. Of the plain yellowish marbles there is only one sort which is a hard, pale yellow, and glossy marble, found in many parts of Italy. 3. Of the bluish and black marbles there are a great many species, as the Chion marble, basaltic, &c. 4. Of the plain green marbles there is only one kind the Lacedemonian marble of the ancients. 5. The pale coloured or whitish brown, commonly called Darby-marble. 6. The green marbles with shells. 7. The black coralloide marble, with and without shells. 8. Of the white variegated marbles there are a great many species, variegated with purple, brown, red, blue, &c. 9. Of the brown variegated marbles there are likewise several sorts, some with red veins, others with white, black, or brown veins. 10. Of the yellow-veined and variegated marbles, some are veined with purple, and others with blue. 11. Of the black variegated marbles, some are veined with white, and others with blue, yellow, red, &c. 12. The green variegated marbles are likewise distinguished by the colour of their veins. 13. The gray spotted marbles are variegated, some with black, and others with green spots. 14. The red variegated marble is the brocatello of the Italians, with white and gold veins.

Colouring of MARBLE. The colouring of marbles is a nice art; and in order to succeed in it, the pieces of marble on which the experiments are tried must be well polished, and clear from the least spot or vein. The harder the marble is, the better it will bear the heat necessary in the operation; therefore alabaster, and

and the common soft white marble, are very improper to perform these operations upon.

Heat is always necessary for the opening the pores of the marble, so as to render it fit to receive the colours: but it must never be made red hot; for then the texture of the marble itself is injured, and the colours are burnt, and lose their beauty. Too small a degree of heat is as bad as too great; for, in this case, tho' the marble receive the colour, it will not be fixed in it, nor strike deep enough. Some colours will strike, even cold; but they are never so well sunk in as when a just degree of heat is used. The proper degree is that which, without making the marble red, will make the liquor boil upon its surface. The menstruums used to strike in the colours must be varied according to the nature of the colour to be used. A lixivium made with horse's or dog's urine, with four parts quick lime, and one part pot-ashes, is excellent for some colours; common lye of wood-ashes does very well for others: for some, spirit of wine is best; and finally, for others, oily liquors, or common white-wine

The colours which have been found to succeed best with the peculiar menstruums, are these: stone blue dissolved in six times the quantity of spirit of wine, or of the urinous lixivium; and that colour which the painters call limous, dissolved in common lye of wood-ashes. An extract of saffron, and that colour made of buckthorn berries, and called by the painters fage-green, both succeed well dissolved in urine and quick-lime, and tolerably well in spirit of wine. Vermilion, and a fine powder of cochineal, succeed also very well in the same liquors. Dragon's blood succeeds very well in spirit of wine, as does also a tincture of logwood in the same spirit. Alkanet root gives a fine colour, but the only menstruum to be used for this is oil of turpentine; for neither spirit of wine, nor any lixivium will do with it. There is another kind of sanguis draconis, called dragon's blood in tears, which, mixed with urine alone, gives a very elegant colour. Besides these mixtures of colours and menstruums, there are some colours which are to be laid on dry and unmixed. These are dragon's blood, of the purest kind, for a red; gamboge for a yellow; green wax for a green; common brimstone, pitch, and turpentine, for a brown colour. The marble, for these experiments, must be made considerably hot, and then the colours are to be rubbed on dry in the lump. Some of these colours, when once given, remain immutable; others are easily changed or destroyed. Thus the red colour given by dragon's blood, or by a decoction of logwood, will be wholly taken away by oil of tartar, and the polish of the marble not hurt by it.

A fine gold colour is given in the following manner: take crude sal armoniac, vitriol, and verdegrease, of each equal quantities; white vitriol succeeds best; and all must be thoroughly mixed in fine powder.

The staining of marble to all the degrees of red or yellow, by solutions of dragon's blood or gamboge, may be done by reducing these gums to powder, and grinding them, with the spirit of wine, in a glass mortar; but for smaller attempts, no method is so good

as the mixing a little of either of these powders with spirit of wine in a silver spoon, and holding it over burning charcoal. By this means a fine tincture will be extracted; and with a pencil dipped in this, the finest traces may be made on the marble while cold, which, on the heating it afterwards either on sand, or in a baker's oven, will all sink very deep, and remain perfectly distinct in the stone. It is very easy to make the ground colour of the marble red or yellow by this means, and leave white veins in it. This is to be done by covering the places where the whitens is to remain with some white paint, or even with two or three doubles only of paper, either of which will prevent the colour from penetrating in that part. All the degrees of red are to be given to marble by means of this gum alone; a slight tincture of it, without the assistance of heat to the marble, gives only a pale flesh colour, but the stronger tinctures give it yet deeper; to this the assistance of heat adds yet greatly; and finally, the addition of a little pitch to the tincture gives it a tendency to blackness, or any degree of deep red that is desired. A blue colour may be given also to marble by dissolving turnsol in a lixivium of lime and urine, or in the volatile spirit of urine; but this has always a tendency to purple, whether made by the one or the other of these ways. A better blue, and used in an easier manner, is furnished by the Canary turnsol, a substance well known among the dyers; this needs only to be dissolved in water, and drawn on the place with a pencil: this penetrates very deep into the marble, and the colour may be increased by drawing the pencil wetted afresh several times over the same lines. This colour is subject to spread and diffuse itself irregularly; but it may be kept in regular bounds, by describing its lines with beds of wax, or any other such substance.

Polishing of MARBLES is performed by first rubbing them well with a free-stone, or sand, till the strokes of the axe are worn off, then with pumice stone, and afterwards with emery.

Arundel-MARBLES, ancient marbles with a chronicle of the city of Athens inscribed on them, many years before our Saviour's birth; presented to the university of Oxford by Thomas earl of Arundel, whence the name.

MARBLING, in general, the painting any thing with veins and clouds, so as to represent those of marble.

Marbling of books or paper is performed thus: Dissolve four ounces of gum arabic into two quarts of fair water; then provide several colours mixed with water in pots or shells, and with pencils peculiar to each colour, sprinkle them by way of intermixture upon the gum-water, which must be put into a trough or some broad vessel; then with a stick curl them, or draw them out in streaks, to as much variety as may be done. Having done this, hold your book or books close together, and only dip the edges in, on the top of the water and colours, very lightly; which done, take them off, and the plain impression of the colours in mixture will be upon the leaves; doing as well the ends as the front of the book in the like manner.

After the same manner you may make marbled paper,

G

†

per,

per, by dipping it on the flat, as also linnen cloth, &c.

Marbling a book on the covers is performed by forming clouds with aqua fortis, or spirit of vitriol mixed with ink, and afterwards glazing the covers.

MARCASITES, in natural history, are defined to be compound inflammable metallic bodies, of a hard and solid substance, of an obscurely and irregularly foliaceous structure, of a bright glittering appearance, naturally constituting whole strata, though sometimes found in detached masses; very freely giving fire with steel; not fermenting with acid menstrooms; and when put into the fire, yielding a blue sulphureous flame, and afterwards calcining into a purple powder. There are only three known species of this genus: 1. The silver-coloured marcasite, found in vast abundance in lead and tin mines. 2. The gold coloured marcasite. 3. The heavy pale-white marcasite.

Marcasites were at first supposed to be almost all pure gold or silver, according to their colour; but experience has shewn, that if they contain any metal at all, no method has hitherto been found of working them to advantage. In Germany, indeed, they extract sulphur and vitriol from the silver marcasite, which two substances are always contained in it; and besides these, it has usually a quantity of arsenic. It has been recommended as a styptic, after being calcined: but as the arsenic may not be all carried off by that operation, its use as a medicine seems extremely dangerous.

MARCGRAVE, or **MARGRAVE**, a degree of honour in Germany answering to our marquiss.

MARGGRAVIA, in botany, a genus of the polyandria monogynia class. The corolla consists of one petal, and the calix consists of six imbricated leaves; and the berry has one cell, containing many seeds. There is but one species, a native of America.

MARCH, in chronology, the third month of the year, consisting of thirty-one days.

MARCHANTIA, in botany, a genus of the cryptogamia algæ class. The calix of the male is peltated, and covered below with monopetalous corollæ; the calix of the female is sessile, bell-shaped, and contains many seeds. There are eight species, four of them natives of Britain, viz. the polymorpha, or common marchantia; the cruciata, or cross-headed marchantia; the hemisphærica, or marsh marchantia; and the conica, or wart marchantia.

MARCHE, a territory of Lyonois, in France, having Berry on the north, Bourbonnois and Auvergne on the east, Limosin on the south, and Poictou on the west.

MARCHPURG, a town of Germany, in the circle of Austria and duchy of Stiria: W. long. 15° 50', N. lat. 47°.

MARCIONITES, Christian heretics in the II^d century, thus denominated from their leader Marcion, who maintained, that there were two principles or gods, a good and a bad one.

MARCOSIANS, a sect of Christian heretics in the II^d century, so called from their leader Marcus, who represented the supreme God as consisting not of a trini-

ty, but a quaternity, viz. the ineffable, silence, the father, and truth.

MARE, the female of the horse kind. See **EQUUS**.

MARGARETTA, one of the largest of the Leeward-islands; it is about fifty miles long, and twenty-four broad, and situated sixty miles north of the continent of Paria, or New Andalusia, in South America: W. long. 64°, and N. lat. 11° 30'.

MARGARITA, the **PEARL**, in natural history. See **PEARL**.

MARGATE, a port-town of Kent, in the isle of Thanet, 12 miles north of Deal.

MARIGNAN, a city and port town of Brazil, the capital of the captainship of Marignan, situated at the mouth of the river St Mary: W. lon. 44°, and S. lat. 2° 15'.

MARINER, the same with sailor. See **SAILOR**.

MARINO, a city of Italy, in the duchy of Urbino, the capital of the territory of Marino, a little state or commonwealth, situated on a mountain in the middle of the Pope's territories: E. long. 13° 30', and N. lat. 44°.

MARJORAM, in botany. See **ORIGANUM**.

MARITIME, something related to, or bounded by the sea: thus, a maritime province, or country, is one bounded by the sea; and a maritime kingdom, or state, is one that makes a considerable figure, or is very powerful at sea. Hence, by maritime powers, among the European states, are understood Great Britain and Holland.

St MARK the evangelist's day, a festival of the Christian church, observed April 25.

St MARK's Gospel, a canonical book of the New Testament, being one of the four gospels.

St Mark wrote his gospel at Rome, where he accompanied St Peter, in the year of Christ 44. Tertullian and others pretend that St Mark was no more than an amanuensis to St Peter, who dictated this gospel to him; others affirm, that he wrote it after St Peter's death. Nor are the learned less divided as to the language this gospel was wrote in; some affirming it was composed in Greek, others in Latin. Several of the ancient heretics received only the gospel of St Mark: others among the catholics rejected the twelve last verses of this gospel. The gospel of St Mark is properly an abridgment of that of St Matthew.

Canons of St Mark, a congregation of regular canons, founded at Mantua, by Albert Spinola a priest, towards the end of the XIIth century. Spinola made a rule for them, which was approved, corrected, and confirmed by several succeeding popes. About the year 1450, they were reformed, and followed only the rule of St Augustine. This congregation having flourished for the space of four hundred years, declined by little and little, and is now become extinct.

Knights of St Mark, an order of knighthood in the republic of Venice, under the protection of St Mark the evangelist. The arms of the order are, gules, a lion winged, or, with this device, **PAX TIBI MARCE EVANGELISTA**. This order is never conferred but on those

those who have done signal service to the commonwealth.

MARK, or **MARC**, also denotes a weight used in several states of Europe, and for several commodities, especially gold and silver. In France, the mark is divided into 8 ounces, or 64 drachms, or 192 deniers or penny weights, or 160 esterlins, or 300 mails, or 640 felins, or 4608 grains. In Holland the mark-weight is also called troy weight, and is equal to that of France. When gold and silver are sold by the mark, it is divided into 25 carats.

MARK is also used among us for a money of account, and in some other countries for a coin.

The English mark is two thirds of a pound sterling, or 13s. 4d. and the Scotch mark is of equal value in Scotch money of account.

MARKET, a public place in a city or town, in which live cattle, provisions, or other goods, are set to sale; and also a privilege, either by grant or prescription, by which a town is enabled to keep a market.

MARLBRO, or **MARLBOROUGH**, a borough town of Wiltshire, eighteen miles north of Salisbury.

It sends two members to parliament.

MARLBRO'-FORT, an English factory on the west coast of the island of Sumatra, three miles east of Bencoolen: E. long. 101°, S. lat. 4° 15'.

MARLE. See **AGRICULTURE**, p. 48.

MARLOW, a borough town of Buckinghamshire, fifteen miles south of Aylesbury. It sends two members to parliament.

MARMALADE, a confection of plumbs, apricots, quinces, &c. boiled with sugar to a consistence.

MARMOR. See **MARBLE**.

MARMORA, a little island of Turkey, situated in the sea of Marmora, to which it gives name, lying sixty miles south-west of Constantinople.

MARMOTTE, in zoology. See **MUS**.

MAROSCH, or **MERISH**, a great river, which, rising in the Carpathian mountains, runs through Transylvania and Hungary, and falls into the river Teyse at Segedin.

MARPURG, a city of Germany, forty miles north of Francfort: E. long. 8°, 40', N. lat. 50° 40'.

MARQUE, or *letters of MARQUE*, in military affairs, are letters of reprisal, granting the subjects of one prince or state liberty to make reprisals on those of another.

Letters of marque among us, are extraordinary commissions granted by authority for reparation to merchants taken and dispoiled by strangers at sea; and reprisals is only the retaking, or taking of one thing for another.

MARQUETRY, or **INLAID-WORK**, is a curious work composed of several fine hard pieces of wood, of various colours, fastened in thin slices on a ground, and sometimes enriched with other matters, as silver, brads, tortoise shell, and ivory: with these assistances the art is now capable of imitating any thing; whence it is by some called the art of painting in wood.

MARQUIS, a title of honour, next in dignity to that of duke, first given to those who commanded the marches, that is, the borders and frontiers of countries.

MARR, that part of Aberdeenshire situated between the rivers Dee and Don.

MARRIAGE, a contract both civil and religious, between a man and a woman, by which they engage to live together in mutual love and friendship, for the ends of procreation, &c. See **LAW**, Tit. vi.

The Romans, as well as the Greeks, disallowed of polygamy. A Roman might not marry any woman who was not a Roman. It was thought dishonourable for a woman to marry twice.

We find but few laws in the books of Moses concerning the institution of marriage: he restrained the Israelites from marrying within certain degrees of consanguinity; but we find, that polygamy, though not expressly allowed, is however tacitly implied in the laws of Moses: there is a particular law that obliged a man, whose brother died without issue, to marry his widow, and raise up children to his brother. The Hebrews purchased their wives, by paying down a competent dowry for them; and a man was at liberty to marry, not only in any of the twelve tribes, but even out of them, provided it was with such nations as used circumcision.

The ancient Christian church laid several restraints upon her members in relation to marriage: such was the rule forbidding Christians to marry with infidels and heathens: another restraint related to the consanguinity and affinity prohibited in scripture: a third was, that children under age should not marry without the consent of their parents, guardians, or next relations: and another was, that there should be some parity of condition between the contracting parties. They not only condemned polygamy, but even reckoned it unlawful to marry after a divorce. The Romish church requires of the clergy perpetual abstinence from marriage; and has advanced this institution to the dignity of a sacrament.

MARROW, in anatomy, a soft oleaginous substance contained in the cavity of the bones. See **ANATOMY**, p. 147.

MARRUBIUM, in botany, a genus of the didynamia gymnospermia class. The calix is rigid, with ten streaks; and the upper lip of the corolla is bifid, linear, and erect. There are nine species; only one of them, *viz.* the vulgare, or white horehound, is a native of Britain.

MARS, in astronomy. See **ASTRONOMY**, p. 441.

MARS, among chemists, denotes iron, as being supposed to be under the influence of that planet. See **CHEMISTRY**, p. 82 and 133.

MARSEILLES, a city and port of Provence, situated on a fine bay of the Mediterranean, twenty five miles north-west of Toulon: E. long. 5° 20', N. lat. 43° 15'.

MARSHAL, in its primary signification, means an officer who has the command or care of horses; but it is now applied to officers who have very different employments, as earl marshal, knight marshal, or marshal of the king's house, &c.

MARSHAL of the king's bench, an officer who has the custody of the king's bench-prison in Southwark. This officer is obliged to give his attendance, and to take

take into his custody all persons committed by that court.

MARSHAL of the *exchequer*, an officer to whom that court commits the king's debtors.

MARSHAL of the *king's hall*, an officer who has the care of placing the household servants and strangers at table, according to their quality.

MARSHAL, or *MARESCHAL*, of France, an officer of the greatest dignity in the French armies. When two or more marshals are in the army, the eldest commands.

MARSHALLING a coat, in heraldry, is the disposal of several coats of arms belonging to distinct families, in one and the same escutcheon or shield, together with their ornaments, parts, and appurtenances.

MARSHFIELD, a market-town of Wiltshire, thirty-miles north-west of Salisbury.

MARSHMALLOWS, in botany. See *ALTHEA*.

MARSILEA, in botany, a genus of the cryptogamia class. The antheræ are four, and placed on an obtuse-conic body: the fruit is of a roundish figure, consisting of four cells, in each of which are contained several roundish seeds. There are two species, none of them natives of Britain.

St MARTHA, a city and port-town of Terra Firma, in South America, and the capital of the province of St Martha: W. long. $74^{\circ} 30'$, N. lat. $11^{\circ} 45'$.

MARTIAL LAW, is the law of war, which entirely depends on the arbitrary power of the prince, or of those to whom he has delegated it. For though the king can make no laws in time of peace without the consent of parliament, yet in time of war he uses an absolute power over the army.

MARTIN, in zoology. See *MUSTELA*.

Cape MARTIN, a promontory of Valencia, in Spain, on the Mediterranean: it is under the meridian of London: N. lat. $38^{\circ} 50'$.

MARTINGALE, in the manege, a thong of leather, fastened to one end of the girths under the belly of a horse, and at the other end to the muf-roll, to keep him from rearing.

MARTINICO, the chief of the French Caribbee-islands, situated in 61° of west long. and between 14° and 15° N. lat. It is sixty miles long, but is scarce twenty broad in any part.

MARTLETS, in heraldry, little birds represented without feet, and used as a difference or mark of distinction for younger brothers, to put them in mind that they are to trust to the wings of virtue and merit, in order to raise themselves, and not their feet, they having little land to set their foot on. See Plate CX fig. 2.

MARTYNIA, in botany, a genus of the didynamia angiospermia class. The calix consists of five segments; the corolla is ringent; and the capsule is woody, with a hooked beak, two valves, and three cells. There are two species, both natives of America.

MARTYR, is one who lays down his life or suffers death for the sake of his religion.

MARTYROLOGY, is a catalogue or list of martyrs, including the history of their lives and sufferings for the sake of religion.

The martyrologies draw their materials from the kalendars of particular churches, in which the several festivals dedicated to them are marked; and which seem to be derived from the practice of the ancient Romans, who inserted the names of heroes and great men in their fasti, or public registers.

The martyrologies are very numerous, and contain many ridiculous and even contradictory narratives; which is easily accounted for, if we consider how many forged and spurious accounts of the lives of saints and martyrs appeared in the first ages of the church, which the legendary writers afterwards adopted without examining into the truth of them. However, some good critics, of late years, have gone a great way towards clearing the lives of the saints and martyrs from the monstrous heap of fiction they laboured under.

MARVEL of Peru, in botany. See *MIRABILIS*.

MARY MAGDALEN'S DAY, a festival of the Romish church, observed on the twenty-second of July.

MARYGOLD. See *CALTHA*.

Corn MARYGOLD. See *CHRYSANTHEMUM*.

French MARYGOLD, in botany. See *TAGETES*.

MARYLAND, one of the British plantations in North America, situated between 74° and 78° W. long. and between 38° and 40° N. lat.

MASCULINE, or **MASCULINE GENDER**, among grammarians, that belonging to the male. See *GRAMMAR*.

MASHAM, a market town of Yorkshire, situated twenty-four miles north-west of the city of York.

MASK. See *MASQUE*.

MASON, a person employed, under the direction of an architect, in raising of a stone-building.

Free and accepted MASONS, a very ancient society or body of men, so called, either from some extraordinary knowledge of masonry or building, which they are supposed to be masters of, or because the first founders of the society were persons of that profession. These are now very considerable, both for number and character, being found in every country in Europe, and consisting principally of persons of merit and consideration. As to antiquity, they lay claim to a standing of some thousand years. What the end of their institution is, seems still in some measure a secret; and they are said to be admitted into the fraternity by being put in possession of a great number of secrets, called the mason's word, which have been religiously kept from age to age, being never divulged.

MASONRY, in general, a branch of architecture, consisting in the art of hewing or squaring stones, and cutting them level or perpendicular, for the uses of building: but, in a more limited sense, masonry is the art of assembling and joining stones together with mortar. See *ARCHITECTURE*.

MASS, in the church of Rome, the office or prayers used at the celebration of the eucharist; or, in other words, consecrating the bread and wine into the body and blood of Christ, and offering them, so transubstantiated, as an expiatory sacrifice for the quick and the dead. As the mass is in general believed to be a representation of the passion of our blessed Saviour, so

every

every action of the priest, and every particular part of the service, is supposed to allude to the particular circumstances of his passion and death.

The general division of masses consists in high and low. The first is that sung by the choristers, and celebrated with the assistance of a deacon and sub-deacon: low masses are those in which the prayers are barely rehearsed without singing.

There are a great number of different or occasional masses in the Romish church, many of which have nothing peculiar but the name: such are the masses of the saints; that of St Mary of the snow, celebrated on the fifth of August; that of St Margaret, patroness of lying-in women; that of the feast of St John the Baptist, at which are said three masses; that of the Innocents, at which the gloria in excelsis and the hallelujah are omitted, and it being a day of mourning the altar is of a violet colour. As to ordinary masses, some are said for the dead, and it is supposed, contribute to fetch the soul out of purgatory. At these masses the altar is put in mourning, and the only decorations are a cross in the midst of six yellow wax-lights: the dress of the celebrant and the very mass-book are black: many parts of the office are omitted, and the people are dismissed without the benediction. If the mass be said for a person distinguished by his rank or virtues, it is followed with a funeral oration: they erect a chapelle ardente, that is, a representation of the deceased, with branches and tapers of yellow wax, either in the middle of the church, or near the deceased's tomb, where the priest pronounces a solemn absolution of the deceased. There are likewise private masses, said for stolen or strayed goods or cattle; for health; for travellers, &c. which go under the name of votive masses. There is still a further distinction of masses denominated from the countries in which they were used; thus the Gothic mass, or missa mosarabum, is that used among the Goths when they were masters of Spain, and which is still kept up at Toledo and Salamanca; the Ambrosian mass is that composed by St Ambrose, and used only at Milan, of which city he was bishop: the Gallic mass, used by the ancient Gauls; and the Roman mass, used by almost all the churches in the Romish communion.

MASSA, the capital of the duchy of Massa Carara, in Italy, situated between the territories of Lucca and Genoa: E. long. 10°.40', N lat 43° 55'.

MASSACHUSETT-COLONY, the principal sub-division of New-England, is bounded by New Hampshire, on the north; by the Atlantic ocean, on the east and south; and by Connecticut and New York, on the west. It is about 100 miles long, and 40 broad.

MASSALIANS, a set of enthusiasts who sprang up about the year 361, in the reign of the emperor Constantius, who maintained that men have two souls, a celestial and a diabolical, and that the latter is driven out by prayer.

MASSETER, in anatomy. See **ANATOMY**, p. 221.
MASSORA, in matters of literature, a critical work, containing remarks on the verses, words, letters, and vowel-points of the Hebrew text of the bible; a work more laborious than useful.

MAST, in naval architecture, a large timber in a ship, for sustaining the yards, fails, &c.

In large vessels there are four masts, viz the main-mast, fore-mast, mizen-mast, and bowsprit. See **SHIP-BUILDING**.

MASIER, in general, is a title of authority; as, the grand master of Malta, the master of St Lazarus, &c.

The Romans had a great many officers thus denominated; as, the master of the people, or dictator; the master of the cavalry, foot, census, &c.

MASTER of arts, is the first degree taken up in universities.

MASTERS in chancery, in ordinary, of which there are twelve, the master of the rolls being chief, are usually chosen out of the barristers of the common law, and sit in chancery, or at the rolls, as assistants to the lord chancellor and master of the rolls.

MASTER of the horse, a great officer of the crown, who orders all matters relating to the king's stables, races, breed of horses; and commands the equeries and all the other officers and tradesmen employed in the king's stables. His coaches, horses, and attendants are the king's, and bear the king's arms and livery.

MASTER of the revels, an officer who orders all things relating to the performance of plays, masks, balls, &c. at court.

MASTER of the rolls, a patent officer for life, who has the custody of the rolls of parliament and patents which pass the great-seal, and of the records of chancery, as also commissions, deeds, recognizances, which, being made of rolls of parchment, gave rise to the name.

In absence of the chancellor, he sits as judge in the court of chancery: at other times, he hears causes in the rolls-chapel, and makes orders; but all hearings before him are appealable to the chancellor.

MASTER of the wardrobe, an officer under the lord chamberlain, who has the care of the royal robes, as well as the wearing apparel, collar, george, and garter, &c. He has also the charge of all former kings and queens robes remaining in the Tower, all hangings, bedding, &c. for the king's house, the charge and delivery of velvet and scarlet allowed for liveries. He has under him a clerk of the robes, wardrobe-keeper, a yeoman, &c.

MASTER-WORT, in botany. See **IMPERATORIA**.

MASICATION, the action of chewing, or of agitating the solid parts of our food between the teeth, by means of the motion of the jaws, the tongue, and the lips, whereby it is broken into small pieces, impregnated with saliva, and so fitted for deglutition and a more easy digestion.

MASTICH, in the materia medica, a solid resin, of a pale, yellow, white colour, brought to us principally from the island of Chios, in drops or tears as it naturally forms itself in exuding from the tree, about the bigness and much in the form of a pea. It is to be chosen clear, pellucid, and of a pale yellowish colour, well scented, and brittle. We meet with a kind of cement sometimes kept in the shops under the name of mastich. It is composed of mastich, and several other ingredients, and is formed into cakes for use. This is intended for the service of the lapidaries, to fill up cracks in stones, and for other such purposes:

but is by no means to be used as mastic for any of the medicinal purposes.

Mastic is detergent, astringent, and stomachic; it is greatly recommended in inveterate coughs and against spitting of blood. It strengthens the stomach, assists digestion, and stops vomiting.

MASTIGADOUR, or **SLABBERING-BIT**, in the manege, a snaffle of iron, all smooth, and of a piece, guarded with paternosters, and composed of three halves of great rings, made into demi-ovals, of unequal bigness; the lesser being inclosed within the greater, which ought to be about half a foot high.

MASULIPATAN, a city and port-town of the hither India: E. long. 81° , and N. lat. $16^{\circ} 18'$.

MATAMAN, a country in the south-west of Africa, bounded by Benguelo, on the north; by Manomotapa, on the east; by Caffraria, on the south; and by the Atlantic ocean, on the west.

MATAPAN CAPE, in the Morea, the southmost promontory of Europe, situated in E. long. 22° , N. lat. 26° .

MATCH, a kind of rope slightly twisted, and prepared to retain fire for the uses of artillery, mines, fireworks, &c.

It is made of hempen tow, spun on the wheel like cord, but very slack; and is composed of three twills, which are afterwards again covered with tow, so that the twills do not appear: lastly, it is boiled in the lees of old wines. This, when once lighted at the end, burns on gradually and regularly, without ever going out, till the whole be consumed: the hardest and driest match is generally the best.

MATCHING, in the wine trade, the preparing vessels to preserve wines and other liquors, without their growing four or rappid. The method of doing it, is as follows: melt brimstone in an iron ladle, and when thoroughly melted, dip into it slips of coarse linen-cloth; take these out, and let them cool: this the wine coopers call a match; take one of these matches, set one end of it on fire, and put it into the bung-hole of a cask; stop it loosely, and thus suffer the match to burn nearly out: then drive in the bung tight, and set the cask aside for an hour or two. At the end of this time examine the cask, and you will find that the sulphur has communicated a violent pungent and suffocating scent to the cask, with a considerable degree of acuity, which is the gas and acid spirit of the sulphur. The cask may after this be filled with a small wine, which has scarce done its fermentation; and bunging it down tight, it will be kept good, and will soon clarify: this is a common and very useful method; for many poor wines could scarce be kept potable even a few months without it.

Dura MATER. See *ANATOMY*, p. 284.

Pia MATER. See *ANATOMY*, p. 285.

MATERAN, the capital of a kingdom of the same name, situated on the south coast of the island of Java. This city is said to lie in E. long. 110° , S. lat. $7^{\circ} 45'$.

MATERIA SUBTILIS, denotes a fine subtle matter, which the Cartesians suppose to pervade and penetrate freely the pores of all bodies, to fill up all their pores so as not to leave the least vacuity or interstice between them: they have recourse to this machine to support

the doctrine of an absolute plenum, and to make it consistent with the phenomenon of motion, &c.

MATERIA MEDICA, comprehends all the substances either used in medicine in their natural state, or which afford preparations that are so; these belong partly to the animal, partly to the vegetable, and partly to the fossil kingdom.

The preparations and virtues of all which are delivered under their respective articles, but in as concise and scrupulous a manner as we possibly could; since we cannot but remark, that it is too frequent in writers on the materia medica, to give us rather encomiums than impartial accounts of the simples they treat of.

MATHEMATICS, originally signified any discipline or learning; but, at present, denotes that science which teaches, or contemplates, whatever is capable of being numbered or measured, in so far as computable or measurable; and accordingly is subdivided into Arithmetic, which has numbers for its object, and Geometry, which treats of magnitude. See *ARITHMETICK* and *GEOMETRY*.

Mathematics are commonly distinguished into pure and speculative, which consider quantity abstractedly; and mixed, which treat of magnitude as subsisting in material bodies, and consequently are interwoven every where with physical considerations.

Mixed mathematics are very comprehensive; since to them may be referred Astronomy, Optics, Geography, Hydrostatics, Mechanics, Fortification, Navigation, &c. See the articles *ASTRONOMY*, *OPTICS*, &c.

Pure mathematics have one peculiar advantage, that they occasion no disputes among wrangling disputants, as in other branches of knowledge; and the reason is, because the definitions of the terms are premised, and every body that reads a proposition has the same idea of every part of it. Hence it is easy to put an end to all mathematical controversies, by shewing, either that our adversary has not stuck to his definitions, or has not laid down true premises, or else that he has drawn false conclusions from true principles; and in case we are able to do neither of these, we must acknowledge the truth of what he has proved.

It is true, that in mixed mathematics, where we reason mathematically upon physical subjects, we cannot give such just definitions as the geometers: we must therefore rest content with descriptions; and they will be of the same use as definitions, provided we are consistent with ourselves, and always mean the same thing by those terms we have once explained.

Dr. Barrow gives a most elegant description of the excellence and usefulness of mathematical knowledge, in his inaugural oration, upon being appointed professor of mathematics at Cambridge.

The mathematics, he observes, effectually exercise, not vainly delude, nor vexatiously torment, studious minds with obscure subtilties; but plainly demonstrate every thing within their reach, draw certain conclusions, instruct by profitable rules, and unfold pleasant questions. These disciplines likewise enure and corroborate the mind to a constant diligence in study; they wholly deliver us from a credulous simplicity, most strongly fortify us against the vanity of scepticism, effectual

frequently refrain us from a rash presumption, most easily incline us to a due assent, perfectly subject us to the government of right reason. While the mind is abstracted and elevated from sensible matter, distinctly views pure forms, conceives the beauty of ideas, and investigates the harmony of proportions; the manners themselves are sensibly corrected and improved, the affections composed and rectified, the fancy calmed and settled, and the understanding raised and excited to more divine contemplations.

MATRASS, CUCURBIT, or BOLT-HEAD, among chemists. See **CHEMISTRY**, p. 109.

MATRICARIA, in botany, a genus of the *Syngenesia* polygamia superflua class. The receptacle is naked; it has, no pappus; the calix is hemispherical, and imbricated, with sharp solid margins. There are five species, all of them natives of Britain, *viz.* The parthonium, or feverfew, which is reckoned good in hysterical cases; the chamomilla, or corn-feverfew, the flowers of which are stomatick; the suaveolens, or sweet-scented feverfew; the inodora, or field feverfew; and the maritima, or sea-feverfew.

MATRICULA, a register-kept of the admission of officers and persons entered into any body or society, whereof a list is made.

MATRIX, in anatomy. See **ANATOMY**, p. 274.

MATRONALIA, a festival of the ancient Roman matrons, from whom it had its name. It was celebrated on the kalends of March in honour of the god Mars: and was to the Roman ladies what the festival of the Saturnalia was to their husbands; for at this time they served their women slaves at tables, and received presents from their husbands. See **SATURNALIA**.

MATROSSES, are soldiers in the train of artillery, who are next to the gunners, and assist them in loading, firing, and sponging the great guns. They carry firelocks, and march along with the store-waggons, both as a guard, and to give their assistance in case a waggon should break down.

MATT, in a ship, rope-yard, junk, &c. beat flat and interwoven; used in order to preserve the yards from galling or rubbing in hoisting or lowering them.

MATTER, whatever is extended and capable of making resistance: hence, because all bodies, whether solid or fluid, are extended, and do resist, we conclude that they are material, or made up of matter. See **MECHANICS**.

MATTHEW, or *Gospel of St. MATTHEW*, a canonical book of the New Testament.

St. Matthew wrote his gospel in Judea, at the request of those he had converted; and it is thought he began it in the year 41, eight years after Christ's resurrection. It was written, according to the testimony of all the ancients, in the Hebrew or Syriac language, which was then common in Judea; but the Greek version of it, which now passes for the original, it as old as the apostolical times.

St. MATTHEW the Evangelist's day, a festival of the Christian church, observed on September 21.

St. MATTHEW, in geography, a small island on the

coast of Guinea, planted by the Portuguese, but deserted: W. long. 9°, S. lat. 2° 30'.

St. MATTHIAS's day, a festival of the Christian church, observed on the 24th of February.

MATTINS, the first canonical hour, or the first part of the daily service, in the Romish church.

MATTURANTS, in pharmacy, medicines which promote the suppuration of tumours.

MAUNCH, in heraldry, the figure of an ancient coat-sleeve, borne in many gentlemen's escutcheons.

MAUNDY THURSDAY, is the Thursday in Passion-week, which was called Maunday or Mandate-thursday, from the command which our Saviour gave his apostles to commemorate him in the Lord's supper, which he this day instituted; or from the new commandment which he gave them to love one another, after he had washed their feet as a token of his love to them.

St. MAURA, an island of the Mediterranean, situated between the province of Epirus, and the island of Cephalonia; subject to Venice: E. long. 21°, N. lat. 38° 50'.

MAURICE, or **MORITUS**, an island in the Indian ocean, subject to the Dutch: E. long. 55°, S. lat. 20°.

MAURIENNE. *St. JOHN*, the capital of the territory of Maurienne, in Savoy: E. long. 6° 10', N. lat. 45° 18'.

MAURITANIA, the ancient name of the coast of Barbary, from the city of Tangier to that of Algiers: the west part of it, in which Tangier stands, was called Mauritania Tingitana; and that farther east, Mauritania Cæsariensis.

MAUSOLEUM, a magnificent tomb, or funeral monument. The word is derived from Mausolus, king of Caria, to whom Artemisia, his widow, erected a most stately monument, esteemed one of the wonders of the world, and called it, from his name, Mausoleum.

St. MAWES, a port and borough town of Cornwall: situated twenty miles north of the Lizard. It sends two members to parliament.

MAXILLA, the jaws, or those parts of an animal in which the teeth are set.

MAXIM, an established proposition or principle; in which sense it denotes much the same with axiom.

MAXIMUM, in mathematics, denotes the greatest quantity attainable in any given case.

If a quantity conceived to be generated by motion, increases, or decreases, till it arrives at a certain magnitude or position, and then on the contrary grows lesser or greater, and it be required to determine the said magnitude or position, the question is called a problem de maximis et minimis.

MAY, the fifth month of the year, consisting of thirty-one days.

MAY, is also the name of a little island, in the mouth of the frith of Forth, in Scotland.

MAYENNE, a city of France, in the province of Orleanois: W. long. 45°, and N. lat. 48° 20'.

MAYO, one of the Cape Verde islands: W. long. 23°, N. lat. 15°.

MAYO, is also a county of Ireland, in the province of Connaught, having Slego on the north, and Roscommon on the south.

MAYOR,

MAYOR, the chief magistrate of a city or town, chosen annually out of the aldermen.

MAZARA, the capital of the province of the same name in Sicily, situated on the south-west coast: E. long. $12^{\circ} 30'$, N. lat. $37^{\circ} 42'$.

MEAD, an agreeable liquor, made of honey and water.

There are many receipts for making mead, of which the following is one of the best. Take four gallons of water, and as much honey as will make it bear an egg; add to this, the rind of three lemons; boil it, and scum it well as it rises. Then take it off the fire, and add the three lemons cut in pieces; pour it into a clean tub or open vessel, and let it work for three days: then scum it well, and pour off the clear part into a cask, and let it stand open till it ceases to make a hissing noise; then stop it up close, and in three months time it will be fine and fit for bottling.

If you would give it a finer flavour, take cloves, mace, and nutmeg, of each four drams; beat them small, tie the powder in a piece of cloth, and put it into the cask.

MEADOW, in its general signification, means pasture or grass-land, annually mown for hay; but it is more particularly applied to lands that are so low as to be too moist for cattle to graze upon them in winter without spoiling the sward.

MEAN, in general, denotes the middle between two extremes: thus we say, mean distance, mean proportion, &c.

MEASLES, in medicine, a cutaneous disease, attended with a fever, in which there is an appearance of eruptions that do not tend to a suppuration. See **MEDICINE**.

MEASURE, in geometry, denotes any quantity assumed as one, or unity, to which the ratio of other homogeneous or similar quantities is expressed.

MEASURE, in a legal and commercial sense, denotes a certain quantity or proportion of anything bought, sold, valued, or the like. Measures are then various, according to the various kinds and dimensions of the things measured. Hence arise lineal or longitudinal measures, for lines or lengths; square measures, for areas or superficies; and solid or cubic measures, for bodies and their capacities. All which again are very different in different countries, and in different ages, and even many of them for different commodities. Whence arise other divisions of ancient and modern measures, domestic and foreign ones, dry measures, liquid measures, &c. For the different kinds of measures, see **ARITHMETIC**, **GEOMETRY**, and the particular names of measures, as they occur in the alphabetical order.

MEASURE is also used to signify the cadence and time observed in poetry, dancing, and music, to render them regular and agreeable.

MEASURE, in music, the interval or space of time which the person who beats time takes between the rising and falling of his hand, in order to conduct the movement sometimes quicker and sometimes slower. according to the music or subject that is to be sung or played.

MEAT. See **FOOD**, **DIET**, **DRINK**, &c.

MEATH, the name of two counties in Ireland, in the province of Leinster, distinguished by the epithets East and West.

MEATUS AUDITORIUS, in anatomy. See **ANATOMY**, p. 296.

MEAUX, a city in France, twenty-four miles north-east of Paris.

MECCA, the capital of Arabia, and place of Mohammed's nativity: E. long. $43^{\circ} 30'$, N. lat. $21^{\circ} 20'$.

It is a large well-built city, in the middle of which stands the caaba, or temple.

M E C H A N I C S.

THIS term, in the common acceptation, implies no more than the nature of what is called the mechanical powers, together with the combination of these powers in the construction of machines. But as the general properties of matter and central forces are necessary in order to a thorough knowledge of mechanics, we have joined all these subjects together under the general name of *Mechanics*.

Of MATTER, and its Properties.

By the word *matter* is here meant every thing that has length, breadth, and thickness, and resists the touch.

The inherent properties of matter are solidity, inactivity, mobility, and divisibility.

The *solidity* of matter arises from its having length, breadth, thickness; and hence it is that all bodies are comprehended under some shape or other, and that every particular body hinders all others from occupying the same part of space which it possesseth. Thus, if a piece of

wood or metal be squeezed ever so hard between two plates, they cannot be brought into contact. And even water or air has this property; for if a small quantity of it be fixed between any other bodies, they cannot be brought to touch one another.

A second property of matter is *inactivity*, or *passiveness*; by which it always endeavours to continue in the state that it is in, whether of rest or motion. And therefore, if one body contains twice or thrice as much matter as another body does, it will have twice or thrice as much inactivity; that is, it will require twice or thrice as much force to give it an equal degree of motion, or to stop it after it hath been put into such a motion.

That matter can never put itself into a motion is allowed by all men. For a stone, lying on the plain surface of the earth, never removes itself from that place, nor does any one imagine it ever can. But most people are apt to believe, that all matter has a propensity to fall from a state of motion into a state of rest; because they see, that if a

stone

stone or a cannon-ball be put into ever so violent a motion, it soon stops; not considering that this stoppage is caused, 1. By the gravity or weight of the body, which sinks it to the ground in spite of the impulse; and, 2. By the resistance of the air through which it moves, and by which its velocity is retarded every moment till it falls.

A bowl moves but a short way upon a bowling-green; because the roughness and unevenness of the grassy surface soon creates friction enough to stop it. But if the green were perfectly level, and smooth, and the bowl were perfectly hard, round, and smooth, it would go a great way further; as it would have nothing but the air to resist it: if then the air were taken away, the bowl would go on without any friction, and consequently without any diminution of the velocity it had at setting out: and therefore, if the green were extended quite around the earth, the bowl would go on round and round the earth, for ever.

If the bowl were carried several miles above the earth, and there projected in a horizontal direction, with such a velocity as would make it move more than a semidiameter of the earth, in the time it would take to fall to the earth by gravity: in that case, and if there were no resisting medium in the way, the bowl would not fall to the earth at all; but would continue to circulate round it, keeping always in the same tract, and returning to the same point from which it was projected, with the same velocity as at first. In this manner the moon moves round the earth, although she be as unactive and dead as any stone upon it.

The third property of matter is *mobility*; for we find that all matter is capable of being moved, if a sufficient degree of force be applied to overcome its inactivity or resistance.

The fourth property of matter is *divisibility*, of which there can be no end. For since matter can never be annihilated by cutting or breaking, we can never imagine it to be cut into such small particles, but that if one of them be laid on a table, the uppermost side of it will be further from the table than the undermost side.

Plate CV. fig. 1. That matter is infinitely divisible in a mathematical sense, is easy to be demonstrated. For, let AB be the length of a particle to be divided; and let it be touched at opposite ends by the parallel lines CD and EF, which suppose to be infinitely extended beyond D and F. Set off the equal divisions BG, GH, HI, &c. on the line EF, towards the right hand from B; and take a point, as at R, any where towards the left hand from A, in the line CD: Then, from this point draw the right lines RG, RH, RI, &c. each of which will cut off a part from the particle AB. But after any finite number of such lines are drawn, there will still remain a part, as AP, at the top of the particle, which can never be cut off: because the lines DR and EF being parallel, no line can ever be drawn from the point R to any point of the line EF that will coincide with the line RD. Therefore the particle AB contains more than any finite number of parts.

A fifth property of matter is *attraction*, which seems rather to be infused than inherent. Of this there are four kinds, viz. *cohesion*, *gravitation*, *magnetism*, and *electricity*.

The *attraction of cohesion* is that by which the small parts of matter are made to stick and cohere together. Of this we have several instances, some of which follow.

1. If a small glass tube, open at both ends, be dip't in water, the water will rise up in the tube to a considerable height above its level in the basin: which must be owing to the attraction of a ring of particles of the glass all around in the tube, immediately above those to which the water at any instant rises. And when it has risen so high, that the weight of the column balances the attraction of the tube, it rises no higher. This can be no ways owing to the pressure of the air upon the water in the basin; for, as the tube is open at top, it is full of air above the water, which will press as much upon the water in the tube as the neighbouring air does upon any column of an equal diameter in the basin. Besides, if the same experiment be made in an exhausted receiver of the air-pump, there will be found no difference.

2. A piece of loaf-sugar will draw up a fluid, and a sponge will suck in water; and on the same principle sap ascends in trees.

3. If two drops of quicksilver be placed near each other, they will run together, and become one large drop.

4. If two pieces of lead be scraped clean, and pressed together with a twist, they will attract each other so strongly, as to require a force much greater than their own weight to separate them. And this cannot be owing to the pressure of the air, for the same thing will hold in an exhausted receiver.

5. If two polished plates of marble or brass be put together, with a little oil between them to fill up the pores in their surfaces, and prevent the lodgement of any air; they will cohere so strongly, even if suspended in an exhausted receiver, that the weight of the lower plate will not be able to separate it from the upper one. In putting these plates together, the one should be rubbed upon the other, as a joiner does two pieces of wood when he glues them.

6. If two pieces of cork, equal in weight, be put near each other in a basin of water, they will move equally fast toward each other, with an accelerated motion, until they meet: and then, if either of them be moved, it will draw the other after it. If two corks of unequal weights be placed near each other, they will approach with accelerated velocities inversely proportionate to their weights: that is, the lighter cork will move as much faster than the heavier, as the heavier exceeds the lighter in weight. This shews that the attraction of each cork is in direct proportion to its weight or quantity of matter.

This kind of attraction reaches but to a very small distance; for, if two drops of quicksilver be rolled in dust, they will not run together, because the particles of dust keeps them out of the sphere of each other's attraction.

Where the sphere of attraction ends, a *repulsive force* begins; thus, water repels most bodies till they are wet; and hence it is, that a small needle, if dry, swims upon water; and flies walk upon it without wetting their feet.

The repelling force of the particles of a fluid is but small; and therefore, if a fluid be divided, it easily unites again. But if glass, or any other hard substance, be
↑
broke

broke into small parts, they cannot be made to stick together again without being first wetted: the repulsion being too great to admit of a re-union.

The repelling force between water and oil is so great, that we find it almost impossible to mix them so as not to separate again. If a ball of light wood be dipt in oil, and then put into water, the water will recede so as to form a channel of some depth all around the ball.

The repulsive force of the particles of air is so great, that they can never be brought so near together by condensation as to make them stick or cohere. Hence it is, that when the weight of the incumbent atmosphere is taken off from any small quantity of air, that quantity will diffuse itself so as to occupy (in comparison) an infinitely greater portion of space than it did before.

Attraction of gravitation is that power by which distant bodies tend towards one another. Of this we have daily instances in the falling of bodies to the earth. By this power in the earth it is, that bodies, on whatever side, fall in lines perpendicular to its surface; and consequently, on opposite sides, they fall in opposite directions; all towards the centre, where the force of gravity is as it were accumulated; and by this power it is, that bodies on the earth's surface are kept to it on all sides, so that they cannot fall from it. And as it acts upon all bodies in proportion to their respective quantities of matter, without any regard to their bulks or figures, it accordingly constitutes their weight. Hence,

If two bodies which contain equal quantities of matter, were placed at ever so great a distance from one another, and then left at liberty in free space; if there were no other bodies in the universe to affect them, they would fall equally swift towards one another by the power of gravity, with velocities accelerated as they approached each other; and would meet in a point which was half way between them at first. Or, if two bodies containing unequal quantities of matter, were placed at any distance, and left in the same manner at liberty, they would fall towards one another with velocities which would be in an inverse proportion to their respective quantities of matter; and moving faster and faster in their mutual approach, would at last meet in a point as much nearer to the place from which the heavier body began to fall, than to the place from which the lighter body began to fall, as the quantity of matter in the former exceeded that in the latter.

All bodies that we know of have gravity or weight. For, that there is no such thing as positive levity, even in smoke, vapours, and fumes, is demonstrable by experiments on the air-pump: which shews, that although the smoke of a candle ascends to the top of a tall receiver, when full of air; yet upon the air's being exhausted out of the receiver, the smoke falls down to the bottom of it. So, if a piece of wood be immersed in a jar of water, the wood will rise to the top of the water, because it has a less degree of weight than its bulk of water has; but if the jar be emptied of water, the wood falls to the bottom.

As every particle of matter has its proper gravity, the effect of the whole must be in proportion to the number of the attracting particles; that is, as the quantity of matter in the whole body. This is demonstrable by experi-

ments on pendulums; for if they are of equal lengths, whatever their weights be, they vibrate in equal times. Now it is plain, that if one be double or triple the weight of another, it must require a double or triple power of gravity to make it move with the same celerity; just as it would require a double or triple force to project a bullet of twenty or thirty pound weight with the same degree of swiftness that a bullet of ten pounds would require. Hence, it is evident, that the power or force of gravity is always proportional to the quantity of matter in bodies, whatever their bulks or figures are.

Gravity also, like all other virtues or emanations which proceed or issue from a centre, decreases as the distance multiplied by itself increases: that is, a body at twice the distance of another attracts with only a fourth part of the force; at thrice the distance, with a ninth part; at four times the distance, with a sixteenth part; and so on. This too is confirmed by comparing the distance which the moon falls in a minute from a right line touching her orbit, with the distance through which heavy bodies near the earth fall in that time; and also by comparing the forces which retain Jupiter's moons in their orbits, with their respective distances from Jupiter. These forces will be explained afterwards.

The velocity which bodies near the earth acquire in descending freely by the force of gravity, is proportional to the times of their descent. For, as the power of gravity does not consist in a single impulse, but is always operating in a constant and uniform manner, it must produce equal effects in equal times; and consequently in a double or triple time, a double or triple effect; and so, by acting uniformly on the body, must accelerate its motion proportionably to the time of its descent.

To be a little more particular on this subject, let us suppose that a body begins to move with a celerity constantly and gradually increasing, in such a manner, as would carry it through a mile in a minute; at the end of this space it will have acquired such a degree of celerity, as is sufficient to carry it two miles the next minute, tho' it should then receive no new impulse from the cause by which its motion had been accelerated: but if the same accelerating cause continues, it will carry the body a mile farther; on which account, it will have run through four miles at the end of two minutes; and then it will have acquired such a degree of celerity, as is sufficient to carry it through a double space in as much more time, or eight miles in two minutes, even though the accelerating force should act upon it no more. But this force still continuing to operate in an uniform manner, will again, in an equal time, produce an equal effect; and so, by carrying it a mile further, cause it to move through five miles the third minute; for, the celerity already acquired, and the celerity still acquiring, will each have its complete effect. Hence we learn, that if the body should move one mile the first minute, it would move three the second, five the third, seven the fourth, nine the fifth, and so on in proportion.

And thus it appears, that the spaces described in successive equal parts of time, by an uniformly accelerated motion, are always as the odd numbers 1, 3, 5, 7, 9, &c.

And, consequently, the whole space are as the squares of the times, or of the last acquired velocities. For, the continued addition of the odd numbers yields the squares of all numbers from unity upwards. Thus, 1, is the first odd number, and the square of 1 is 1; 3 is the second odd number, and this added to 1 makes 4, the square of 2; 5 is the third odd number, which added to 4 makes 9, the square of 3; and so on for ever. Since, therefore, the times and velocities proceed evenly and constantly as 1, 2, 3, 4, &c. but the spaces described in each equal time are as 1, 3, 5, 7, &c. it is evident that the space described,

In 1 minute will be $1 = \text{square of } 1$

In 2 minutes $1 + 3 = 4 = \text{square of } 2$

In 3 minutes $1 + 3 + 5 = 9 = \text{square of } 3$

In 4 minutes $1 + 3 + 5 + 7 = 16 = \text{square of } 4$ &c.

As heavy bodies are uniformly accelerated by the power of gravity in their descent, it is plain that they must be uniformly retarded by the same power in their ascent. Therefore, the velocity which a body acquires by falling, is sufficient to carry it up again to the same height from whence it fell; allowance being made for the resistance of the air, or other medium in which the body is moved. Thus, the body D (fig. 2.) in rolling down the inclined plane AB, will acquire such a velocity by the time it arrives at B, as will carry it up to the inclined plane BC, almost to C; and would carry it quite up to C, if the body and plane were perfectly smooth, and the air gave no resistance.—So, if a pendulum were put into motion in a space quite void of air and all other resistance, and had no friction on the point of suspension, it would move for ever; for the velocity it had acquired in falling through the descending part of the arc, would be still sufficient to carry it equally high in the ascending part thereof.

The *centre of gravity* is that point of a body in which the whole force of its gravity or weight is united. Therefore, whatever supports that point bears the weight of the whole body: and whilst it is supported, the body cannot fall, because all its parts are in a perfect equilibrium about that point.

An imaginary line drawn from the centre of gravity of any body towards the centre of the earth, is called the *line of direction*. In this line all heavy bodies descend, if not obstructed.

Since the whole weight of a body is united in its centre of gravity, as that centre ascends or descends we must look upon the whole body to do so too. But as it is contrary to the nature of heavy bodies to ascend of their own accord, or not to descend when they are permitted; we may be sure that, unless the centre of gravity be supported, the whole body will tumble or fall. Hence it is, that bodies stand upon their bases when the line of direction falls within the base; for in this case the body can not be made to fall without first raising the centre of gravity higher than it was before. Thus, the inclining body ABCD, (fig. 3.) whose centre of gravity is E, stands firmly on its base CDIK, because the line of direction EF falls within the base. But if a weight, as ABGH, be laid upon the top of the body, the centre of gravity of the whole body and weight together is raised up to I; and

and then, as the line of direction ID falls without the base at D, the centre of gravity I is not supported; and the whole body and weight tumble down together.

The broader the base is, and the nearer the line of direction is to the middle or centre of it, the more firmly does the body stand. On the contrary, the narrower the base, and the nearer the line of direction is to the side of it, the more easily may the body be overthrown: a less change of position being sufficient to remove the line of direction out of the base in the latter case than in the former. And hence it is, that a sphere is so easily rolled upon a horizontal plane; and that it is so difficult, if not impossible, to make things which are sharp pointed to stand upright on the point.—From what hath been said, it plainly appears, that if the plane be inclined on which the heavy body is placed, the body will slide down upon the plane whilst the line of direction falls within the base; but it will tumble or roll down when that line falls without the base. Thus, the body A (fig. 4.) will only slide down the inclined plane CD, whilst the body B rolls down upon it.

When the line of direction falls within the base of our feet, we stand; and most firmly, when it is in the middle: but when it is out of that base, we immediately fall. And it is not only pleasing, but even surprising, to reflect upon the various and unthought of methods and postures which we use, to retain this position, or to recover it when it is lost. For this purpose, we bend our body forward when we rise from a chair, or when we go up stairs: and for this purpose a man leans forward when he carries a burden on his back, and backward when he carries it on his breast, and to the right or left side as he carries it on the opposite side.

The quantity of matter in all bodies is in exact proportion to their weights, bulk for bulk. Therefore, heavy bodies are as much more dense or compact than light bodies of the same bulk, as they exceed them in weight.

All bodies are full of pores, or spaces void of matter: and in gold, which is the heaviest of all known bodies, there is perhaps a greater quantity of space than of matter. For the particles of heat and magnetism find an easy passage through the pores of gold; and even water itself has been forced through them. Besides, if we consider how easily the rays of light pass through so solid a body as glass, in all manner of directions, we shall find reason to believe that bodies are exceedingly porous.

All bodies are some way or other affected by heat; and all metallic bodies are expanded in length, breadth, and thickness thereby.—The proportion of the expansion of several metals, according to the best experiments, is nearly thus. Iron and glass as 3, steel 4, copper 4 and one eighth, brass 5, tin 6, lead 6 and one eighth. An iron rod 3 feet long is about one 70th part of an inch longer in summer than in winter.

The expansion of metals by heat, is demonstrated by the following machine, called a pyrometer. AA (fig. 5.) is a flat piece of mahogany, in which are fixed four brass studs B, C, D, L; and two pins, one at F, and the other at H. On the pin F turns the crooked index EI, and upon the pin H the straight index GK; against which a piece of watch-spring R bears gently, and so presses it

towards

towards the beginning of the scale MN, over which the point of that index moves. This scale is divided into inches and tenth parts of an inch: the first inch is marked 1000, the second 2000, and so on. A bar of metal O is laid into notches in the top of the fluds C and D; one end of the bar bearing against the adjusting screw P, and the other end against the crooked index EI, at a 20th part of its length from its centre of motion F.—Now it is plain, that however much the bar O lengthens, it will move that part of the index EI against which it bears just as far: but the crooked end of the same index, near H, being 20 times as far from the centre of motion F as the point is against which the bar bears, it will move 20 times as far as the bar lengthens. And as this crooked end bears against the index GK at only a 20th part of its whole length GS from its centre of motion H, the point S will move through 20 times the space that the point of bearing near H does. Hence, as 20 multiplied by 20 produces 400, it is evident, that if the bar lengthens but a 400th part of an inch, the point S will move a whole inch on the scale: and as every inch is divided into 10 equal parts, if the bar lengthens but the 10th part of the 400th part of an inch, which is only the 4000th part of an inch, the point S will move the tenth part of an inch, which is very perceptible.

To find how much a bar lengthens by heat, first lay it cold into the notches of the fluds, and turn the adjusting screw P until the spring R brings the point S of the index GK to the beginning of the divisions of the scale at M: then, without altering the screw any farther, take off the bar, and rub it with a dry woollen cloth till it feels warm: and then, laying it on where it was, observe how far it pushes the point S upon the scale by means of the crooked index EI; and the point S will shew exactly how much the bar has lengthened by the heat of rubbing. As the bar cools, the spring R bearing against the index KG, will cause its point S to move gradually back towards M in the scale: and when the bar is quite cold, the index will rest at M, where it was before the bar was made warm by rubbing. The indexes have small rollers under them at I and K; which, by turning round on the smooth wood as the indexes move, make their motions the easier, by taking off a great part of the friction, which would otherwise be on the pins F and H, and of the points of the indexes themselves on the wood.

Besides the universal properties above mentioned, there are bodies which have properties peculiar to themselves: such as the loadstone, in which the most remarkable are these, 1. It attracts iron and steel only. 2. It constantly turns one of its sides to the north and another to the south, when suspended by a thread that does not twist. 3. It communicates all its properties to a piece of steel when rubbed upon it, without losing any itself.

According to Dr Helsham's experiments, the attraction of the loadstone decreases as the square of the distance increases. Thus, if a loadstone be suspended at one end of a balance, and counterpoised by weights at the other end, and a flat piece of iron be placed beneath it, at the distance of four tenths of an inch, the stone will immediately descend and adhere to the iron. But if the stone be again removed to the same distance, and as many grains

be put into the scale at the other end as will exactly counterbalance the attraction, then, if the iron be brought twice as near the stone as before, that is, only two tenths parts of an inch from it, there must be four times as many grains put into the scale as before, in order to be a just counterbalance to the attractive force, or to hinder the stone from descending and adhering to the iron. So if four grains will do in the former case, there must be sixteen in the latter. But from some later experiments, made with the greatest accuracy, it is found that the force of magnetism decreases in a ratio between the reciprocal of the square and the reciprocal of the cube of the distance; approaching to the one or the other, as the magnitudes of the attracting bodies are varied.

Several bodies, particularly amber, glass, jet, sealing-wax, agate, and almost all precious stones, have a peculiar property of attracting and repelling light bodies when heated by rubbing. This is called *electrical attraction*; for the properties of which, see ELECTRICITY.

Of Central Forces.

We have already mentioned it as a necessary consequence arising from the deadness or inactivity of matter, that all bodies endeavour to continue in the state they are in, whether of rest or motion. If the body A (fig 6.) were placed in any part of free space, where nothing either draws or impels it any way, it would for ever remain in that part of space, because it could have no tendency of itself to remove any way from thence. If it receives a single impulse any way, as suppose from A towards B, it will go on in that direction; for, of itself it could never twerve from a right line, nor stop its course.—When it has gone through the space AB, and met with no resistance, its velocity will be the same at B as it was at A; and this velocity, in as much more time, will carry it through as much more space, from B to C; and so on for ever. Therefore, when we see a body in motion; we conclude that some other substance must have given it that motion; and when we see a body fall from motion to rest, we conclude that some other body or cause stops it.

As all motion is naturally rectilinear, it appears, that a bullet projected by the hand, or shot from a cannon, would for ever continue to move in the same direction it received at first, if no other power diverted its course. Therefore, when we see a body move in a curve of any kind whatever, we conclude it must be acted upon by two powers at least; one putting it in motion, and another drawing it off from the rectilinear course it would otherwise have continued to move in: and whenever that power, which bent the motion of the body from a straight line into a curve, ceases to act, the body will again move on in a straight line, touching that point of the curve in which it was when the action of that power ceased. For example, a pebble moved round in a sling ever so long a time, will fly off the moment it is set at liberty by slipping one end of the sling cord; and will go on in a line touching the circle it described before; which line would actually be a straight one, if the earth's attraction did not affect the pebble, and bring it down to the ground. This shews, that the natural tendency of the pebble, when put

put into motion, is to continue moving in a straight line, although by the force that moves the sling it be made to revolve in a circle.

The change of motion produced is in proportion to the force impressed: for the effects of natural causes are always proportionate to the force or power of those causes.

By these laws it is easy to prove that a body will describe the diagonal of a square or parallelogram, by two forces conjoined, in the same time that it would describe either of the sides by one force singly. Thus, suppose the body A (fig. 7.) to represent a ship at sea; and that it is drove by the wind, in the right line AB, with such a force as would carry it uniformly from A to B in a minute: then, suppose a stream or current of water running in the direction AD, with such a force as would carry the ship through an equal space from A to D in a minute. By these two forces, acting together at right angles to each other, the ship will describe the line AEC in a minute: which line (because the forces are equal and perpendicular to each other,) will be the diagonal of an exact square. To confirm this law by an experiment, let there be a wooden square ABCD (fig. 8.) so contrived, as to have the part BEFC made to draw out or pull into the square at pleasure. To this part let the pulley H be joined, so as to turn freely on an axis, which will be at H when the piece is pushed in, and at *b* when it is drawn out. To this part let the ends of a straight wire *k* be fixed, so as to move along with it, under the pulley: and let the ball G be made to slide easily on the wire. A thread *m* is fixed to this ball, and goes over the pulley to I; by this thread the ball may be drawn up on the wire, parallel to the side AD, when the part BEFC is pushed as far as it will go into the square. But, if this part be drawn out, it will carry the ball along with it, parallel to the bottom of the square DC. By this means, the ball G may either be drawn perpendicularly upward by pulling the thread *m*, or moved horizontally along by pulling out the part BEFC, in equal times, and through equal spaces; each power acting equally and separately upon it. But if, when the ball is at G, the upper end of the thread be tied to the pin I, in the corner A of the fixed square, and the moveable part BEFG be drawn out, the ball will then be acted upon by both the powers together: for it will be drawn up by the thread towards the top of the square, and at the same time carried with its wire *k* towards the right hand BC, moving all the while in the diagonal line L; and will be found at *g* when the sliding part is drawn out as far as it was before, which then will have caused the thread to draw up the ball to the top of the inside of the square, just as high as it was before, when drawn up singly by the thread without moving the sliding part.

If the acting forces are equal, but at oblique angles to each other, so will the sides of the parallelogram be: and the diagonal run through by the moving body will be longer or shorter, according as the obliquity is greater or smaller. Thus, if two equal forces act conjointly upon

the body A, (fig. 9.) one having a tendency to move it through the space AB in the same time that the other has a tendency to move it through an equal space AD; it will describe the diagonal AGC in the same time that either of the single forces would have caused it to describe either of the sides. If one of the forces be greater than the other, then one side of the parallelogram will be so much longer than the other. For if one force singly would carry the body through the space AE, in the same time that the other would have carried the space AD, the joint action of both will carry it in the same time through the space AHF, which is the diagonal of the oblique parallelogram ADEF.

If both forces act upon the body in such a manner, as to move it uniformly, the diagonal described will be a straight line; but if one of the forces acts in such a manner as to make the body move faster and faster as it goes forward, then the line described will be a curve. And this is the case of all bodies which are projected in rectilinear directions, and at the same time acted upon by the power of gravity, which has a constant tendency to accelerate their motions in the direction wherein it acts.

Laws of the Planetary motions.

From the uniform projectile motion of bodies in straight lines, and the universal power of gravity or attraction, arises the curvilinear motion of all the heavenly bodies. If the body A (fig. 10.) be projected along the straight line AFH in open space, where it meets with no resistance, and is not drawn aside by any power, it will go on for ever with the same velocity, and in the same direction. But if, at the same moment the projectile force is given it at A, the body S begins to attract it with a force duly adjusted*, and perpendicular to its motion at A, it will then be drawn from the straight line AFH, and forced to revolve about S in the circle ATW; in the same manner, and by the same law, that a pebble is moved round in a sling. And if, when the body is in any part of its orbit (as suppose at K) a smaller body as L, within the sphere of attraction of the body K, be projected in the right line LM, with a force duly adjusted, and perpendicular to the line of attraction LK; then, the small body L will revolve about the large body K in the orbit NO, and accompany it in its whole course round the yet larger body S. But then, the body K will no longer move in the circle ATW; for that circle will now be described by the common centre of gravity between K and L. Nay, even the great body S will not keep in the centre; for it will be the common centre of gravity between all the three bodies S, K, and L, that will remain immovable there. So, if we suppose S and K connected by a wire P that has no weight, and K and L connected by a wire *q* that has no weight, the common centre of gravity of all these three bodies will be a point in the wire P near S; which point being supported, the bodies will be all in *equilibrium* as they move round it. Though indeed, strictly speaking, the common centre of gravity of all the three bodies will not be in the wire

†

P

* To make the projectile force a just balance to the gravitating power, so as to keep the planet moving in a circle, it must give such a velocity as the planet would acquire by gravity when it had fallen through half the semidiameter of that circle.

P but when these bodies are all in a right line. Here, S may represent the sun, K the earth, and L the moon.

In order to form an idea of the curves described by two bodies revolving about their common centre of gravity, whilst they themselves with a third body are in motion round the common centre of gravity of all the three; let us first suppose E (Plate CVI. fig. 1.) to be the sun, and *e* the earth going round him with any moon; and their moving forces regulated as above. In this case, whilst the earth goes round the sun in the dotted circle RTUWX, &c. the sun will go round the circle ABD, whose centre C is the common centre of gravity between the sun and earth: the right line $\beta\delta$ representing the mutual attraction between them, by which they are as firmly connected as if they were fixed at the two ends of an iron bar strong enough to hold them. So, when the earth is at *e*, the sun will be at E; when the earth is at T, the sun will be at F; and when the earth is at *g*, the sun will be at G, &c.

Now, let us take in the moon *g* (at the top of the figure,) and suppose the earth to have no progressive motion about the sun; in which case, whilst the moon revolves about the earth in her orbit ABCD, the earth will revolve in the circle S 13, whose centre R is the common centre of gravity of the earth and moon; they being connected by the mutual attraction between them in the same manner as the earth and sun are.

But the truth is, that whilst the moon revolves about the earth, the earth is in motion about the sun; and now, the moon will cause the earth to describe an irregular curve, and not a true circle, round the sun; it being the common centre of gravity of the earth and moon that will then describe the same circle which the earth would have moved in, if it had not been attended by a moon. For, supposing the moon to describe a quarter of her progressive orbit about the earth in the time that the earth moves from *e* to *f*, it is plain that when the earth comes to *f*, the moon will be found at *r*; in which time, their common centre of gravity will have described the dotted arc R 1 T, the earth the curve R 5 *f*, and the moon the curve *g* 14 *r*. In the time that the moon describes another quarter of her orbit, the centre of gravity of the earth and moon will describe the dotted arc T 2 U, the earth the curve *f* 6 *g*, and the moon the curve *r* 15 *u*, and so on.—And thus, whilst the moon goes once round the earth in her progressive orbit, their common centre of gravity describes the regular portion of a circle R 1 T 2 U 3 V 4 W, the earth the irregular curve R 5 *f* 6 *g* 7 8 *i*, and the moon the yet more irregular curve *g* 14 *r* 15 *s* 16 *t* 17 *u*; and then, the same kind of tracks over again.

The centre of gravity of the earth and moon is 6000 miles from the earth's centre towards the moon; therefore the circle S 13 which the earth describes round that centre of gravity (in every course of the moon round her orbit) is 12000 miles in diameter. Consequently, the earth is 12000 miles nearer the sun at the time of full moon than at the time of new. [See the earth at *f* and at *h*.]

To avoid confusion in so small a figure, we have supposed the moon to go only twice and a half round the earth, in the time that the earth goes once round the sun: it

being impossible to take in all the revolutions which she makes in a year, and to give a true figure of her path, unless we should make the semidiameter of the earth's orbit at least 84 inches; and then, the proportional semidiameter of the moon's orbit would be only a quarter of an inch.

If the moon made any complete number of revolutions about the earth in the time that the earth makes one revolution about the sun, the paths of the sun and moon would return into themselves at the end of every year; and so be the same over again: but they return not into themselves in less than 19 years nearly; in which time, the earth makes nearly 19 revolutions about the sun, and the moon 235 about the earth.

If the planet A (Plate CV. fig. 10.) be attracted towards the sun, with such a force as would make it fall from A to B, in the time that the projectile impulse would have carried it from A to F, it will describe the arc AG by the combined action of these forces, in the same time that the former would have caused it to fall from A to B, or the latter have carried it from A to F. But, if the projectile force had been twice as great, that is, such as would have carried the planet from A to H, in the same time that now, by the supposition, it carries it only from A to F; the sun's attraction must then have been four times as strong as formerly, to have kept the planet in the circle ATW; that is, it must have been such as would have caused the planet to fall from A to E, which is four times the distance of A from B, in the time that the projectile force singly would have carried it from A to H, which is only twice the distance of A from F. Thus, a double projectile force will balance a quadruple power of gravity in the same circle; as appears plain by the figure, and shall soon be confirmed by an experiment.

Plate CVI. fig. 2. The whirling-table is a machine contrived for shewing experiments of this nature. AA is a strong frame of wood, B a winch or handle fixed on the axis C of the wheel D, round which is the catgut string F, which also goes round the small wheels G and K, crossing between them and the great wheel D. On the upper end of the axis of the wheel G, above the frame, is fixed the round board *d*, to which the bearer MSX may be fastened occasionally, and removed when it is not wanted. On the axis of the wheel H is fixed the bearer NTZ: and it is easy to see, that when the winch B is turned, the wheels and bearers are put into a whirling motion.

Each bearer has two wires, W, X, and Y, Z, fixed and screwed tight into them at the ends by nuts on the outside. And when these nuts are unscrewed, the wires may be drawn out in order to change the balls U and V, which slide upon the wires by means of brass loops fixed into the balls, which keep the balls up from touching the wood below them. A strong silk line goes through each ball, and is fixed to it at any length from the centre of the bearer to its end, as occasion requires, by a nut-screw at the top of the ball; the shank of the screw going into the centre of the ball and pressing the line against the under side of the hole that it goes through.—The line goes from the ball, and under a small pulley fixed in the middle of the bearer; then up through a socket in the round plate

plate (see S and T) in the middle of each bearer; then through a slit in the middle of the square top (O and P) of each tower, and, going over a small pulley on the top, comes down again the same way, and is a-l-a-l fastened to the upper end of the socket fixt in the middle of the above-mentioned round plate. These plates S and T have each four round holes near their edges for letting them slide up and down upon the wires which make the corner of each tower. The balls and plates being thus connected each by its particular line, it is plain, that if the balls be drawn outward, or towards the ends M and N of their respective bearers, the round plates S and T will be drawn up to the top of their respective towers O and P.

There are several brass weights, some of two ounces, some of three, and some of four, to be occasionally put within the towers O and P, upon the round plates S and T: each weight having a round hole in the middle of it, for going upon the sockets or axes of the plates, and is slit from the edge to the hole, for allowing it to be split over the forefaid line which comes from each ball to its respective plate.

The experiments to be made by this machine are,

1. Take away the bearer MX, and take the ivory ball *a*, to which the line or silk cord *b* is fastened at one end; and having made a loop on the other end of the cord, put the loop over a pin fixt in the centre of the board *d*. Then, turning the winch B to give the board a whirling motion, you will see that the ball does not immediately begin to move with the board; but, on account of its inactivity, it endeavours to continue in the state of rest which it was in before.—Continue turning, until the board communicates an equal degree of motion with its own to the ball; and then turning on, you will perceive that the ball will remain upon one part of the board, keeping the same velocity with it, and having no relative motion upon it, as is the case with every thing that lies loose upon the plane surface of the earth, which having the motion of the earth communicated to it, never endeavours to remove from that place. But stop the board suddenly by hand, and the ball will go on, and continue to revolve upon the board, until the friction thereof stops its motion: which shews, that matter being once put into motion, would continue to move for ever, if it met with no resistance. In like manner, if a person stands upright in a boat before it begins to move, he can stand firm; but the moment the boat sets off, he is in danger of falling towards that place which the boat departs from: because, as matter, he has no natural propensity to move. But when he acquires the motion of the boat, let it be ever so swift, if it be smooth and uniform, he will stand as upright and firm as if he was on the plain shore; and if the boat strike against any obstacle, he will fall towards that obstacle; on account of the propensity he has, as matter, to keep the motion which the boat has put him into.

2. Take away this ball, and put a longer cord to it, which may be put down through the hollow axis of the bearer MX, and wheel G. and fix a weight to the end of the cord below the machine; which weight, if left at liberty, will draw the ball from the edge of the whirling-board to its centre.

Draw off the ball a little from the centre, and turn the winch; then the ball will go round and round with the board, and will gradually fly off farther and farther from the centre, and raise up the weight below the machine: which shews that all bodies revolving in circles have a tendency to fly off from these circles, and must have some power acting upon them from the centre of motion, to keep them from flying off. Stop the machine, and the ball will continue to revolve for some time upon the board; but as the friction gradually stops its motion, the weight acting upon it will bring it nearer and nearer to the centre in every revolution, until it brings it quite thither. This shews, that if the planets met with any resistance in going round the sun, its attractive power would bring them nearer and nearer to it in every revolution, until they fell into it.

3. Take hold of the cord below the machine with one hand, and with the other throw the ball upon the round board as it were at right angles to the cord, by which means it will go round and round upon the board. Then, observing with what velocity it moves, pull the cord below the machine, which will bring the ball nearer to the centre of the board, and you will see that the nearer the ball is drawn to the centre, the faster it will revolve; as those planets which are nearest the sun revolve faster than those which are more remote; and not only go round sooner, because they describe smaller circles, but even move faster in every part of their respective circles.

Take away this ball, and apply the bearer MX, whose centre of motion is in its middle at *w*, directly over the centre of the whirling-board *d*. Then put two balls (V and U) of equal weights upon their bearing wires; and having fixed them at equal distances from their respective centres of motion *w* and *x* upon their silk cords, by the screw-nuts, put equal weights in the towers O and P. Lastly, put the catgut strings E and F upon the grooves G and H of the small wheels; which being of equal diameters, will give equal velocities to the bearers above, when the winch B is turned; and the balls U and V will fly off towards M and N, and will raise the weights in the towers at the same instant. This shews, that when bodies of equal quantities of matter revolve in equal circles with equal velocities, their centrifugal forces are equal.

5. Take away these equal balls, and, instead of them, put a ball of six ounces into the bearer MX, at a sixth part of the distance *wz* from the centre, and put a ball of one ounce into the opposite bearer, at the whole distance *xy*, which is equal to *wz* from the centre of the bearer; and fix the ball at these distances on their cords, by the screw-nuts at top; then the ball U, which is six times as heavy as the ball V, will be at only a sixth part of the distance from its centre of motion; and consequently will revolve in a circle of only a sixth part of the circumference of the circle in which V revolves. Now, let any equal weights be put into the towers, and the machine be turned by the winch; which (as the catgut string is on equal wheels below) will cause the balls to revolve in equal times; but V will move six times as fast as U, because it revolves in a circle of six times its radius; and both the weights in the towers will rise at once. This shews, that the centrifugal forces of revolving bodies, (or their

their tendencies to fly off from the circles they describe) are in direct proportion to their quantities of matter multiplied into their respective velocities, or into their distances from the centres of their respective circles. For, supposing U , which weighs 6 ounces, to be 20 inches from its centre of motion w , the weight multiplied by the distance is 12; and supposing V , which weighs only one ounce, to be 12 inches distant from its centre of motion x ; the weight \times ounce multiplied by the distance 12 inches is 12. And as they revolve in equal times, their velocities are as their distances from the centre, namely, as 1 to 6.

If these two balls be fixed at equal distances from their respective centres of motion, they will move with equal velocities; and if the tower O has 6 times as much weight put into it as the tower P has, the balls will raise their weight at the same moment. This shews, that the ball U , being six times as heavy as the ball V , has six times as much centrifugal force, in describing an equal circle with an equal velocity.

6. If bodies of equal weights revolve in equal circles with unequal velocities, their centrifugal forces are as the squares of the velocities. To prove this law by an experiment, let two balls U and V of equal weights be fixed on their cords at equal distances from their respective centres of motion w and x : and then let the catgut string E be put round the wheel K (whose circumference is only one half of the circumference of the wheel H or G) and over the pulley s to keep it tight; and let four times as much weight be put in the tower P as in the tower O . Then turn the winch B , and the ball V will revolve twice as fast as the ball U in a circle of the same diameter, because they are equidistant from the centres of the circles in which they revolve; and the weights in the towers will both rise at the same instant; which shews, that a double velocity in the same circle will exactly balance a quadruple power of attraction in the centre of the circle. For the weights in the towers may be considered as the attractive forces in the centres, acting upon the revolving balls; which, moving in equal circles, is the same thing as if they both moved in one and the same circle.

7. If bodies of equal weights revolve in unequal circles, in such a manner that the squares of the times of their going round are as the cubes of their distances from the centres of the circles they describe; their centrifugal forces are inversely as the squares of their distances from those centres. For, the catgut string remaining as in the last experiment, let the distance of the ball V from the centre x be made equal to two of the cross divisions on its bearer, and the distance of the ball U from the centre w be three and a sixth part; the balls themselves being of equal weights, and V making two revolutions by turning the winch in the time that U makes one: so that if we suppose the ball V to revolve in one moment, the ball U will revolve in two moments, the squares of which are one and four: for the square of 1 is only 1, and the square of 2 is 4; therefore the square of the period or revolution of the ball V is contained 4 times in the square of the ball U . But the distance of V is 2, the cube of which is 8; and the distance of U is $\frac{3}{2}$, the cube of which is $\frac{27}{8}$ very nearly; in which 8 is contained four

times; and therefore, the squares of the periods of V and U are to one another as the cubes of their distances from x and w , which are the centres of their respective circles. And if the weight in the tower O be four ounces, equal to the square of 2, the distance of V from the centre x ; and the weight in the tower P be 10 ounces, nearly equal to the square of $\frac{3}{2}$, the distance of U from w ; it will be found, upon turning the machine by the winch, that the balls U and V will raise their respective weights at very nearly the same instant of time. Which confirms that famous proposition of KEPLER, viz. That the squares of the periodical times of the planets round the sun are in proportion to the cubes of their distances from him; and that the sun's attraction is inversely as the square of the distance from its centre: that is, at twice the distance, his attraction is four times less; and thrice the distance, nine times less; at four times the distance, sixteen times less; and so on, to the remotest part of the system.

8. Take off the catgut string E from the great wheel D and the small wheel H , and let the string F remain upon the wheels D and G . Take away also the bearer MX from the whirling-board d , and instead thereof put the machine AB (fig. 4.) upon it, fixing this machine to the centre of the board by the pins c and d , in such a manner, that the end ef may rise above the board to an angle of 30 or 40 degrees. In the upper side of this machine there are two glass tubes a and b , close stop at both ends; and each tube is about three quarters full of water. In the tube a is a little quicksilver, which naturally falls down to the end a in the water, because it is heavier than its bulk of water; and on the tube b is a small cork which floats upon the top of the water at e , because it is lighter; and it is small enough to have liberty to rise or fall in the tube. While the board b with this machine upon it continues at rest, the quicksilver lies at the bottom of the tube a , and the cork floats on the water near the top of the tube b . But, upon turning the winch, and putting the machine in motion, the contents of each tube will fly off towards the uppermost ends (which are farthest from the centre of motion) the heaviest with the greatest force. Therefore, the quicksilver in the tube a will fly off quite to the end f , and occupy its bulk of space there, excluding the water from that place, because it is lighter than quicksilver; but the water in the tube b flying off to its higher end e , will exclude the cork from that place, and cause the cork to descend towards the lowermost end of the tube, where it will remain upon the lowest end of the water near b ; for the heavier body having the greater centrifugal force, will therefore possess the uppermost part of the tube; and the lighter body will keep between the heavier and the lowermost part.

This demonstrates the absurdity of the Cartesian doctrine of the planets moving round the sun in vortices: for, if the planet be more dense or heavy than the bulk of the vortex, it will fly off therein, farther and farther from the sun; if less dense, it will come down to the lowest part of the vortex, at the sun: and the whole vortex itself must be surrounded with something like a great wall, otherwise it would fly off, planets and all together.

But

Fig. 2.

But while gravity exists, there is no occasion for such vortexes; and when it ceases to exist, a stone thrown upwards will never return to the earth again.

9. If a body be so placed upon the whirling board of the machine (fig. 1.) that the centre of gravity of the body be directly over the centre of the board, and the board be put into ever so rapid a motion by the winch B, the body will turn round with the board, but will not remove from the middle of it: for, as all parts of the body are in *equilibrium* round its centre of gravity, and the centre of gravity is at rest in the centre of motion, the centrifugal force of all parts of the body will be equal at equal distances from its centre of motion; and therefore the body will remain in its place. But if the centre of gravity be placed ever so little out of the centre of motion, and the machine be turned swiftly round, the body will fly off towards that side of the board on which its centre of gravity lies. Thus, if the wire C (fig. 5.) with its little ball B be taken away from the demi-globe A, and the flat side *ef* of this demi-globe be laid upon the whirling-board of the machine, so as their centres may coincide; if then the board be turned ever so quick by the winch, the demi-globe will remain where it was placed. But if the wire C be screwed in the demi-globe at *d*, the whole becomes one body, whose centre of gravity is now at or near *d*. Let the pin *e* be fixed in the centre of the whirling-board, and the deep groove *b* cut in the flat side of the demi-globe be put upon the pin, so as the pin may be in the centre of A [See fig. 6. where this groove is represented at *b*] and let the whirling board be turned by the winch, which will carry the little ball B (fig. 5.) with its wire C, and the demi-globe A all round the centre-pin *e*; and then the centrifugal force of the little ball B, which weighs only one ounce, will be so great, as to draw off the demi-globe A, which weighs two pounds, until the end of the groove at *e* strikes against the pin *e*, and so prevents the demi-globe A from going any farther; otherwise, the centrifugal force of B would have been great enough to have carried A quite off the whirling-board. Which shews, that if the sun were placed in the very centre of the orbits of the planets, it could not possibly remain there; for the centrifugal forces of the planets would carry them quite off, and the sun with them; especially when several of them happened to be in any one quarter of the heavens. For the sun and planets are as much connected by the mutual attraction that subsists between them, as the bodies A and B are by the wire C which is fixed to them both. And even if there were but one single planet in the whole heavens to go round ever so large a sun in the centre of its orbit, its centrifugal force would soon carry off both itself and the sun. For, the greatest body placed in any part of free space could be easily moved: because if there were no other body to attract it, it could have no weight or gravity of itself; and consequently, though it could have no tendency of itself to remove from that part of space, yet it might be very easily by any other substance. And perhaps it is this consideration which made the celebrated ARCHIMEDES say, that if he had a proper place at some distance from the earth whereon to fix his machinery, he could move the whole earth.

10. As the centrifugal force of the light body B will not allow the heavy body A to remain in the centre of motion, even though it be 24 times as heavy as B; let us now take the ball A (fig. 7.) which weighs 6 ounces, and connect it by the wire C with the ball B, which weighs only one ounce; and let the fork E be fixed into the centre of the whirling-board; then, hang the balls upon the fork by the wire C in such a manner that they may exactly balance each other; which will be when the centre of gravity between them, in the wire at *d*, is supported by the fork. And this centre of gravity is as much nearer to the centre of the ball A, than to the centre of the ball B, as A is heavier than B, allowing for the weight of the wire on each side of the fork. This done, let the machine be put into motion by the winch; and the balls A and B will go round their common centre of gravity *d*, keeping their balance, because either will not allow the other to fly off with it. For, supposing the ball B to be only one ounce in weight, and the ball A to be six ounces; then, if the wire C were equally heavy on each side of the fork, the centre of gravity *d* would be six times as far from the centre of the ball B as from the centre of the ball A, and consequently B will revolve with a velocity six times as great as A does; which will give B six times as much centrifugal force as any single ounce of A has; but then, as B is only one ounce, and A six ounces, the whole centrifugal force of A will exactly balance the whole centrifugal force of B; and therefore, each body will retain the other so as to make it keep in its circle. This shews that the sun and planets must all move round the common centre of gravity of the whole system, in order to preserve that just balance which takes place among them. For, the planets being as unactive and dead as the above balls, they could no more have put themselves into motion than these balls can; nor have kept in their orbits, without being balanced at first with the greatest degree of exactness upon their common centre of gravity by the Almighty Hand that made them and put them in motion.

Perhaps it may be here asked, that since the centre of gravity between these balls must be supported by the fork E in this experiment, what prop it is that supports the centre of gravity of the solar system, and consequently bears the weight of all the bodies in it; and by what is the prop itself supported? The answer is easy and plain; for the centre of gravity of our balls must be supported, because they gravitate towards the earth, and would therefore fall to it: but as the sun and planets gravitate only towards one another, they have nothing else to fall to; and therefore have no occasion for any thing to support their common centre of gravity: and if they did not move round that centre, and consequently acquire a tendency to fly from it by their motions, their mutual attractions would soon bring them together; and so the whole would become one mass in the sun: which would also be the case if their velocities round the sun were not quick enough to create a centrifugal force equal to the sun's attraction.

But after all this nice adjustment, it appears evident, that the Deity cannot withdraw his regulating hand from his works, and leave them to be solely governed by the

laws which he has impressed upon them at first. For if he should once leave them so, their order would in time come to an end; because the planets must necessarily disturb one another's motions by their mutual attractions, when several of them are in the same quarter of the heavens; as is often the case: and then, as they attract the sun more towards that quarter than when they are in a manner dispersed equally around him, if he was not at that time made to describe a portion of a larger circle round the common centre of gravity, the balance would then be immediately destroyed; and as it could never restore itself again, the whole system would begin to fall together, and would in time unite in a mass at the sun. —Of this disturbance we have a very remarkable instance in the comet which appeared lately; and which, in going last year before the sun, went so near to Jupiter, and was so affected by his attraction, as to have the figure of its orbit much changed; and not only so, but to have its period altered, and its course to be different in the heavens from what it was last before.

11. Take away the fork and balls from the whirling-board, and place the trough AB (fig. 8.) thereon, fixing its centre to the centre of the whirling-board by the pin H. In this trough are two balls D and E, of unequal weights, connected by a wire *f*; and made to slide easily upon the wire C stretched from end to end of the trough, and made fast by nut-screws on the outside of the ends. Let these balls be so placed upon the wire C. that their common centre of gravity *g* may be directly over the centre of the whirling-board. Then, turn the machine by the winch *e* so swiftly, and the trough and balls will go round their centre of gravity so as neither of them will fly off; because, on account of the equilibrium, each ball detains the other with an equal force acting against it. But if the ball E be drawn a little more towards the end of the trough at A, it will remove the centre of gravity towards that end from the centre of motion; and then, upon turning the machine, the little ball E will fly off, and strike with a considerable force against the end A, and draw the great ball B into the middle of the trough. Or, if the great ball D be drawn towards the end B of the trough, so that the centre of gravity may be a little towards that end from the centre of motion, and the machine be turned by the winch, the great ball D will fly off, and strike violently against the end B of the trough, and will bring the little ball E into the middle of it. If the trough be not made very strong, the ball D will break through it.

12. The reason why the tides rise at the same absolute time on opposite sides of the earth, and consequently in opposite directions, is made abundantly plain by a new experiment on the whirling table. The cause of their rising on the side next the moon every one understands to be owing to the moon's attraction: but why they should rise on the opposite side at the same time, where there is no moon to attract them, is perhaps not so generally understood. For it would seem that the moon should rather draw the waters (as it were) closer to that side, than raise them upon it, directly contrary to her attractive force. Let the circle *abcd* (fig. 9.) represent the earth, with its side *c* turned toward the moon, which will then attract

the waters so as to raise them from *c* to *g*. But the question is, why should they rise as high at that very time on the opposite side, from *a* to *e*? In order to explain this, let there be a plate AB (fig. 10.) fixed upon one end of the flat bar DC; with such a circle drawn upon it as *abcd* (in fig. 9.) to represent the round figure of the earth and sea; and such an ellipsis as *efgh* to represent the swelling of the tide at *e* and *g*, occasioned by the influence of the moon. Over this plate AB let the three ivory balls *e, f, g* be hung by the silk lines *h, i, k*, fastened to the tops of the crooked wires H, I, K, in such a manner, that the ball at *e* may hang freely over the side of the circle *e*, which is farthest from the moon M (at the other end of the bar;) the ball at *f* may hang freely over the centre, and the ball at *g* hang over the side of the circle *g*, which is nearest the moon. The ball *f* may represent the centre of the earth, the ball *g* some water on the side next the moon, and the ball *e* some water on the opposite side. On the back of the moon M is fixt the short bar N parallel to the horizon, and there are three holes in it above the little weights *p, q, r*. A silk thread *o* is tied to the line *k* close above the ball *g*, and, passing by one side of the moon M, goes through a hole in the bar N, and has the weight *p* hung to it. Such another thread *n* is tied to the line *i*, close above the ball *f*, and, passing through the centre of the moon M and middle of the bar N, has the weight *q* hung to it, which is lighter than the weight *p*. A third thread *m* is tied to the line *h*, close above the ball *e*, and passing by the other side of the moon M, through the bar N, has the weight *r* hung to it, which is lighter than the weight *q*.

The use of these three unequal weights is to represent the moon's unequal attraction at different distances from her. With whatever force she attracts the centre of the earth, she attracts the side next her with a greater degree of force, and the side farthest from her with a less. So, if the weights are left at liberty, they will draw all the three balls towards the moon with different degrees of force, and cause them to make the appearance shewn in (fig. 11.) by which means they are evidently farther from each other than they would be if they hung at liberty by the lines *h, i, k*; because the lines would then hang perpendicularly. This shews, that as the moon attracts the side of the earth which is nearest her with a greater degree of force than she does the centre of the earth, she will draw the water on that side more than she draws the centre, and so causes it to rise on that side: and as she draws the centre more than she draws the opposite side, the centre will recede farther from the surface of the water on that opposite side, and so leave it as high there as she raised it on the side next to her. For, as the centre will be in the middle between the tops of the opposite elevations, they must of course be equally high on both sides at the same time.

But upon this supposition the earth and moon would soon come together; and to be sure they would, if they had not a motion round their common centre of gravity, to create a degree of centrifugal force sufficient to balance their mutual attraction. This motion they have; for as the moon goes round her orbit every month, at the

the distance of 240000 miles from the earth's centre, and of 234000 miles from the centre of gravity of the earth and moon, so does the earth go round the same centre of gravity every month at the distance of 6000 miles from it; that is, from it to the centre of the earth. Now as the earth is (in round numbers) 8000 miles in diameter, it is plain that its side next the moon is only 2000 miles from the common centre of gravity of the earth and moon; its centre 6000 miles distant therefrom; and its farthest side from the moon 10000. Therefore the centrifugal forces of these parts are as 2000, 6000, and 10000; that is, the centrifugal force of any side of the earth, when it is turned from the moon, is five times as great as when it is turned towards the moon. And as the moon's attraction (expressed by the number 6000) at the earth's centre keeps the earth from flying out of this monthly circle, it must be greater than the centrifugal force of the waters on the side next her; and consequently, her greater degree of attraction on that side is sufficient to raise them; but as her attraction on the opposite side is less than the centrifugal force of the water there, the excess of this force is sufficient to raise the water just as high on the opposite side.—To prove this experimentally, let the bar DC (fig. 10.) with its furniture be fixed upon the whirling board of the machine (fig. 2.) by pulling the pin P into the centre of the board; which pin is in the centre of gravity of the whole bar with its three balls *e*, *f*, *g*, and moon M. Now, if the whirling-board and bar be turned slowly round by the winch, until the ball *f* hangs over the centre of the circle, as in fig. 11. the ball *g* will be kept towards the moon by the heaviest weight *p*, (fig. 9.) and the ball *e*, on account of its greater centrifugal force, and the lesser weight *r*, will fly off as far to the other side as in fig. 12. And so, whilst the machine is kept turning, the balls *e* and *g* will hang over the ends of the ellipsis *l*, *f*, *k*. So that the centrifugal force of the ball *e* will exceed the moon's attraction just as much as her attraction exceeds the centrifugal force of the ball *g*, whilst her attraction just balances the centrifugal force of the ball *f*, and makes it keep in its circle. And hence it is evident that the tides must rise to equal heights at the same time on opposite sides of the earth. This experiment, to the best of my knowledge, is entirely new.

From the principles thus established, it is evident that the earth moves round the sun, and not the sun round the earth; for the centrifugal law will never allow a great body to move round a small one in any orbit whatever; especially when we find, that if a small body moves round a great one, the great one must also move round the common centre of gravity between them two. And it is well known, that the quantity of matter in the sun is 227000 times as great as the quantity of matter in the earth. Now, as the sun's distance from the earth is at least 81,000,000 of miles, if we divide that distance by 227000, we shall have only 357 for the number of miles that the centre of gravity between the sun and earth is distant from the sun's centre. And as the sun's semidiameter is $\frac{1}{2}$ of a degree, which, at so great a distance as that of the sun, must be no less than 381500 miles, if this be divided by 357, the quotient will be 1068 $\frac{3}{4}$,

which shews that the common centre of gravity is within the body of the sun, and is only the 1068 $\frac{3}{4}$ part of his semidiameter from his centre toward his surface.

All globular bodies, whose parts can yield, and which do not turn on their axes, must be perfect spheres, because all parts of their surfaces are equally attracted toward their centres. But all such globes which do turn on their axes, will be oblate spheroids; that is, their surfaces will be higher, or farther from the centre, in the equatorial than in the polar regions. For, as the equatorial parts move quickest, they must have the greatest centrifugal force; and will therefore recede farthest from the axis of motion. Thus, if two circular hoops AB and CD, (Plate CVII. fig. 1.) made thin and flexible, and crossing one another at right angles, be turned round their axis EF by means of the winch *m*, the wheel *n*, and pinion *o*, and the axis be loose in the pole or intersection *e*, the middle parts A,B,C,D will swell out so as to strike against the sides of the frame at F and G, if the pole *e*, in sinking to the pin E, be not flopped by it from sinking farther: so that the whole will appear of an oval figure, the equatorial diameter being considerably longer than the polar. That our earth is of this figure, is demonstrable from actual measurement of some degrees on its surface, which are found to be longer in the frigid zones than in the torrid: and the difference is found to be such as prove the earth's equatorial diameter to be 35 miles longer than its axis.—Since then, the earth is higher at the equator than at the poles, the sea, which like all other fluids naturally runs downward (or towards the places which are nearest the earth's centre) would run towards the polar regions, and leave the equatorial parts dry, if the centrifugal force of the water, which carried it to those parts, and so raised them, did not detain and keep it from running back again towards the poles of the earth.

Of the Mechanical Powers.

If we consider bodies in motion, and compare them together. We may do this either with respect to the quantities of matter they contain, or the velocities with which they are moved. The heavier any body is, the greater is the power required either to move it or to stop its motion: and again, the swifter it moves, the greater is its force. So that the whole *momentum* or quantity of force of a moving body is the result of its quantity of matter multiplied by the velocity with which it is moved. And when the products arising from the multiplication of the particular quantities of matter in any two bodies by their respective velocities are equal, the *momenta* or entire forces are so too. Thus, suppose a body, which we shall call A, to weigh 40 pounds, and to move at the rate of two miles in a minute; and another body, which we shall call B, to weigh only four pounds, and to move 20 miles in a minute; the entire forces with which these two bodies would strike against any obstacle would be equal to each other, and therefore it would require equal powers to stop them. For 40 multiplied by 2 gives 80, the force of the body A; and 20 multiplied by 4 gives 80, the force of the body B.

Upon this easy principle depends the whole of mechanics:

chanics: and it holds universally true, that when two bodies are suspended by any machine, so as to act contrary to each other: if the machine be put into motion, and the perpendicular ascent of one body multiplied into its weight, be equal to the perpendicular descent of the other body multiplied into its weight, these bodies, how unequal soever in their weights, will balance one another in all situations: for, as the whole ascent of one is performed in the same time with the whole descent of the other, their respective velocities must be directly as the spaces they move through; and the excess of weight in one body is compensated by the excess of velocity in the other.—Upon this principle, it is easy to compute the power of any mechanical engine, whether simple or compound; for it is but only inquiring how much swifter the power moves than the weight does (*i. e.* how much farther in the same time,) and just so much is the power increased by the help of the engine.

In the theory of this science, we suppose all planes perfectly even, all bodies perfectly smooth, levers to have no weight, cords to be extremely pliable, machines to have no friction; and in short, all imperfection must be set aside until the theory be established, and then proper allowances are to be made.

The simple machines, usually called *mechanical powers*, are six in number, viz. the *lever*, the *wheel and axle*, the *pulley*, the *inclined plane*, the *wedge*, and the *crew*. They are called mechanical powers, because they help us to raise weights, move heavy bodies, and overcome resistances, which we could not effect without them.

1. A *lever* is a bar of iron or wood, one part of which being supported by a prop, all the other parts turn upon that prop as their centre of motion: and the velocity of every part or point is directly as its distance from the prop. Therefore, when the weight to be raised at one end is to the power applied at the other to raise it, as the distance of the power from the prop is to the distance of the weight from the prop, the power and weight will exactly balance or counterpoise each other: and as a common lever has but very little friction on its prop, a very little additional power will be sufficient to raise the weight.

There are four kinds of levers. 1. The common sort, where the prop is placed between the weight and the power; but much nearer to the weight than to the power. 2. When the prop is at one end of the lever, the power at the other, and the weight between them. 3. When the prop is at one end, the weight at the other, and the power applied between them. 4. The bended lever, which differs only in form from the first sort, but not in property. Those of the first and second kind are often used in mechanical engines; but there are few instances in which the third sort is used.

A *common balance* is a lever of the first kind; but as both its ends are at equal distances from its centre of motion, they move with equal velocities; and therefore, as it gives no mechanical advantage, it cannot properly be reckoned among the mechanical powers.

A lever of the first kind is represented by the bar ABC, (Plate CVII. fig. 2.) supported by the prop D. Its principal use is to loosen large stones in the ground, or raise great weights to small heights, in order to have

ropes put under them for raising them higher by other machines. The parts AB and BC, on different sides of the prop D, are called the arms of the lever: the end A of the shorter arm AB being applied to the weight intended to be raised, or to the resistance to be overcome, and the power applied to the end C of the longer arm BC.

In making experiments with this machine, the shorter arm AB must be as much thicker than the longer arm BC, as will be sufficient to balance it on the prop. This supposed, let P represent a power whose intensity is equal to one ounce, and W a weight whose intensity is equal to 12 ounces. Then, if the power be 12 times as far from the prop as the weight is, they will exactly counterpoise; and a small addition to the power P will cause it to descend, and raise the weight W; and the velocity with which the power descends will be to the velocity with which the weight rises, as 12 to 1: that is, directly as their distances from the prop; and consequently, as the spaces through which they move. Hence it is plain, that a man who by his natural strength, without the help of any machine, could support an hundred weight, will by the help of this lever be enabled to support twelve hundred. If the weight be less, or the power greater, the prop may be placed so much the farther from the weight; and then it can be raised to a proportionably greater height. For universally, if the intensity of the weight multiplied into its distance from the prop be equal to the intensity of the power multiplied into its distance from the prop, the power and weight will exactly balance each other; and a little addition to the power will raise the weight. Thus, in the present instance, the weight W is 12 ounces, and its distance from the prop is 1 inch; and 12 multiplied by 1 is 12; the power P is equal to 1 ounce, and its distance from the prop is 12 inches, which multiplied by one is 12 again; and therefore there is an equilibrium between them. So, if a power equal to 2 ounces be applied at the distance of 6 inches from the prop, it will just balance the weight W; for 6 multiplied by 2 is 12, as before. And a power equal to 3 ounces placed at 4 inches distance from the prop would do the same; for 3 times 4 is 12; and so on, in proportion.

The *statera*, or Roman *steelyard*, is a lever of this kind, contrived for finding the weights of different bodies by one single weight placed at different distances from the prop or centre of motion D. For, if a scale hangs at A, the extremity of the shorter arm AB, and is of such a weight as will exactly counterpoise the longer arm BC; if this arm be divided into as many equal parts as it will contain, each equal to AB, the single weight P (which we may suppose to be 1 pound) will serve for weighing any thing as heavy as itself, or as many times heavier as there are divisions in the arm BC, or any quantity between its own weight and that quantity. As for example, if P be 1 pound, and placed at the first division 1 in the arm BC, it will balance 1 pound in the scale at A: if it be removed to the second division at 2, it will balance 2 pounds in the scale; if to the third, 3 pounds: and so on to the end of the arm BC. If each of these integral divisions be subdivided into as many equal parts as a pound contains ounces, and the weight

P be placed at any of these subdivisions, so as to counterpoise what is in the scale, the pounds and odd ounces therein are by that means ascertained.

To this kind of lever may be reduced several sorts of instruments, such as scissars, pinchers, snuffers; which are made of two levers acting contrary to one another; their prop or centre of motion being the pin which keeps them together.

In common practice, the longer arm of this lever greatly exceeds the weight of the shorter; which gains great advantage, because it adds so much to the power.

A lever of the second kind has the weight between the prop and the power. In this, as well as the former, the advantage gained is as the distance of the power from the prop to the distance of the weight from the prop: for the respective velocities of the power and weight are in that proportion; and they will balance each other when the intensity of the power multiplied by its distance from the prop is equal to the intensity of the weight multiplied by its distance from the prop. Thus, if AB (fig. 3.) be a lever on which the weight W of 6 ounces hangs at the distance of 1 inch from the prop G, and a power P equal to the weight of one ounce hangs at the end B, 6 inches from the prop, by the cord CD going over the fixed pulley E, the power will just support the weight; and a small addition to the power will raise the weight 1 inch for every 6 inches that the power descends.

This lever shews the reason why two men carrying a burden upon a stick between them, bear unequal shares of the burden in the inverse proportion of their distances from it. For it is well known, that the nearer any of them is to the burden, the greater share he bears of it: and if he goes directly under it, he bears the whole. So, if one man be at G, and the other at P, having the pole or stick AB resting on their shoulders; if the burden or weight W be placed five times as near the man at G, as it is to the man at P, the former will bear five times as much weight as the latter. This is likewise applicable to the case of two horses of unequal strength, to be so yoked, as that each horse may draw a part proportionable to his strength; which is done by dividing the beam so, that the point of traction may be as much nearer to the stronger horse than to the weaker, as the strength of the former exceeds that of the latter.

To this kind of lever may be reduced oars, rudders of ships, doors turning upon hinges, cutting knives which are fixed at the point of the blade, and the like.

If in this lever we suppose the power and weight to change places, so that the power may be between the weight and the prop, it will become a lever of the third kind; in which, that there may be a balance between the power and the weight, the intensity of the power must exceed the intensity of the weight, just as much as the distance of the weight from the prop exceeds the distance of the power from it. Thus, let E (fig. 4.) be the prop of the lever AB, and W a weight of 1 pound, placed 3 times as far from the prop, as the power P acts at F, by the cord C going over the fixed pulley D; in this case, the power must be equal to three pounds, in order to support the weight.

To this sort of lever are generally referred the bones of a man's arm: for when we lift a weight by the hand, the muscle that exerts its force to raise that weight, is fixed to the bone about one tenth part as far below the elbow as the hand is. And the elbow being the centre round which the lower part of the arm turns, the muscle must therefore exert a force ten times as great as the weight that is raised.

As this kind of lever is a disadvantage to the moving power, it is never used but in cases of necessity; such as that of a ladder, which, being fixed at one end, is by the strength of a man's arms reared against a wall; and in clock-work, where all the wheels may be reckoned levers of this kind, because the power that moves every wheel, except the first, acts upon it near the centre of motion by means of a small pinion, and the resistance it has to overcome acts against the teeth round its circumference.

The fourth kind of lever differs nothing from the first, but in being bended for the sake of convenience. ACB (fig. 5.) is a lever of this sort, bended at C, which is its prop, or centre of motion. P is a power acting upon the longer arm AC at F, by means of the cord DE going over the pulley G; and W is a weight or resistance acting upon the end B of the shorter arm BC. If the power be to the weight as BC is to CF, they are in *equilibrio*. Thus, suppose W to be 5 pounds acting at the distance of one foot from the centre of motion C, and P to be 1 pound acting at F, five feet from the centre C, the power and weight will just balance each other. A hammer drawing a nail is a lever of this sort.

2. The second mechanical power is the *wheel and axle*, in which the power is applied to the circumference of the wheel, and the weight is raised by a rope which coils about the axle as the wheel is turned round. Here it is plain, that the velocity of the power must be to the velocity of the weight, as the circumference of the wheel is to the circumference of the axle: and consequently, the power and weight will balance each other, when the intensity of the power is to the intensity of the weight as the circumference of the axle is to the circumference of the wheel. Let AB (fig. 6.) be a wheel, CD its axle, and suppose the circumference of the wheel to be 8 times as great as the circumference of the axle; then a power P equal to 1 pound hanging by the cord I, which goes round the wheel, will balance a weight W of 8 pounds hanging by the rope K which goes round the axle. And as the friction on the pivots or gudgeons of the axle is but small, a small addition to the power will cause it to descend, and raise the weight: but the weight will rise with only an eighth part of the velocity wherewith the power descends, and consequently through no more than an eighth part of an equal space, in the same time. If the wheel be pulled round by the handles S, S, the power will be increased in proportion to their length. And by this means, any weight may be raised as high as the operator pleases.

To this sort of engine belong all cranes for raising great weights; and in this case, the wheel may have cogs all around it instead of handles, and a small lantern or trundle may be made to work in the cogs, and be turned

by a winch; which will make the power of the engine to exceed the power of the man who works it, as much as the number of revolutions of the winch exceed those of the axle D, when multiplied by the excess of the length of the winch above the length of the semidiameter of the axle, added to the semidiameter or half thickness of the rope K, by which the weight is drawn up. Thus, suppose the diameter of the rope and axle taken together to be 12 inches, and consequently half their diameters to be 6 inches; so that the weight W will hang at 6 inches perpendicular distance from below the centre of the axle. Now, let us suppose the wheel AB, which is fixt on the axle, to have 80 cogs, and to be turned by means of a winch six inches long, fixt on the axis of a trundle of 8 staves or rounds, working in the cogs of the wheel.—Here it is plain, that the winch and trundle would make 10 revolutions for one of the wheel AB, and its axis D, on which the rope K winds in raising the weight W; and the winch being no longer than the sum of the semi diameters of the great axle and rope, the trundle could have no more power on the wheel, than a man could have by pulling it round by the edge, because the winch would have no greater velocity than the edge of the wheel has, which we here suppose to be ten times as great as the velocity of the rising weight; so that, in this case, the power gained would be as 10 to 1. But if the length of the winch be 12 inches, the power gained will be as 20 to 1: if 18 inches (which is long enough for any man to work by) the power gained would be as 30 to 1; that is, a man could raise 30 times as much by such an engine, as he could do by his natural strength without it, because the velocity of the handle of the winch would be 30 times as great as the velocity of the rising weight; the absolute force of any engine being in proportion of the velocity of the power to the velocity of the weight raised by it.—But then, just as much power or advantage as is gained by the engine, so much time is lost in working it. In this sort of machines it is requisite to have a ratchet-wheel G on one end of the axle, with a catch H to fall into its teeth; which will at any time support the weight, and keep it from descending; if the workman should, through inadvertency or carelessness, quit his hold whilst the weight is raising. And by this means, the danger is prevented which might otherwise happen by the running down of the weight when left at liberty.

3. The third mechanical power or engine consists either of one *moveable pulley*, or a *system of pulleys*; some in a block or case which is fixed, and others in a block which is moveable, and rises with the weight. For tho' a single pulley, that only turns on its axis, and rises not with the weight, may serve to change the direction of the power, yet it can give no mechanical advantage thereto; but is only as the beam of a balance, whose arms are of equal length and weight. Thus, if the equal weights W and P (fig. 7.) hang by the cord BB upon the pulley A, whose block *b* is fixed to the beam HI, they will counterpoise each other, just in the same manner as if the cord were cut in the middle, and its two ends hung upon the hooks fixt in the pulley at A and A, equally distant from its centre.

But if a weight W hangs at the lower end of the move-

able block *p* of the pulley D, and the cord GF goes under the pulley, it is plain that the half G of the cord bears one half of the weight W, and the half F the other; for they bear the whole between them. Therefore, whatever holds the upper end of either rope, sustains one half of the weight; and if the cord at F be drawn up so as to raise the pulley D to C, the cord will then be extended to its whole length, all but that part which goes under the pulley: and consequently, the power that draws the cord will have moved twice, as far as the pulley D with its weight W rises: on which account, a power whose intensity is equal to one half of the weight will be able to support it, because if the power moves (by means of a small addition) its velocity will be double the velocity of the weight; as may be seen by putting the cord over the fixt pulley C (which only changes the direction of the power, without giving any advantage to it) and hanging on the weight P, which is equal only to one half of the weight W; in which case there will be an equilibrium, and a little addition to P will cause it to descend, and raise W through a space equal to one half of that through which P descends.—Hence, the advantage gained will be always equal to twice the number of pulleys in the moveable or undermost block. So that, when the upper or fixt block *x* contains two pulleys, which only turn on the axes, and the lower or moveable block U contains two pulleys, which not only turn upon their axes, but also rise with the block and weight; the advantage gained by this is as 4 to the working power. Thus, if one end of the rope KMOQ be fixed to a hook at I, and the rope passes over the pulleys N and R, and under the pulleys L and P, and has a weight T, of one pound, hung to its other end at T, this weight will balance and support a weight W of four pounds hanging by a hook at the moveable block U, allowing the said block as a part of the weight. And if as much more power be added as is sufficient to overcome the friction of the pulleys, the power will descend with four times as much velocity as the weight rises, and consequently through four times as much space.

The two pulleys in the fixed block X, and the two in the moveable block Y, are in the same case with those last mentioned; and those in the lower block give the same advantage to the power.

As a system of pulleys has not great weight and lies in a small compass, it is easily carried about: and can be applied, in a great many cases, for raising weights, where other engines cannot. But they have a great deal of friction, on three accounts: 1. Because the diameters of their axes bear a very considerable proportion to their own diameters; 2. Because in working they are apt to rub against one another, or against the sides of the block; 3. Because of the stiffness of the rope that goes over and under them.

4. The fourth mechanical power is the *inclined plane*; and the advantage gained by it is as great as its length exceeds its perpendicular height. Let AB (fig. 8.) be a plane parallel to the horizon, and CD a plane inclined to it; and suppose the whole length CD to be three times as great as the perpendicular height G/F: in this case, the cylinder E will be supported upon the plane CD, and

kept

kept from rolling down upon it, by a power equal to a third part of the weight of the cylinder. Therefore, a weight may be rolled up this inclined plane with a third part of the power which would be sufficient to draw it up by the side of an upright wall. If the plane was four times as long as high, a fourth part of the power would be sufficient; and so on, in proportion. Or, if a pillar was to be raised from a floor to the height GF, by means of the engine ABCD, (which would then act as a half wedge, where the resistance gives way only on one side) the engine and pillar would be in *equilibrium* when the power applied at GF was to the weight of the pillar as GF to GD; and if the power be increased, so as to overcome the friction of the engine against the floor and pillar, the engine will be driven, and the pillar raised: and when the engine has moved its whole length upon the floor, the pillar will be raised to the whole height of the engine, from G to F.

The force wherewith a rolling body descends upon an inclined plane, is to the force of its absolute gravity, by which it would descend perpendicularly in a free space, as the height of the plane is to its length. For, suppose the plane AB (fig. 9.) to be parallel to the horizon, the cylinder C will keep at rest upon any part of the plane where it is laid. If the plane be so elevated, that its perpendicular height D (fig. 10.) is equal to half its length AB, the cylinder will roll down upon the plane with a force equal to half its weight; for it would require a power (acting on the direction of AB) equal to half its weight, to keep it from rolling. If the plane AB (fig. 11.) be elevated, so as to be perpendicular to the horizon, the cylinder C will descend with its whole force of gravity, because the plane contrains nothing to its support or hindrance; and therefore, it would require a power equal to its whole weight to keep it from descending.

Let the cylinder C (fig. 12.) be made to turn upon slender pivots in the frame D, in which there is a hook *e*, with a line G tied to it: let this line go over the fixed pulley H, and have its other end tied to a hook in the weight I. If the weight of the body I, be to the weight of the cylinder C, added to that of its frame D, as the perpendicular height of the plane LM is to its length AB, the weight will just support the cylinder upon the plane, and a small touch of a finger will either cause it to ascend or descend with equal ease: then, if a little addition be made to the weight I, it will descend, and draw the cylinder up the plane. In the time that the cylinder moves from A to B, it will rise through the whole height of the plane ML; and the weight will descend from H to K, through a space equal to the whole length of the plane AB.

If the plane be made to move upon rollers or friction-wheels, and the cylinder be supported upon it: the same power will draw the plane under the cylinder, which before drew the cylinder up the plane, provided the pivots of the axes of the friction-wheels be small, and the wheels themselves be pretty large. For, let the machine ABC (fig. 13.) (equal in length and height to ABM, fig. 12.) be provided with four wheels, whereof two appear at D and E, and the third under C, whilst the fourth is hid from sight by the horizontal board *a*. Let the cylinder

F be laid upon the lower end of the inclined plane CB, and the line G be extended from the frame of the cylinder, about six feet parallel to the plane CB; and, in that direction, fixed to a hook in the wall; which will support the cylinder, and keep it from rolling off the plane. Let one end of the line H be tied to a hook at C in the machine, and the other end to a weight K, the same as drew the cylinder up the plane before. If this line be put over the fixed pulley I, the weight K will draw the machine along the horizontal plane L, and under the cylinder F: and when the machine has been drawn the whole length CB, the cylinder will be raised to *d*, equal to the perpendicular height AB above the horizontal part at A.

To the inclined plane may be reduced all hatchets, chisels, and other edge tools which are chamfred only on one side.

5. The fifth mechanical power or engine is the *wedge*, which may be considered as two equally inclined planes DEF and CEF, joined together at their bases *e* EF: then DC (Plate CVIII. fig. 1.) is the whole thickness of the wedge at its back ABCD, where the power is applied; EF is the depth or height of the wedge; DF the length of one of its sides, equal to CF the length of the other side; and OF is its sharp edge, which is entered into the wood intended to be split by the force of a hammer or mallet (striking perpendicularly on its back. Thus, ABb (fig. 2.) is a wedge driven into the cleft CDE of the wood FG.

When the wood does not cleave at any distance before the wedge, there will be an equilibrium between the power impelling the wedge downward, and the resistance of the wood acting against the two sides of the wedge; if the power be to the resistance, as half the thickness of the wedge at its back is to the length of either of its sides; that is, as *Aa* to *Ab*, or *Ba* to *Bb* (fig. 2.) And if the power be increased, so as to overcome the friction of the wedge and the resistance arising from the cohesion or stickage of the wood, the wedge will be drove in, and the wood split asunder.

But, when the wood cleaves at any distance before the wedge (as it generally does) the power impelling the wedge will not be to the resistance of the wood, as half the thickness of the wedge is to the length of one of its sides; but as half its thickness is to the length of either side of the cleft, estimated from the top or acting part of the wedge. For, if we suppose the wedge to be lengthened down from *b* to the bottom of the cleft at E, the same proportion will hold; namely, that the power will be to the resistance, as half the thickness of the wedge is to the length of either of its sides: or, which amounts to the same thing, as the whole thickness of the wedge is to the length of both its sides.

In order to prove what is here advanced concerning the wedge, let us suppose the wedge to be divided lengthwise into two equal parts; and then it will become two equally inclined planes; one of which, as *abc*, (Plate CVII. fig. 14.) may be made use of as a half wedge for separating the moulding *cd* from the waincot AB. It is evident, that when this half-wedge has been driven its whole length *ac* between the waincot and moulding, its side *ac* will be at *ed*; and the moulding will be separated to

to fg from the waincoat. Now, from what has been already proved of the inclined plane, it appears, that to have an equilibrium between the power impelling the half wedge and the resistance of the moulding, the former must be to the latter as ab to ac ; that is, as the thickness of the back which receives the stroke is to the length of the side against which the moulding acts. Therefore, since the power upon the half wedge is to the resistance against its side, as the half back ab is to the whole side ac , it is plain, that the power upon the whole wedge (where the whole back is double the half back) must be to the resistance against both its sides, as the thickness of the whole back is to the length of both the sides, supposing the wedge at the bottom of the cleft; or as the thickness of the whole back to the length of both sides of the cleft, when the wood splits at any distance before the wedge. For, when the wedge is driven quite into the wood, and the wood splits at ever so small a distance before its edge, the top of the wedge then becomes the acting part, because the wood does not touch it any where else. And since the bottom of the cleft must be considered as that part where the whole stickage or resistance is accumulated, it is plain, from the nature of the lever, that the farther the power acts from the resistance, the greater is the advantage.

Some writers have advanced, that the power of the wedge is to the resistance to be overcome, as the thickness of the back of the wedge is to the length only of one of its sides; which seems very strange: for, if we suppose AB (Plate CVIII. fig. 3.) to be a strong inflexible bar of wood or iron fixed into the ground at CB, and D and E to be two blocks of marble lying on the ground on opposite sides of the bar, it is evident that the block D may be separated from the bar to the distance d , equal to ab , by driving the inclined plane or half wedge abo down between them; and the block E may be separated to an equal distance on the other side, in like manner, by the half wedge cdo . But the power impelling each half wedge will be to the resistance of the block against its side, as the thickness of that half wedge is to the length of its acting side. Therefore the power to drive both the half wedges is to both the resistances, as both the half backs is to the length of both the acting sides, or as half the thickness of the whole back is to the length of either side. And, if the bar be taken away, the blocks put close together, and the two half wedges joined to make one; it will require as much force to drive it down between the blocks, as is equal to the sum of the separate powers acting upon the half wedges when the bar was between them.

To confirm this by an experiment, let two cylinders, as AB (fig. 4.) and CD, be drawn towards one another by lines running over fixed pulleys, and a weight of 40 ounces hanging at the lines belonging to each cylinder: and let a wedge of 40 ounces weight, having its back just as thick as either of its sides is long, be put between the cylinders, which will then act against each side with a resistance equal to 40 ounces, whilst its own weight endeavours to bring it down and separate them. And here, the power of the wedge's gravity impelling it downward, will be to the resistance of both the cylinders against the wedge, as the thickness of the wedge is to the length of both its sides; for there will then be an equilibrium between the weight

of the wedge and the resistance of the cylinders against it, and it will remain at any height between them; requiring just as much power to push it upward as to pull it downward.—If another wedge of equal weight and depth with this, and only half as thick, be put between the cylinders, it will require twice as much weight to be hung at the ends of the lines which draw them together, to keep the wedge from going down between them. That is, a wedge of 40 ounces, whose back is only equal to half the length of one of its sides, will require 80 ounces to each cylinder, to keep it in an equilibrium between them: and twice 80 is 160, equal to four times 40. So that the power will be always to the resistance, as the thickness of the back of the wedge is to the length (not of its one side, but) of both its sides.

The best way, though perhaps not the neatest, for making a wedge with its appurtenances for such experiments, is as follows. Let IKLM (fig. 4.) and LMNO be two flat pieces of wood, each about fifteen inches long and three or four in breadth, joined together by a hinge at LM; and let P be a graduated arch of brass, on which the said pieces of wood may be opened to any angle not more than 60 degrees, and then fixed at the given angle by means of the two screws a and b . Then, IKNO will represent the back of the wedge, LM its sharp edge which enters the wood, and the outsidings of the pieces IKLM and LMNO the two sides of the wedge against which the wood acts in cleaving. By means of the said arch, the wedge may be opened so as to adjust the thickness of its back in any proportion to the length of either of its sides, but not to exceed that length: and any weight, as p , may be hung to the wedge upon the hook M, which weight, together with the weight of the wedge itself, may be considered as the impelling power; which is all the same in experiment, whether it be laid upon the back of the wedge to push it down, or hung to its edge to pull it down.—Let AB and CD be two wooden cylinders, each about two inches thick, where they touch the outsidings of the wedge; and let their ends be made like two round flat plates, to keep the wedge from slipping off endwise between them. Let a small cord with a loop on one end of it go over a pivot in the end of each cylinder, and the cords S and T belonging to the cylinder AB go over the first pulleys W and X, and be fastened at their other ends to the bar ax , on which any weight, as Z, may be hung at pleasure. In like manner, let the cords Q and R belonging to the cylinder BC go over the first pulleys U and V to the bar av , on which a weight Y equal to Z may be hung. These weights, by drawing the cylinders towards one another, may be considered as the resistance of the wood acting equally against opposite sides of the wedge; the cylinders themselves being suspended near and parallel to each other, by their pivots in loops on the lines E, F, G, H; which lines may be fixed to hooks in the ceiling of the room. The longer these lines are, the better; and they should never be less than four feet each. The further also the pulleys W, V and W, X are from the cylinders, the truer will the experiments be; and they may turn upon pins fixed into the wall.

In this machine, the weights Y and Z, and the weight p , may be varied at pleasure, so as to be adjusted in proportion

portion of the length of the wedge's side to the thickness of its back; and when they are so adjusted, the wedge will be in *equilibrium* with the resistance of the cylinders.

The wedge is a very great mechanical power, since not only wood but even rocks can be split by it; which would be impossible to effect by the lever, wheel and axle, or pulley: for the force of the blow, or stroke, shakes the cohering parts, and thereby makes them separate the more easily.

6. The sixth and last mechanical power is the *screw*; which cannot properly be called a simple machine, because it is never used without the application of a lever or winch to assist in turning it: and then it becomes a compound engine of a very great force either in pressing the parts of bodies close together, or in raising great weights. It may be conceived to be made by cutting a piece of paper ABC (fig. 5.) into the form of an inclined plane or half wedge, and then coiling it round a cylinder AB (fig. 6.) And here it is evident, that the winch E must turn the cylinder once round before the weight or resistance D can be moved from one spiral winding to another, as from *d* to *c*: therefore, as much as the circumference of a circle described by the handle of the winch is greater than the interval or distance between the spirals, so much is the force of the screw. Thus, supposing the distance between the spirals to be half an inch, and the length of the winch to be twelve inches; the circle described by the handle of the winch where the power acts will be 76 inches nearly, or about 152 halfinches, and consequently 152 times as great as the distance between the spirals: and therefore, a power at the handle, whose intensity is equal to no more than a single pound, will balance 152 pounds acting against the screw; and as much additional force, as is sufficient to overcome the friction, will raise the 152 pounds; and the velocity of the power will be to the velocity of the weight, as 152 to 1. Hence it appears, that the longer the winch be made, and the nearer the spirals are to one another, so much the greater is the force of the screw.

A machine for shewing the force or power of the screw may be contrived in the following manner. Let the wheel C (fig. 7.) have a screw *ab* on its axis, working in the teeth of the wheel D, which suppose to be 48 in number. It is plain, that for every time the wheel C and screw *ab* are turned round by the winch A, the wheel D will be moved one tooth by the screw; and therefore, in 48 revolutions of the winch, the wheel D will be turned once round. Then, if the circumference of a circle described by the handle of the winch be equal to the circumference of a groove *e* round the wheel D, the velocity of the handle will be 48 times as great as the velocity of any given point in the groove. Consequently, if a line G (above number 48) goes round the groove *e*, and has a weight of 48 pounds hung to it below the pedestal EF, a power equal to one pound at the handle will balance and support the weight. To prove this by experiment, let the circumferences of the grooves of the wheels C and D be equal to one another; and then if a weight H of one pound be suspended by a line going round the groove of the wheel C, it will balance a weight of 48 pounds hanging by the line

G; and a small addition to the weight H will cause it to descend, and so raise up the other weight.

If the line G, instead of going round the groove *e* of the wheel D, goes round its axle I; the power of the machine will be as much increased, as the circumference of the groove *e* exceeds the circumference of the axle: which, supposing it to be six times, then one pound at H will balance 6 times 48, or 288 pounds hung to the line on the axle: and hence the power or advantage of this machine will be as 288 to 1. That is to say, a man, who by his natural strength could lift an hundred weight, will be able to raise 288 hundred, or $14\frac{4}{5}$ ton weight by this engine.

But the following engine is still more powerful, on account of its having the addition of four pulleys: and in it we may look upon all the mechanical powers combined together, even if we take in the balance. For as the axis D (fig. 8.) of the bar AB is in its middle at C, it is plain that if equal weights are suspended upon any two pins equidistant from the axis C, they will counterpoise each other.—It becomes a lever by hanging a small weight P upon the pin *n*, and a weight as much heavier upon either of the pins *b, c, d, e*, or *f*, as is in proportion to the pins being so much nearer the axis. The wheel and axle FG is evident; so is the screw E, which takes in the inclined plane, and with it the half wedge. Part of a cord goes round the axle, the rest under the lower pulleys K, *m*, over the upper pulleys L, *n*, and then it is tied to a hook at *m* in the lower or moveable block, on which hangs the weight W.

In this machine, if the wheel F has 30 teeth, it will be turned once round in thirty revolutions of the bar AB, which is fixt on the axis D of the screw E: if the length of the bar is equal to twice the diameter of the wheel, the pins *a* and *n* at the ends of the bar will move 60 times as fast as the teeth of the wheel do: and consequently, one ounce at P will balance 60 ounces hung upon a tooth at *q* in the horizontal diameter of the wheel. Then, if the diameter of the wheel F is 10 times as great as the diameter of the axle G, the wheel will have 10 times the velocity of the axle; and therefore one ounce P at the end of the lever AC will balance 10 times 60 or 6000 ounces hung to the rope H which goes round the axle. Lastly, if four pulleys be added, they will make the velocity of the lower block K, and weight W, four times less than the velocity of the axle: and this being the last power in the machine, which is four times as great as that gained by the axle, it makes the whole power of the machine 4 times 600, or 2400. So that a man who could lift one hundred weight in his arms, by his natural strength, would be able to raise 2400 hundred weight by this engine.—But it is here as in all other mechanical cases; for the time lost is always as much as the power gained, because the velocity with which the power moves will ever exceed the velocity with which the weight rises, as much as the intensity of the weight exceeds the intensity of the power.

The friction of the screw itself is very considerable; and there are few compound engines, but what, upon account of the friction of the parts against one another,

will require a third part of more power to work them when loaded, than what is sufficient to constitute a balance between the weight and the power.

Of Mills, Cranes, Wheel carriages, and the Engine for driving Piles.

As these machines are so universally useful, it would be ridiculous to make any apology for describing them.

In a common *breast-mill*, where the fall of water may be about ten feet, AA (Plate CVIII. fig. 9.) is the great wheel, which is generally about 17 or 18 feet in diameter, reckoned from the outermost edge of any float-board at *a* to that of its opposite float at *b*. To this wheel the water is conveyed through a channel; and so, falling upon the wheel, turns it round.

On the axis BB of this wheel, and within the mill-house, is a wheel D, about 8 or 9 feet diameter, having 61 cogs, which turn a trundle E containing ten upright staves or rounds; and when these are the number of cogs and rounds, the trundle will make $6\frac{1}{2}$ revolutions for one revolution of the wheel.

The trundle is fixt upon a strong iron axis called the spindle, the lower end of which turns in a brass foot, fixt at F, in the horizontal beam ST called the bridge-tree; and the upper part of the spindle turns in a wooden bush fixt into the nether millstone which lies upon beams in the floor YY. The top part of the spindle above the bush is square, and goes into a square hole in a strong iron cross *abcd* (see fig. 3.) called the rynd; under which, and close to the bush, is a round piece of thick leather upon the spindle, which it turns round at the same time as it does the rynd.

The rynd is let into grooves in the under surface of the running millstone G (fig. 2.) and so turns it round in the same time that the trundle E is turned round by the cog-wheel D. This millstone has a large hole quite through its middle, called the eye of the stone, through which the middle part of the rynd and upper end of the spindle may be seen; whilst the four ends of the rynd lie hid below the stone in their grooves.

The end T of the bridge-tree TS (which supports the upper millstone G upon the spindle) is fixt into a hole in the wall; and the end S is let into a beam QR called the brayer, whose end R remains fixt in a mortise; and its other end Q hangs by a strong iron rod P which goes through the floor YY, and has a screw-nut on its top at O; by the turning of which nut, the end Q of the brayer is raised or depressed at pleasure, and consequently the bridge-tree TS and upper millstone. By this means, the upper millstone may be set as close to the under one, or raised as high from it, as the miller pleases. The nearer the millstones are to one another, the finer they grind the corn; and the more remote from one another, the coarser.

The upper millstone G is inclosed in a round box H, which does not touch it any where; and is about an inch distant from its edge all around. On the top of this box stands a frame for holding the hopper *kk*, to which is hung the shoe I by two lines fastened to the hind-part of it, fixed upon hooks in the hopper, and by one end of the crook-string K fastened to the fore-part of it at *i*; the o-

ther end being twisted round the pin L. As the pin is turned one way, the string draws up the shoe closer to the hopper, and so lessens the aperture between them; and as the pin is turned the other way, it lets down the shoe, and enlarges the aperture.

If the shoe be drawn up quite to the hopper, no corn can fall from the hopper into the mill; if it be let a little down, some will fall: and the quantity will be more or less, according as the shoe is more or less let down. For the hopper is open at bottom, and there is a hole in the bottom of the shoe, not directly under the bottom of the hopper, but forward towards the end *i*, over the middle of the eye of the millstone.

There is a square hole in the top of the spindle, in which is put the feeder *e* (fig. 10.) This feeder (as the spindle turns round) jogs the shoe three times in each revolution, and so causes the corn to run constantly down from the hopper, through the shoe, into the eye of the millstone, where it falls upon the top of the rynd, and is, by the motion of the rynd and the leather under it, thrown below the upper stone, and ground between it and the lower one. The violent motion of the stone creates a centrifugal force in the corn going round with it, by which means it gets farther and farther from the centre, as in a spiral, in every revolution, until it be thrown quite out; and, being then ground, it falls through a spout M, called the mill-eye, into the trough N.

When the mill is fed too fast, the corn bears up the stone, and is ground too coarse; and besides, it clogs the mill so as to make it go too slow. When the mill is too slowly fed, it goes too fast, and the stones by their attrition are apt to strike fire against one another. Both which inconveniences are avoided by turning the pin L backwards or forwards, which draws up or lets down the shoe; and so regulates the feeding as the miller sees convenient.

The heavier the running millstone is, and the greater the quantity of water that falls upon the wheel, so much the faster will the mill bear to be fed; and consequently so much the more it will grind. And on the contrary, the lighter the stone, and the less the quantity of water, so much slower must the feeding be. But when the stone is considerably wore, and become light, the mill must be fed slowly at any rate; otherwise the stone will be too much borne up by the corn under it, which will make the meal coarse.

The quantity of power required to turn a heavy millstone is but a very little more than what is sufficient to turn a light one: for as it is supported upon the spindle by the bridge-tree ST, and the end of the spindle that turns in the brass foot therein being but small, the odds arising from the weight is but very inconsiderable in its action against the power or force of the water. And besides, a heavy stone has the same advantage as a heavy fly; namely, that it regulates the motion much better than a light one.

In order to cut and grind the corn, both the upper and under millstones have channels or furrows cut into them, proceeding obliquely from the centre towards the circumference. And these furrows are each cut perpendicularly on one side and obliquely on the other into the stone, which

which gives each furrow a sharp edge, and in the two stones they come, as it were, against one another like the edges of a pair of scissars: and so cut the corn, to make it grind the easier when it falls upon the places between the furrows. These are cut the same way in both stones when they lie upon their backs, which makes them run cross ways to each other when the upper stone is inverted by turning its furrowed surface towards that of the lower. For, if the furrows of both stones lay the same way, a great deal of the corn would be driven onward in the lower furrows, and so come out from between the stones without ever being cut.

When the furrows became blunt and shallow by wearing, the running stone must be taken up, and both stones new dressed with a chisel and hammer. And every time the stone is taken up, there must be some tallow put round the spindle upon the bush, which will soon be melted by the heat that the spindle acquires from its turning and rubbing against the bush, and so will get in betwixt them: otherwise the bush would take fire in a very little time.

The bush must embrace the spindle quite close, to prevent any shake in the motion; which would make some parts of the stones grate and fire against each other; whilst other parts of them would be too far asunder, and by that means spoil the meal in grinding.

Whenever the spindle wears the bush so as to begin to shake in it, the stone must be taken up, and a chisel drove into several parts of the bush; and when it is taken out, wooden wedges must be driven into the holes; by which means the bush will be made to embrace the spindle close all around it again. In doing this, great care must be taken to drive equal wedges into the bush on opposite sides of the spindle; otherwise it will be thrown out of the perpendicular, and so hinder the upper stone from being set parallel to the under one, which is absolutely necessary for making good work. When any accident of this kind happens, the perpendicular position of the spindle must be restored by adjusting the bridge-tree ST by proper wedges put between it and the brayer QR.

It often happens, that the rynd is a little wrenched in laying down the upper stone upon it; or is made to sink a little lower upon one side of the spindle than on the other; and this will cause one edge of the upper stone to drag all around upon the other, whilst the opposite edge will not touch. But this is easily set to rights, by raising the stone a little with a lever, and putting bits of paper, cards, or thin chips, betwixt the rynd and the stone.

The diameter of the upper stone is generally about six feet, the lower stone about an inch more; and the upper stone when new contains about $22\frac{1}{2}$ cubic feet, which weighs somewhat more than 1900 pounds. A stone of this diameter ought never to go more than 60 times round in a minute; for if it turns faster, it will heat the meal.

The grinding surface of the under stone is a little convex from the edge to the centre, and that of the upper stone a little more concave: so that they are farthest from one another in the middle, and come gradually nearer towards the edges. By this means, the corn at

its first entrance between the stones is only bruised; but as it goes farther on towards the circumference or edge, it is cut smaller and smaller; and at last finely ground just before it comes out from between them.

The water-wheel must not be too large, for if it be, its motion will be too slow; nor too little, for then it will want power. And for a mill to be in perfection, the floats of the wheel ought to move with a third part of the velocity of the water, and the stone to turn round once in a second of time.

Such a mill as this, with a fall of water about $7\frac{1}{2}$ feet, will require about 32 hogheads every minute to turn the wheel with a third part of the velocity with which the water falls, and to overcome the resistance arising from the friction of the geers and attrition of the stones in grinding the corn.

The greater fall the water has, the less quantity of it will serve to turn the mill. The water is kept up in the mill-dam, and let out by a sluice called the penstock, when the mill is to go. When the penstock is drawn up by means of a lever, it opens a passage through which the water flows to the wheel; and when the mill is to be stopped, the penstock is let down, which stops the water from falling upon the wheel.

A less quantity of water will turn an overshot-mill (where the wheel has buckets instead of float boards) than a breast mill where the fall of the water seldom exceeds half the height AB of the wheel. So that where there is but a small quantity of water, and a fall great enough for the wheel to lie under it, the bucket (or overshot) wheel is always used. But where there is a large body of water, with a little fall, the breast or float board wheel must take place. Where the water runs only upon a little declivity, it can act but slowly upon the under part of the wheel at b; in which case the motion of the wheel will be very slow: and therefore, the floats ought to be very long, though not high, that a large body of water may act upon them; so that what is wanting in velocity may be made up in power; and then the cog-wheel may have a greater number of cogs in proportion to the rounds in the trundle, in order to give the millstone a sufficient degree of velocity.

They who have read what is said in the first section, concerning the acceleration of bodies falling freely by the power of gravity acting constantly and uniformly upon them, may perhaps ask, Why should the motion of the wheel be equable, and not accelerated, since the water acts constantly and uniformly upon it? The plain answer is, That the velocity of the wheel can never be so great as the velocity of the water that turns it; for, if it should become so great, the power of the water would be quite lost upon the wheel, and then there would be no proper force to overcome the friction of the geers and attrition of the stones. Therefore, the velocity with which the wheel begins to move, will increase no longer than till its momentum or force is balanced by the resistance of the machine; and then the wheel will go on with an equable motion.

[If the cog-wheel D be made about 18 inches diameter, with 30 cogs, the trundle as small in proportion with 10 slaves, and the millstones be each about two feet in diameter, and the whole work be put into a strong frame of wood,

as represented in the figure, the engine will be a hand-mill for grinding corn or malt in private families. And then, it may be turned by a winch, instead of the wheel AA; the millstone making three revolutions for every one of the winch. If a heavy fly be put upon the axle B, near the winch, it will help to regulate the motion.]

If the cogs of the wheel and rounds of the trundle could be put in as exactly as the teeth are cut in the wheels and pinions of a clock, then the trundle might divide the wheel exactly; that is to say, the trundle might make a given number of revolutions for one of the wheel, without a fraction. But as any exact number is not necessary in mill-work, and the cogs and rounds cannot be set in so truly as to make all the intervals between them equal; a skilful mill-wright will always give the wheel what he calls a *bunting cog*; that is, one more than what will answer to an exact division of the wheel by the trundle. And then, as every cog comes to the trundle, it will take the next staff or round behind the one which it took in the former revolution: and by that means, will wear all the parts of the cogs and rounds which work upon one another equally, and to equal distances from one another in a little time; and so make a true uniform motion throughout the whole work. Thus, in the above water-mill, the trundle has 10 staves, and the wheel 61 cogs.

Sometimes, where there is a sufficient quantity of water, the cog-wheel AA (Plate CIX. fig. 1.) turns a large trundle BB, on whose axis C is fixed the horizontal wheel D, with cogs all round its edge, turning two trundles E and F at the same time; whose axes or spindles G and H turn two millstones I and K, upon the fixed stones L and M. And when there is not work for them both, either may be made to lie quiet, by taking out one of the staves of its trundle, and turning the vacant place towards the cog-wheel D. And there may be a wheel fixt on the upper end of the great upright axle C for turning a couple of boulting-mills, and other work for drawing up the sacks, fanning and cleaning the corn, sharpening of tools, &c.

If, instead of the cog-wheel AA and trundle BB, horizontal levers be fixed into the axle C, below the wheel D; then, horses may be put to these levers for turning the mill; which is often done where water cannot be had for that purpose.

The working parts of a wind-mill differ very little from those of a water mill; only the former is turned by the action of the wind upon four sails, every one of which ought (as is generally believed) to make an angle of $54\frac{1}{2}$ degrees with a plane perpendicular to the axis on which the arms are fixt for carrying them; it being demonstrable, that when the sails are set to such an angle, and the axis turned end-ways toward the wind, the wind has the greatest power upon the sails. But this angle answers only to the case of a vane or sail just beginning to move: for, when the vane has a certain degree of motion, it yields to the wind; and then that angle must be increased to give the wind its full effect.

Again, the increase of this angle should be different, according to the different velocities from the axis to the extremity of the vane. At the axis it should be $54\frac{1}{2}$ degrees, and thence continually increase, giving the vane a

twist, and so causing all the ribs of the vane to lie in different planes.

Lally, these ribs ought to decrease in length from the axis to the extremity, giving the vane a curvilinear form; so that no part of the force of any one rib be spent upon the rest, but all move on independent of each other. All this is required to give the sails of a wind-mill their true form: and we see both the twist and the diminution of the ribs exemplified in the wings of birds.

It is almost incredible to think with what velocity the tips of the sails move when acted upon by a moderate gale of wind. We have several times counted the number of revolutions made by the sails in ten or fifteen minutes; and from the length of the arms from tip to tip, have computed, that if a hoop of that diameter was to run upon the ground with the same velocity that it would move if put upon the sail-arms, it would go upwards of 30 miles in an hour.

As the ends of the sails nearest the axis cannot move with the same velocity that the tips or farthest ends do, although the winds act equally strong upon them; perhaps a better position than that of stretching them along the arms directly from the centre of motion, might be to have them set perpendicularly across the farther ends of the arms, and there adjusted lengthwise to the proper angle. For, in that case, both ends of the sails would move with the same velocity; and being farther from the centre of motion, they would have so much the more power; and then, there would be no occasion for having them so large as they are generally made, which would render them lighter, and consequently there would be so much the less friction on the thick neck of the axle where it turns in the wall.

A crane is an engine by which great weights are raised to certain heights, or let down to certain depths. It consists of wheels, axles, pulleys, ropes, and a gib or gibbet. When the rope H (fig. 2.) is hooked to the weight K, a man turns the winch A, on the axis whereof is the trundle B, which turns the wheel C, on whose axis D is the trundle E, which turns the wheel F with its upright axis G, on which the great rope HH winds as the wheel turns; and going over a pulley I at the end of the arm *d* of the gib *cde*, it draws up the heavy burden K, which being raised to a proper height, as from a ship to the quay, is then brought over the quay by pulling the wheel Z round by the handles *z, z*, which turns the gib by means of the half wheel *b* fixt on the gib-post *cc*, and the strong pinion *a* fixt on the axis of the wheel Z. This wheel gives the man that turns it an absolute command over the gib, so as to prevent it from taking any unlucky swing, such as often happens when it is only guided by a rope tied to its arm *d*; and people are frequently hurt, sometimes killed, by such accidents.

The great rope goes between two upright upright rollers *i* and *k*, which turn upon gudgeons in the fixed beams *f* and *g*: and as the gib is turned towards either side, the rope bends upon the roller next that side. Were it not for these rollers, the gib would be quite unmanageable; for the moment it were turned ever so little towards any side, the weight K would begin to descend, because the rope would be shortened between the pulley

I and axis *G*; and so the gib would be pulled violently to that side, and either be broken to pieces, or break every thing that came in its way. These rollers must be placed so, that the sides of them, round which the rope bends, may keep the middle of the bended part directly even with the centre of the hole in which the upper gudgeon of the gib turns in the beam *f*. The truer these rollers are placed, the easier the gib is managed, and the less apt to swing either way by the force of the weight *K*.

A ratchet-wheel *Q* is fixt upon the axis *D*, near the trundle *E*; and unto this wheel falls the catch or click *R*. This hinders the machine from running back by the weight of the burden *K*, if the man who raises it should happen to be careless, and so leave off working at the winch *A* sooner than he ought to do.

When the burden *K* is raised to its proper height from the ship, and brought over the quay by turning the gib about, it is let down gently upon the quay, or into a cart standing thereon, in the following manner: *A* man takes hold of the rope *u* (which goes over the pulley *v*, and is tied to a hook at *S* in the catch *R*) and so disengages the catch from the ratchet wheel *Q*; and then, the man at the winch *A* turns it backward, and lets down the weight *K*. But if the weight pulls too hard against this man, another lays hold of the handle *V*, and by pulling it downward, draws the gripe *U* close to the wheel *Y*, which, by rubbing hard against the gripe, hinders the too quick descent of the weight; and not only so, but even stops it at any time, if required. By this means, heavy goods may be either raised or let down at pleasure, without any danger of hurting the men who work the engine.

When part of the goods are craned up, and the rope is to be let down for more, the catch *R* is first disengaged from the ratchet-wheel *Q*, by pulling the cord *t*; then the handle *g* is turned half round backward, which, by the crank *nn* in the piece *o*, pulls down the frame *h* between the guides *m* and *m* (in which it slides in a groove) and so disengages the trundle *B* from the wheel *C*; and then, the heavy hook *β* at the end of the rope *H* descends by its own weight, and turns back the great wheel *F* with its trundle *E*, and the wheel *C*; and this last wheel acts like *α* fly against the wheel *E* and hook *β*, and so hinders it from going down too quick; whilst the weight *X* keeps up the gripe *U* from rubbing against the wheel *Y*, by means of a cord going from the weight, over the pulley *ω* to the hook *W* in the gripe; so that the gripe never touches the wheel, unless it be pulled down by the handle *V*.

When the crane is to be set at work again, for drawing up another burden, the handle *g* is turned half round forwards; which, by the crank *nn*, raises up the frame *h*, and causes the trundle *B* to lay hold of the wheel *C*; and then, by turning the winch *A*, the burden of goods *K* is drawn up as before.

The crank *nn* turns pretty stiff in the mortise near *o*, and stops against the farther end of it when it has got just a little beyond the perpendicular; so that it can never come back of itself; and therefore the trundle *B* can never come away from the wheel *C*, until the handle *g* be turned half round.

The great rope runs on rollers in the lever *LM*,

which keep it from bending between the axle at *G* and the pulley *I*. This lever turns upon the axis *N* by means of the weight *O*, which is just sufficient to keep its end *L* up to the rope; so that, as the great axle turns, and the rope coils round it, the lever rises with the rope, and prevents the coils from going over one another,

The power of this crane may be estimated thus: Suppose the trundle *B* to have 13 flaves or rounds, and the wheel *C* to have 78 spur cogs; the trundle *E* to have 14 flaves, and the wheel *F* 56 cogs: then, by multiplying the flaves of the trundles, 13 and 14, into one another, their product will be 182; and by multiplying the cogs of the wheels, 78 and 56, into one another, their product will be 4368; and dividing 4368 by 182, the quotient will be 24; which shews that the winch *A* makes 24 turns for one turn of the wheel *F* and its axle *G* on which the great rope or chain *HH* winds. So that, if the length or radius of the winch *A* were only equal to half the diameter of the great axle *G*, added to half the thickness of the rope *H*, the power of the crane would be as 24 to 1: but the radius of the winch being double the above length, it doubles the said power, and so makes it as 48 to 1: in which case a man may raise 48 times as much weight by this engine as he could do by his natural strength without it, making proper allowance for the friction of the working parts. — Two men may work at once, by having another winch on the opposite end of the axis of the trundle under *B*; and so make the power still double.

If this power be thought greater than what may be generally wanted, the wheels may be made with fewer cogs in proportion to the flaves in the trundles: and so the power may be of whatever degree is judged to be requisite. But if the weight be so great as will require yet more power to raise it (suppose a double quantity) then the rope *H* may be put under a moveable pulley, as *h*, and the end of it tied to a hook in the gib at *ε*; which will give a double power to the machine, and so raise a double weight hooked to the block of the moveable pulley.

When only small burdens are to be raised, this may be quickly done by men pushing the axle *G* round by the hand-spokes *yy, yy*; having first disengaged the trundle *B* from the wheel *C*; and then, this wheel will only act as a fly upon the wheel *F*; and the catch *R* will prevent its running back, if the men should inadvertently leave off pushing before the burden be unhooked from *β*.

Lastly, when very heavy burdens are to be raised, which might endanger the breaking of the cogs in the wheel *F*; their force against these cogs may be much abated by men pushing round the hand-spokes *yy, yy*, whilst the man at *A* turns the winch.

We have only shewn the working parts of this crane, without the whole of the beams which support them; knowing that these are easily supposed, and that if they had been drawn, they would have hid a great deal of the working parts from sight, and also confused the figure.

Another very good crane is made in the following manner. *AA* (fig. 3.) is a great wheel turned by men walking within it at *H*. On the part *C*, of its axle *BC*, the great rope *D* is wound as the wheel turns; and this

rope

rope draws up goods in the same way as the rope HH does in the above-mentioned crane, the gib-work here being supposed to be of the same fort. But these cranes are very dangerous to the men in the wheel; for, if any of the men should chance to fall, the burden will make the wheel run back and throw them all about within it; which often breaks their limbs, and sometimes kills them. The late ingenious Mr *Padmore* of Bristol, whose contrivance the forementioned cranes is, observing this dangerous construction, contrived a method for remedying it, by putting cogs all around the outside of the wheel, and applying a trundle E to turn it; which increases the power as much as the number of cogs in the wheel is greater than the number of staves in the trundle: and by putting a ratchet-wheel F on the axis of the trundle, (as in the above-mentioned crane, with a catch to fall into it, the great wheel is stopped from running back by the force of the weight, even if all the men in it should leave off walking. And by one man working at the winch I, or two men at the opposite winches when needful, the men in the wheel are much assisted, and much greater weights are raised, than could be by men only within the wheel. Mr. *Padmore* put also a gripe-wheel G upon the axis of the trundle, which being pinched in the same manner as described in the former crane, heavy burdens may be let down without the least danger. And before this contrivance, the lowering of goods was always attended with the utmost danger to the men in the wheel; as every one must be sensible of, who has seen such engines at work.

And it is surprising that the masters of wharfs and cranes should be so regardless of the limbs, or even lives of their workmen, that, excepting the late Sir *Jam. Creed* of Greenwich, and some gentlemen at Bristol, there is scarce an instance of any who has used this safe contrivance.

THE structure of wheel-carriages is generally so well known, that it would be needless to describe them. And therefore, we shall only point out some inconveniences attending the common method of placing the wheels, and loading the waggon.

In coaches, and all other four-wheeled carriages, the fore-wheels are made of a less size than the hind ones, both on account of turning short, and to avoid cutting the braces: otherwise, the carriage would go much easier if the fore-wheels were as high as the hind ones; and the higher the better, because their motion would be so much the slower on their axles, and consequently the friction proportionably taken off. But carriers and coachmen give another reason for making the fore-wheels much lower than the hind-wheels; namely, that when they are so, the hind-wheels help to push on the fore ones: which is too unphilosophical and absurd to deserve a refutation; and yet for their satisfaction, we shall shew by experiment that it has no existence but in their own imaginations.

It is plain, that the small wheels must turn as much oftener round than the great ones, as their circumferences are less. And therefore, when the carriage is loaded equally heavy on both axles, the fore-axle must endure as much more friction, and consequently wear out

as much sooner, than the hind-axle, as the fore-wheels are less than the hind ones. But the great misfortune is, that all the carriers to a man do obligately perfit, against the clearest reason and demonstration, in putting the heavier part of the load upon the fore-axle of the waggon; which not only makes the friction greatest where it ought to be least, but also preffeth the fore-wheels deeper into the ground than the hind wheels, notwithstanding the fore-wheels, being less than the hind ones, are with so much the greater difficulty drawn out of a hole or over an obstacle, even supposing the weights on their axles were equal. For the difficulty, with equal weights, will be as the depth of the hole or height of the obstacle is to the semidiameter of the wheel. Thus, if we suppose the small wheel D (fig. 4) of the waggon AB to fall into a hole of the depth EF, which is equal to the semidiameter of the wheel, and the waggon to be drawn horizontally along; it is evident, that the point E of the small wheel will be drawn directly against the top of the hole; and therefore, all the power of horses and men will not be able to draw it out, unless the ground gives way before it. Whereas, if the hind wheel C falls into such a hole, it sinks not near so deep in proportion to its semidiameter; and therefore, the point G of the large wheel will not be drawn directly, but obliquely, against the top of the hole; and so will be easily got out of it. Add to this, that since a small wheel will often sink to the bottom of a hole, in which a great wheel will go but a very little way, the small wheels ought in all reason to be loaded with less weight than the great ones; and then the heavier part of the load would be less jolted upward and downward, and the horses tired so much the less as their draught raised the load to less heights.

It is true, that when the waggon road is much up hill, there may be danger in loading the hind part much heavier than the fore part; for then the weight would overhang the hind axle, especially if the load be high, and endanger tilting up the fore-wheels from the ground. In this case, the safest way would be to load it equally heavy on both axles; and then, as much more of the weight would be thrown upon the hind-axle than upon the fore one, as the ground rises from a level below the carriage. But as this seldom happens, and when it does, a small temporary weight laid upon the pole between the horses would overbalance the danger; and this weight might be thrown into the waggon when it comes to level ground; it is strange that an advantage so plain and so obvious as would arise from loading the hind-wheels heaviest, should not be laid hold of, by complying with this method.

To confirm these reasonings by experiment, let a small model of a waggon be made, with its fore-wheels $2\frac{1}{2}$ inches in diameter, and its hind-wheels $4\frac{1}{2}$; the whole model weighing about 20 ounces. Let this little carriage be loaded any how with weights, and have a small cord tied to each of its ends, equally high from the ground it rests upon; and let it be drawn along a horizontal board, first by a weight in a scale hung to the cord at the fore part; the cord going over a pulley at the end of the board to facilitate the draught, and the weight just sufficient to draw it along. Then, turn the carriage, and hang the scale and weight to the hind cord, and it will be

be found to move along with the same velocity as at first: which shews, that the power required to draw the carriage is all the same, whether the great or small wheels are foremost; and therefore the great wheels do not help in the least to push on the small wheels in the road.

Hang the scale to the fore cord, and place the fore wheels (which are the small ones) in two holes, cut three eighth-parts of an inch deep into the board; then put a weight of 32 ounces into the carriage, over the fore-axle, and an equal weight over the hind one: this done, put 44 ounces into the scale, which will be just sufficient to draw out the fore wheels: but if this weight be taken out of the scale, and one of 16 ounces put into its place, if the hind wheels are placed in the holes, the 16 ounces weight will draw them out; which is little more than a third part of what was necessary to draw out the fore-wheels. This shews, that the larger the wheels are, the less power will draw the carriage, especially on rough ground.

Put 64 ounces over the axle of the hind-wheels, and 32 over the axle of the fore ones, in the carriage; and place the fore wheels in the holes: then, put 38 ounces into the scale, which will just draw out the fore wheels; and when the hind ones come to the hole, they will find but very little resistance, because they sink but a little way into it.

But shift the weights in the carriage, by putting the 32 ounces upon the hind axle, and the 64 ounces upon the fore one; and place the fore wheels in the holes; then, if 76 ounces be put into the scale, it will be found no more than sufficient to draw out these wheels; which is double the power required to draw them out, when the lighter part of the load was put upon them: which is a plain demonstration of the absurdity of putting the heaviest part of the load in the fore part of the waggon.

Every one knows what an outcry was made by the generality, if not the whole body, of the carriers, against the broad-wheel act; and how hard it was to persuade them to comply with it, even though the government allowed them to draw with more horses, and carry greater loads, than usual. Their principal objection was, that as a broad wheel must touch the ground in a great many more points than a narrow wheel, the friction must of course be just so much the greater; and consequently, there must be so many more horses than usual, to draw the waggon. It is believed that the majority of people were of the same opinion, not considering, that if the whole weight of the waggon and load in it bears upon a great many points, each sustains a proportionally less degree of weight and friction, than when it bears only upon a few points; so that what is wanting in one, is made up in the other; and therefore will be just equal under equal degrees of weight, as may be shewn by the following plain and easy experiment.

Let one end of a piece of packthread be fastened to a brick, and the other end to a common scale for holding weights: then, having laid the brick edgewise on a table, and let the scale hang under the edge of the table, put as much weight into the scale as will just draw the brick along the table. Then taking back the brick to its former place, lay it flat on the table, and leave it to be act-

ed upon by the same weight in the scale as before, which will draw it along with the same ease as when it lay upon its edge. In the former case, the brick may be considered as a narrow wheel on the ground; and in the latter, as a broad wheel. And since the brick is drawn along with equal ease, whether its broad side or narrow edge touches the table, it shews that a broad wheel might be drawn along the ground with the same ease as a narrow one (supposing them equally heavy) even though they should drag, and not roll, as they go along.

As narrow wheels are always sinking into the ground, especially when the heaviest part of the load lies upon them, they must be considered as going constantly up hill, even on level ground; and their edges must sustain a great deal of friction by rubbing against the sides of the ruts made by them. But both these inconveniences are avoided by broad wheels; which, instead of cutting and ploughing up the roads, roll them smooth, and harden them; as experience testifies in places where they have been used, especially either on wet or sandy ground: though after all it must be confessed, that they will not do in stiff clayey cross-roads; because they would soon gather up as much clay as would be almost equal to the weight of an ordinary load.

If the wheels were always to go upon smooth and level ground, the best way would be to make the spokes perpendicular to the nave; that is, to stand at right angles to the axles; because they would then bear the weight of the load perpendicularly, which is the strongest way for wood. But because the ground is generally uneven, one wheel often falls into a cavity or rut when the other does not; and then it bears much more of the weight than the other does: in which case, concave or dishing wheels are best; because when one falls into a rut, and the other keeps upon high ground, the spokes become perpendicular in the rut, and therefore have the greatest strength when the obliquity of the load throws most of its weight upon them; whilst those on the high ground have less weight to bear, and therefore need not be at their full strength. So that the usual way of making the wheels concave is by much the best.

The axles of the wheels ought to be perfectly straight, that the rims of the wheels may be parallel to each other; for then they will move easiest, because they will be at liberty to go on straight forwards. But in the usual way of practice, the axles are bent downward at their ends; which brings the sides of the wheels next the ground nearer to one another than their opposite or higher sides are: and this not only makes the wheels to drag sideways as they go along, and gives the load a much greater power of crushing them than when they are parallel to each other, but also endangers the overturning of the carriage when any wheel falls into a hole or rut; or when the carriage goes in a road which has one side lower than the other, as along the side of a hill. Thus (in the hind view of a waggon or cart) let AE and BF (fig. 5.) be the great wheels parallel to each other, on their straight axle K, and HCL the carriage loaded with heavy goods from C to G. Then, as the carriage goes on in the oblique road AaB, the centre of gravity of the whole machine and load will be at C (see p. 35. col. 1.) and the

line of direction *CdD* falling within the wheel *BF*, the carriage will not overset. But if the wheels be inclined to each other at the ground, as *AE* and *BF* (fig. 6) are, and the machine be loaded as before, from *C* to *G*, the line of direction *CdD* falls without the wheel *BF*, and the whole machine tumbles over. When it is loaded with heavy goods (such as lead or iron) which lie low, it may travel safely upon an oblique road so long as the centre of gravity is at *C*, and the line of direction *Cd* (fig. 5.) falls within the wheels; but if it be loaded high with lighter goods (such as woolpacks) from *C* to *L*, (fig. 7.) the centre of gravity is raised from *C* to *K*, which throws the line of direction *Kk* without the lowest edge of the wheel *BF*, and then the load oversets the waggon.

If there be some advantage from small fore-wheels, on

account of the carriage turning more easily and short than it can be made to do when they are large; there is at least as great a disadvantage attending them, which is, that as their axle is below the level of the horses' breasts, the horses not only have the loaded carriage to draw along, but also part of its weight to bear; which tires them sooner, and makes them grow much stiffer in their hams, than they would be if they drew on a level with the fore axle: and for this reason, we find coach-horses soon become unfit for riding. So that on all accounts it is plain, that the fore-wheels of all carriages ought to be so high, as to have their axles even with the breasts of the horses; which would not only give the horses a fair draught, but likewise cause the machine to be drawn by a less degree of power.

M E D

MECHLIN, a large well built and fortified city of Brabant, twelve miles north east of Brussels.

MECHOACAN, a province of Mexico, bounded by Panuco, on the north; by Mexico Proper, on the east; by the Pacific ocean, on the south; and by Guadaluajara, or New Galicia, on the west.

MECKLENBURG DUCHY, a province of Germany, in the province of Lower Saxony, about 100 miles long, and 60 broad; bounded by the Baltic sea, on the north; by Pomerania, on the east; by Brandenburg, on the south; and by the duchies of Holstein, Lunenburg, and Lawenburg, on the west.

MECON, a great river, which rises in the north of further India, and, running south through the kingdoms of Laos and Cambodia, falls into the Indian ocean.

MECONIUM, in medicine, a black thick fæces gathered in the intestines of infants, and brought with them into the world at the time of their birth.

MECONIUM, in pharmacy, the extract of English poppies.

Meconium has all the virtues of the foreign opium, but in a somewhat lower degree. See **OPIMUM**.

MEDAL, a piece of metal in the form of coin, intending to convey to posterity the portrait of some great person, or the memory of some illustrious action.

The parts of a medal are the two sides, one of which is called the face or head, and the other the reverse. On each side is the area, or field, which makes the middle of the medal; the rim, or border; and the exergum: and one the two sides are distinguished the type or the figure represented, and the legend or inscription.

As to the antiquity of medals, the Greek are certainly the most ancient; for long before the building of Rome the Greeks had beautiful money in gold, silver, and copper. This plainly appears from several genuine medals of Macedon, older than Philip and Alexander; from Greek medals with the names of several magistrates prior to the Macedonian empire; to which we may add some Sicilian coins of still greater antiquity. As the Greek medals are the most ancient, so are they

M E D

the most beautiful; they have a design, accuracy, force, and delicacy, that expresses even the muscles and veins, and are struck with such exquisite art, as the Romans could never come up to. Those struck when Rome was governed by consuls, are the most ancient among the Romans: but the copper and silver medals do not go beyond the 484th year of Rome, nor the gold beyond the year 546. Among the imperial medals, we distinguish between the upper and lower empire: the first commenced under Julius Cæsar, and ended A. D. about 260; the lower empire includes near 1200 years, and ends at the taking of Constantinople. It is the custom, however, to account all the imperial medals till the time of the Paleologi, among the antique; though we have none of any considerable beauty later than the time of Heraclius, who died in 641. The Gothic medals make part of the imperial ones. Modern medals are those struck within these 300 years. There are no true Hebrew medals, except a few shekels of copper and silver, but none of gold; though there is mention made of one in the king of Denmark's cabinet.

There was formerly no difference between money and medals. An old Roman had his purse full of the same pieces that we now preserve in cabinets. As soon as an emperor had done any thing remarkable, as gaining a victory, giving up a tax, or the like, it was immediately stamped on a coin, and became current thro' his whole dominions. This was a pretty device to spread abroad the virtues of an emperor, and make his actions circulate; and thus a fresh coin was a kind of gazette, that published the latest news of the empire.

Several of our modern coins have the legend round the edges: but the ancients were too wise to register their exploits on so nice a surface. As to the figures upon medals, the Romans always appear in the proper dress of their country, so that we may observe the little variations of the mode in the drapery of the medal: they would have thought it ridiculous to have drawn an emperor of Rome in a Grecian cloak or a Phrygian mitre. On the contrary, we often see a king of England or France dressed up like a Julius Cæsar, as if they had a mind to pass themselves upon posterity for Roman

Roman emperors. Nothing is more usual than to see allusions to Roman customs and ceremonies on the medals of our own nation; nay, they very often carry the figure of an heathen god. If politeness take its notions of us from our medals, they must fancy that one of our kings paid a great devotion to Minerva, another to Apollo, &c. or, at least, that our whole religion was a mixture of paganism and Christianity. Had the old Romans been guilty of the same extravagance, there would have been so great a confusion in their antiquities, that their coins would not have had half the use we now find in them.

The use of medals is very considerable: they give a very great light into history, in confirming such passages as are true in old authors, in reconciling such as are told in different manners, and in recording such as have been omitted. In this case a cabinet of medals is a body of history. It was, indeed, the best way in the world to perpetuate the memory of great actions, thus to coin out the life of an emperor, and to put every exploit into the mint. It was a kind of painting before the art was invented: and they have this advantage over books, that they tell their story quicker, and sum up a whole volume in twenty or thirty verses: thus Mr Vaillant, out of a small collection of medals, has given us a chronicle of the kings of Syria. They are indeed the best epitomes in the world, and let us see, with one cast of the eye, the substance of above an hundred pages. Another use of medals is, that they not only shew the actions of an emperor, but at the same time mark out the year in which they were performed; for as every exploit has its date set to it, a series of an emperor's coins is his whole life digested into annals. A medallist, upon the first naming of an emperor, will immediately tell his age, family, and life. To remember where he enters in the succession, he only considers in what part of the cabinet he lies; and by running over in his thoughts such a particular drawer, will give an account of all the remarkable parts of his reign. Nor are medals of less use in architecture, painting, poetry, &c. A cabinet of medals is a collection of pictures in miniature, and by them the plans of many of the most considerable buildings of antiquity are preserved.

Impressions of MEDALS. A very easy and elegant way of taking the impressions of medals and coins, not generally known, is thus directed by Dr Shaw: Melt a little isinglass-glue made with brandy, and pour it thinly over the medals, so as to cover its whole surface: let it remain on for a day or two, till it is thoroughly dry and hardened; and then taking it off, it will be fine, clear, and hard, as a piece of Muscovy glass, and will have a very elegant impression of the coin.

Another easy method is as follows: Take a perfect and sharp impression, in the finest black sealing-wax, of the coin or medal you desire. Cut away the wax round the edges of the impression; then with a preparation of gum-water, of the colour you would have the picture, spread the paint upon the wax-impression with a small hair pencil, observing to work it into all

the sinking or hollow places, these being the rising parts of the medal; and the colour must be carefully taken from the other parts with a wet finger. Then take a piece of very thin post-paper, a little larger than the medal, and moisten it quite through. Place it on the wax impression; and on the back of the paper lay three or four pieces of thick woolen cloth or flannel, of about the same size. The impression, with its coverings, should be placed between two smooth iron plates, about two inches square, and one tenth of an inch thick. These must be carefully put into a small press, made of two plates of iron, about five inches and a half long, one inch and a half wide, and half an inch in thickness, having a couple of long male-screws running through them, with a turning female-screw on each, to force the plates together. These being brought evenly together, by means of the screws, will take off a true and fair picture of the medal; which, if any deficiencies should appear, may easily be repaired with a hair pencil, or pen, dipped in the colour made use of.

If a relievo only be desired, nothing is necessary, but to take a piece of card, or white paste-board, well soaked in water; then placing it on the wax-mould, without any colouring, and letting it remain in the press for a few minutes, a good figure will be obtained.

This method of taking off medals, &c. is convenient, and seems much more so than the several inventions usually practised in sulphur, plaster of Paris, paper, &c. wherein a mould must be formed, either of clay, horn, plaster, or other materials, which requires a good deal of time and trouble.

MEDALION, or MEDALION, a medal of an extraordinary size, supposed to be anciently struck by the emperors for their friends, and for foreign princes and ambassadors; but that the smallness of their number might not endanger the loss of the devices they bore, the Romans generally took care to stamp the subject of them upon their ordinary coins.

Medallions, in respect of the other coins, were the same as modern medals in respect of modern money: they were exempted from all commerce, and had no other value but what was set upon them by the fancy of the owner. Medallions are so scarce that there cannot be any set made of them, even though the metals and sizes should be joined promiscuously.

MEDELPAZIA, a small province of Sweden lying northward of Helsingia.

MEDEOLA, in botany, a genus of the hexandria trigynia class. It has no calix: the corolla consists of six revolved segments; and the berry contains three seeds. There are two species, none of them natives of Britain.

MEDIA, in geography, the ancient name of Gilan. See **GILAN**.

MEDIANA. See **ANATOMY**, p. 241.

MEDIASTINUM, in anatomy. See **ANATOMY**, p. 278.

MEDIATE, or INTERMEDIATE something that stands between and connects two or more terms, considered

† P as

as extremes; in which sense it is opposed to immediate.

MEDICAGO, in botany, a genus of the diadelphia decandria class. The pod is compressed; and the carina of the corolla declines from the vexillum. There

are nine species, four of them natives of Britain, *viz.* The falcata, or yellow medic; the fativa, or lucerna; the lupulina, or melilot trefoil; and the arabica, or heart-trefoil.

M E D I C I N E.

MEDICINE is generally defined to be, The art of preserving health when present, and of restoring it when lost.

Men would never think of any particular regimen or mode of living in order to preserve health, before they felt the pains which accompany the want it. The first painful sensation must necessarily have produced a desire for relief. But in a period when physicians and medicines were equally unknown, how was that relief to be obtained? or what system of conduct would man in this situation naturally follow? Whoever can answer these questions, will unfold the genuine principles of the medical art, and give an infallible standard for judging what progress has been made in the improvement of it, what particular circumstances have contributed to obstruct or forward the knowledge and cure of diseases.

Medicine being thus founded on a powerful instinct in human nature, its existence in some form must have been coeval with the first disease that appeared among mankind. Most arts require the experience of ages before they can arrive at a high degree of perfection. Medicine is unquestionably one of the most ancient; and consequently, the improvement of it might be expected to bear some proportion to its antiquity. But, whilst philosophy, in all its branches, has been cultivated and improved to a great extent; medicine, notwithstanding the collateral advantages it has of late derived from anatomy and other sciences, still continues to be buried in rubbish and obscurity.

Many causes have contributed to retard our progress in the knowledge of the causes and cure of diseases. In the early ages, prescriptions were either the result of tradition founded upon uncertain facts, or mere random trials without any rational view of success: Accordingly, when any uncommon case occurred, the patients were placed in cross-ways, and other public places, to receive the advice of passers by who might chance to know the disease or an efficacious remedy. In this way valuable medicines might be accidentally discovered. But memory, and, in remarkable cures, engravings on pillars or the walls of temples, were poor instruments for recording the symptoms of diseases, and the ingredients of prescriptions.

After the knowledge of medicine began to be studied and practised as a liberal profession, a jealousy of reputation, joined to a thirst for money and ignorance of philosophy, laid a solid foundation for medical disputation. One party of physicians, known by the name of Empirics, excluded all reasoning, and trusted solely to experience. Another party, called Dogmatists, maintained, that no man ought to prescribe, without being able to give a

theory both of the disease and of the nature and action of the medicine. This dispute continued for ages, and, like other disputes of a similar nature, remains still in some measure undecided. The principles of both these parties are unquestionably good. But the physician who excludes either of them, will make but little progress in the knowledge of his profession. A judicious mixture of the two is indispensably necessary. Indeed it is difficult to determine whether too great an attachment to empiricism or dogmatism has contributed most to obstruct the improvement of physic.

But there is one cause which has operated more powerfully in preventing the improvement of medicine than even a combination of all the other causes. Most branches of philosophy are principally cultivated by people who expect their reward in reputation, not in money. The practice of physic is become as literally a trade as any branch of business whatever. Young men are taught physic with no other view than that of gaining their bread. Whenever a physician gets into extensive practice, he may bustle and make a noise; but, even supposing his abilities to be great, he can never find leisure to think, or digest his observations.

Another cause of the imperfect state of medicine arises from the varieties in constitutions, and the complex nature of diseases. It is even extremely difficult, after a disease has been cured, to determine with certainty, whether the cure was performed by the operation of nature, or by any particular virtue in the medicine. This difficulty is greatly increased by the variety of different medicines, and different ingredients in the same medicine, which are commonly administered during the course of a disease.

Of late several attempts have been made to reduce medicine into the form of a regular science, by distributing diseases into classes, orders, genera, and species. Sauvage was the first, and indeed the only person who ever attempted to complete this great work. Others, as Linnaeus, Vogel, Dr Cullen, &c. have since endeavoured to improve Sauvage's method of classing; but they have contented themselves with an enumeration of the characters and arrangement of the different genera, without entering into their history or cure. Sauvage enumerates 315 genera, Linnaeus 325, Vogel 560, and Dr Cullen has reduced them to 132. The bare inspection of these numbers shews, that physicians are far from being agreed with regard to what constitutes the generic or specific characters of a disease. Indeed, we may venture to affirm, that they never will agree upon this point: The diagnostic symptoms of diseases are not so easily discovered as the stamina or petals in a flower, or the number of teeth or toes

in a quadruped. However, before making any observations on the advantages or disadvantages that may probably result from the classification of diseases, we shall lay before our readers the last and shortest distribution, published last year by Dr Cullen, one of the professors of medicine in the university of Edinburgh, under the title of *Synopsis Nosologie Methodica*, or rather, *Genera Morborum Præcipua*.

The doctor divides diseases into the four following classes, *viz.*

CLASS. I. PYREXIÆ, or Febrile Disorders.

II. NEUROSES, or Nervous Diseases.

III. CACHEXIÆ; comprehending such disorders as proceed from a diseased state of the whole or any part of the body, without an original fever, or any nervous complaint.

IV. LOCALES; comprehending diseases which affect a part only, not the whole body.

The first class (PYREXIÆ) is subdivided into five orders, *viz.*

ORDER I. FEBRES, or Fevers, is subdivided into two sections, *viz.* 1. Intermittent; and, 2. Continued fevers.—The first section contains three genera, *viz.*

1. The Tertian fever; 2. The Quartan; 3. The Quotidian:—The second section likewise contains three genera, *viz.* 1. The Synocha; 2. The Typhus; 3. The Synochus.

ORDER II. PHLEGMASIE, or fevers accompanied with any local pain. This order contains 17 genera, *viz.* 1. Phlegmon; 2. Ophthalmia; 3. Phrenitis; 4. Cynanche; 5. Peripneumonia; 6. Pleuritis; 7. Carditis; 8. Peritonitis; 9. Gastritis; 10. Enteritis; 11. Hepatitis; 12. Splentis; 13. Nephritis; 14. Cystitis; 15. Hysteritis; 16. Rheumatismus; 17. Arthritis.

ORDER III. EXANTHEMETA, or eruptive fevers; comprehending 10 genera, *viz.* 1. Erysipelas; 2. Pestis; 3. Variola; 4. Varicella; 5. Rubella; 6. Miliaria; 7. Scarlatina; 8. Urticaria; 9. Pemphigus; 10. Aphtha.

ORDER IV. HÆMORRHAGIÆ, or fevers accompanied with a flux of blood, not proceeding from any external cause. This order comprehends 4 genera, *viz.* Epistaxis; 2. Hæmoptysis; 3. Hæmorrhoids; 4. Menorrhagia.

ORDER V. PROFLUVIA, or fevers attended with an increased secretion, not naturally of the bloody kind. This order contains 2 genera, *viz.* 1. Catarrhus; 2. Dysenteria.

The second class (NEUROSES) is subdivided into four orders, *viz.*

ORDER I. COMATA, or lethargic diseases; containing 3 genera, *viz.* 1. Apoplexia; 2. Paralysis; 3. Catalepsis.

ORDER II. ADYNAMIÆ, or diseases arising from a stoppage or diminution in any of the involuntary motions, whether vital or natural. This order contains 4 genera, *viz.* 1. Syncope; 2. Dyspepsia; 3. Hypochondriasis; 4. Chlorosis.

ORDER III. SPASMI, or irregular motions of the muscular fibres. This order contains 13 genera, *viz.*

1. Tetanus; 2. Convulsio; 3. Epilepsia; 4. Palpitatio; 5. Asthma; 6. Pertussis; 7. Pyrosis; 8. Colica; 9. Cholera; 10. Diarrhœa; 11. Diabetes; 12. Hysteria; 13. Hydrophobia.

ORDER IV. VESANIÆ, or diseases of the mind, without a fever or coma. This order contains 4 genera, *viz.* 1. Amentia; 2. Melancholia; 3. Mania; 4. Somnium.

The third class (CACHEXIÆ, or diseases arising from a depraved state of the whole or a great part of the body, without a fever or nervous complaint,) is subdivided into 3 orders, *viz.*

ORDER I. MARCORES, or diseases attended with a wasting of the whole body; containing 2 genera, *viz.* 1. Tabes; 2. Atrophia.

ORDER II. INTUMESCENTIÆ, or diseases accompanied with an external swelling of the whole or a great part of the body. This order contains 13 genera, *viz.* 1. Polyfarcia; 2. Pneumatosis; 3. Tympanites; 4. Phylometra; 5. Anasarca; 6. Hydrocephalus; 7. Hydrorachitis; 8. Hydrothorax; 9. Ascites; 10. Hydrometra; 11. Hydrocele; 12. Phylsconia; 13. Rachitis.

ORDER III. IMPETIGINES, or diseases attended with a cachexy which deforms the skin and external parts of the body. This order contains 8 genera, *viz.* 1. Scrophula; 2. Syphilis; 3. Scorbutus; 4. Elephantiasis; 5. Lepra; 6. Frambœsia; 7. Trichoma; 8. Icterus.

The fourth class (LOCALES, or diseases affecting only a part of the body,) is subdivided into seven orders, *viz.*

ORDER I. DYSÆSTHESIÆ, or diseases arising from any of the senses being destroyed or impaired by a fault in the external organs of sensation. There are 8 genera in this order, *viz.* 1. Caligo; 2. Amblyopia; 3. Dysecœa; 4. Paracusis; 5. Anosmia; 6. Agheusia; 7. Anæsthesia; 8. Anaphrodisia.

ORDER II. DYSCHINESIÆ, or diseases attended with the destruction or defect of motion in any part through a fault of the organs. This order contains 6 genera, *viz.* 1. Aphonia; 2. Mutitas; 3. Paraphonia; 4. Pselismus; 5. Strabismus; 6. Contractura.

ORDER III. APOCENOSES, or diseases attended with an increased flux of the blood or other humours, without a fever, or increased motion of the fluids. This order contains 5 genera, *viz.* 1. Profusio; 2. Epiphora; 3. Pyralismus; 4. Enuresis; 5. Gonorrhœa.

ORDER IV. EPISCHESES, or diseases arising from a suppression or obstruction of any usual excretions. This order contains 3 genera, *viz.* 1. Oblitatio; 2. Ischuria; 3. Amenorrhœa.

ORDER V. TUMORES, or diseases attended with an increased size of the part, without a phlegmon. This order contains 14 genera, *viz.* 1. Aneurisma; 2. Varix; 3. Echinomoma; 4. Schirrus; 5. Cancer; 6. Bubo; 7. Sarcoma; 8. Verruca; 9. Clavus; 10. Lupia; 11. Ganglion; 12. Hydatid; 13. Hydrarthrus; 14. Exostosis.

ORDER VI. ECTOPIÆ, comprehending diseases arising

sing from any part's being removed from its proper situation, and causing a tumor. This order contains 3. genera, *viz.* 1. *Hæmia*; 2. *Psoriasis*; 3. *Luxatio*.

ORDER VII. DIALYSES; comprehending ulcers, and all kinds of wounds. This order contains 7 genera, *viz.* 1. *Vulnus*; 2. *Ulcus*; 3. *Herpes*; 4. *Tinea*; 5. *Psora*; 6. *Fractura*; 7. *Caries*.

It is needless to enter into an examination of the propriety or impropriety of this or any of the other modes of distribution. Every one of them are defective in many particulars. Sauvage, Vogel, Linnæus, Dr Cullen, have each adopted peculiar theories of particular diseases. These theories constitute the basis of their different classifications. A person, therefore, who is not previously acquainted with these theories will naturally be surprised to find some diseases arranged under certain classes and orders. For example, who would expect to find a diarrhoea ranked under the class of Neuroses, and in the order of Spasmi, without knowing Dr Cullen's particular theory concerning the cause of that disease? The generic characters of many diseases will likewise be totally unintelligible to such a person.

However, notwithstanding these defects arising from the theoretical distribution of diseases, we cannot hesitate a moment in preferring even a bad method of classing to none at all. Every attempt towards a just and natural arrangement of diseases is laudable, and has a direct tendency to introduce science into the medical art; an object greatly to be wished for, but which still appears to be very distant. There is, however, a danger attending attempts of this kind which deserves to be pointed out. In every art which is not founded upon known facts and established principles, new projects are eagerly grasped at; and, though they lead to error and false reasoning, it is long before the professors of that art can be induced to give over the pursuit. This observation is peculiarly applicable to medicine. The theories of diseases, as well as the mode of prescription, are as variable as the fashions of a lady's head-dresses. No other argument is necessary to shew the crude state of the art, and the boundless field for improvement. Now, the great danger arising from the classing of diseases is this:—It will divide physicians, in the first place, into two great parties: the one party will spend much time and genius in shewing the uselessness of classing in general, and particularly in the present imperfect state of the art; the other will imitate their example in defending with equal keenness. Nay, what is still worse, every professor belonging to this last party, besides spending much time to little purpose in justifying classification in general, will consume still more time in criticisms upon every other mode of classing besides the one he chuses to adopt. Now, this bustle about classification among the teachers of medicine, will naturally lead the minds of unexperienced students to conclude, that the whole science consists in a particular arrangement of diseases, and that they cannot make a more proper display of their medical knowledge, than by discovering an acquaintance with all the various methods of classification, and an acuteness in criticising all the other methods but that particular one which he has been taught to believe as infallible.

Having thus given a short account of the origin and present state of physic, we shall now proceed to the history and treatment of diseases.

Of FEVERS in general.

Hoffman defines a fever to be, "A spasmodic affection of the whole nervous and vascular system, annoying all the functions of the body, arising from any cause which has power to irritate the nervous parts to a more intense contraction; and when it operates, it drives the vital fluids from the outward parts to the heart and great vessels; and afterwards, when the systole of the heart and arteries are increased, they are driven back with rapidity and heat, through the contracted vessels, to the outward parts again, till the spasms being relaxed, the secretions are performed, and the fever vanishes."

The formal or fundamental cause of a fever consists in the spasmodic affection of the whole nervous and fibrous genus. This plainly appears from the usual phenomena of a fever, *viz.* a pain in the back, more particularly about the loins; a coldness, especially of the extreme parts; a shivering, shaking, trembling; a livid colour of the nails; a subsidence of the vessels of the hands and feet; a shrunk, dry skin; a yawning; a stretching; a pale, livid countenance; a trembling and palpitating motion of the heart; an anxiety of the præcordia, difficult breathing, inquietude, restlessness; a sensation of an ebullition of the blood about the heart; a contracted, weak, small pulse; a nausea, and an inclination to vomit; a suppression of perspiration; coldness, with thin watery urine.

Hence it naturally follows, that whatever has a power to irritate and solicit the nervous and vascular system to spasms, is most likely to generate a fever. To this class belong violent passions of the mind, especially terror and anger; a poisonous, subtle, caustic matter, either bred within the body, or received by infection; a stoppage of perspiration; a suppression of critical sweats; eruptions driven back; an abundance of purulent ulcerous matter adhering to various parts; aliments too acrid and sharp; corrupt and bilious crudities lodged in the primæ viæ; excessive watching; a violent pain and tension of the nervous parts; inflammations, tumours, and abscesses; hurting the nervous parts by sharp instruments; acrid and corrosive drugs; cold baths, and, on the contrary, those that are too hot or astringent.

According to the different nature of these causes, and the various manner of affecting the nerves, arise fevers of divers kinds. Some are benign, others malignant; some are intermitting, others continual; some are simple, others compound; others regular or anomalous; eruptive, spotted, putrid, hectic, or slow. Some admit of an easy cure, others a difficult; some soon terminate, others are protracted a long time; and many hurry the patient suddenly out of the world.

Yet, every frequent systole of the heart and arteries discoverable by the pulse ought not to be called a fever. For these may often arise from violent bodily exercise; or, from a commotion in the blood caused by hot and spirituous liquors. That only which arises from internal causes, and is preceded by shivering, shaking, and cold-

ness of the extreme parts, is properly a fever: For there is always, as it were, a double motion in a fever; the one from the circumference to the centre, or from the external parts to the internal, the heart and lungs; the other from the centre to the circumference. The first motion is attended with a small, contracted, weak, pulse, with an anxiety of the præcordia and difficulty of breathing; the second with an increased motion of the arteries, a large pulse, and heat extended even to the extreme parts.

The cause of the febrile motion is an universal spasm; and that motion never ceases till the spasm is resolved. The signs of its being resolved are, a free perspiration, and a breathing sweat; the pulse, which before was hard, impetuous, and quick, becomes soft, moderate, and slow; the urine lets fall a sediment, and the strength gradually returns. When these appear all together, they declare the solution of the disease, and are called the crisis.

OF INTERMITTING FEVERS, or AGUES.

This fever is of the regular kind, and is attended with the following symptoms. At first, the head aches, the limbs seem weary; there is a pain in the loins about the first vertebra of the back, which ascends towards the epigastrium, with a painful sense of a tension in the hypochondria, and costiveness: then comes on a coldness of the external parts, especially of the nose and ears; a stretching, yawning; a shivering and shaking, sometimes even to make the bed tremble under the patient; the pulse is small, contracted, and weak: again the patient is troubled with thirst; then follows a nausea, with a fruitless reaching to vomit; again, a pituitous, bilious, or green matter is brought up, commonly joined with a troublesome cough, and an expectoration of phlegm derived from the acid clammy crudities of the stomach; to these succeeds an anxious burning and dry heat, which pervades the whole body. The face, which was collapsed and pale, the contracted, rigid skin, and the empty vessels of the hands and feet, begin to rise, and grow red and turgid; the pulse becomes more great, full, and quick; the restlessness increases, the breathing is more difficult, and the patient, with his eyes almost closed, begins to talk a little wildly.

Afterwards, the symptoms begin to abate, the heat becomes mild, the skin relaxes and grows moist; the urine is of a flame colour, but without a sediment; the pulse is more moderate; and then a sweat breaking out, terminates the paroxysm. The duration of the fit is uncertain; sometimes it ends in ten or eleven hours, and sometimes not till twenty-four. On the intercalary day, the body is still feeble and coldish, with a disposition to shiver; the pulse is slow and weak; the urine is turbid, and deposits a sediment, or there is a nubecula which shews a disposition thereto.

In the **BASTARD or SPURIOUS TERTIAN**, the symptoms are milder, the heat is not so burning, the vomiting is not so frequent, and the urine is not so high-coloured; but then it is a more lingering complaint, and on the well day there is a lassitude and want of appetite. This attacks men of an inactive disposition, and women whose bodies are of a loose texture, in the autumnal season.

The fit of the **IRREGULAR TERTIAN** observes no

particular time; for it sometimes comes on in the morning, sometimes in the afternoon, in the evening, or at midnight. The paroxysm is sometimes longer, sometimes shorter; the urine lets fall no sediment within the time of remission or intermission; the sweating is either too sparing or too profuse. When the fit is off, several unusual symptoms may appear; as, a looseness, a bleeding at the nose, sickness at the stomach, a violent heartburn, pains in the belly, or the gripes. These sort of agues are generally **ENDEMIC**, and most commonly appear in the summer and autumn.

Sometimes a tertian ague is **DOUBLE**, which may be distinguished from a quotidian, by the time of the fits, which is not the same every day, but every other day.

There is sometimes a **CONTINUAL TERTIAN**, which begins with shivering and shaking, an anxiety, vomiting, loss of strength, and then a violent heat. The fits do not intermit, but only remit. The pulse continues frequent with heat and debility, and all the symptoms return with fresh vigour every other day; but at length admit a perfect intermission.

An **ENDEMIC TERTIAN** is proper to certain places; as a low situation, and full of marshes, producing a great number of gnats and other insects, like some parts of Kent, and the hundreds of Essex. In such places, the natives themselves have a little of it every year; and strangers seldom or never escape, without a preservative, which is only the bark infused in brandy, with a little snake-root, of which two ounces night and morning are to be taken.

A **QUARTAN AGUE** has two fits in four days, or two days quite free from a fit.

It begins about four or five in the afternoon, sometimes sooner and sometimes later, with a great lassitude, stretching, a blunt pain in the head, back, loins and legs; the feet and hands are cold; the whole body is pale; the face and nails livid, to which shivering and shaking supervene. The tongue and the lips tremble, the breathing is difficult, with restlessness and tossing; the pulse is contracted and hard, and sometimes unequal; and there is an anxiety about the præcordia. These symptoms continue about two or three hours. In some the body is costive; in others there is a stimulus to stool, and to make water. In some there is a nausea or vomiting, with stools. Some advanced in years have their minds pretty much disturbed; the heat comes on gradually, not burning but dry; the pulse becomes equal, quick, and large; but the dull pain in the head remains, with a vertiginous affection; the skin becomes only a little moist; and in about four or six hours the symptoms vanish, except a dull pain in the bones, joints and feet. The urine in the fits is sometimes thin and watery, sometimes thick and with a sediment.

Sometimes a quartan ague is **DOUBLE**, that is, when the fits come on every other day at different hours; and it is **SPURIOUS** when a paroxysm begins at any other time of the day but that above-mentioned. It is said to be **CONTINUAL**, when on the intercalary days there are shiverings and pandiculations, with a greater heat than usual, a quicker pulse, a want of appetite, a debility, a dryness of the mouth, a lightness of the head, a distur-

† Q ed

ed sleep, and a reddish urine, with a thick rose-coloured sediment.

A QUOTIDIAN AGUE or fever returns every day, and is not so common as the tertian or quartan.

The accession of this fever is about four or five in the morning, with cold and shivering; to which succeeds a cardialgic nausea, and inflation of the belly; in some, a pain in the head; in others, fainting fits; in most, vomiting or stools, or both. Then comes on a moderate heat, with thirst, but not very intense. The pulse, which was before irregular and weak, becomes more quick, but not very hard. The urine is not of a flame but rather of a citron colour, and turbid. Some are exceeding sleepy. At length a moderate sleep supervenes; and in about ten hours or longer, the fit goes off, leaving the body dull and heavy.

From these symptoms it appears, that the whole nervous system is agitated and suffers greatly by spastic contractions; which proceeding chiefly from the medulla spinalis, affect preternaturally not only the coats of the vessels, but all the fibres throughout the body, thereby greatly disturbing the motion both of the solids and fluids.

The material cause of this, and all other fevers, according to Hoffman, is a fluid of an active nature, endued with a caustic acrimony, which solicits the internal and exquisitely sensible parts to spastic contractions. It is generated chiefly in the biliary ducts and flexures of the duodenum; where the vitiated, bilious salival and pancreatic juices meeting with the crudities of a bad digestion, ferment together, and, not being timely expelled, become virulent. This matter passing through the lacteals, into the blood, and thence into the nervous parts of the head, medulla spinalis, intestines, and stomach, as also to the nervous coats of the excretory and secretory ducts, excite an universal spasm, which first forces the blood to the interior and greater vessels; and afterwards the systolic motion of the heart and arteries being increased, the motion of the whole mass of blood and humours is accelerated, and the obstructions of the small vessels of the nervous parts are opened; upon which the spasm ceasing, the excretory ducts are relaxed, the febrile matter passes off through the pores of the skin by perspiration or sweat, and the fit ceases, till by the generation of fresh matter a new paroxysm is brought on.

As to the cure, when a load of vitiated humours in the stomach and duodenum require depletion, which is known from having indulged in too plentiful eating, from an anxiety of the præcordia, from eructations, and a bitter taste in the mouth, a vomit, after the first fit, in the time of intermission, is to be given. In tender constitutions, 10 grains of ipecacuanha may be given alone; but to the more robust, a grain or two of emetic tartar may be added. Or if it is necessary to purge at the same time,

1. Take half an ounce of Epsom salt, and two or three grains of emetic tartar. Mix them and make them into a powder; to be dissolved in a pound of pure lukewarm water, and taken two hours after the fit.

The evacuation ought to be facilitated with draughts of water-gruel made fat with fresh butter. Then take the

following electuary, which will crush the disease in the bud.

2. Rob of elder, one ounce; 5 drams of Peruvian bark; 2 drams of chamomile flowers in powder; extract of the lesser centaury, and powder of jelliflowers, of each half a dram; add as much syrup of lemon as will make an electuary. Half a dram to be taken every two hours, after the fit has gone off.

But if any thing forbids vomiting, and yet there is plenty of ferous crude humours which require evacuation, we must begin the cure with detergent and aperient salts.

When the whole intestinal canal has been cleaned by these salts, duly repeated at proper intervals, and the ague still continues, add an equal weight of bark thereto, or give the electuary above prescribed.

When the patient is obnoxious to the hypochondriac passion, the stomach inflated, and the body colicive, neither vomits nor salts must be ventured upon, but carminative and emollient clysters.

But it must be remembered, that neither bleeding, nor emetics, nor cathartics, nor the bark, nor any strengthener nor astringent is to be administered or given in the fit, or near the time it usually comes on.

If a tertian is autumnal, oblique, or changes to a quotidian, the antifebrile potion of Crollius will be proper.

3. Salt of wormwood, a dram; spirit of sulphur, a scruple; 4 ounces of fennel water. Mix them together for a drink.

Let the patient take it just as the fit comes on, and be well covered with bed-cloaths.

Bleeding is proper only in a hot season, when the heat of the patient is excessive, attended with a delirium, and in the prime of life, full of blood, and subject to passion.

Opiates will appease the symptoms; but they disturb the crisis, and protract the disease. Likewise aluminous, chalybeate, and vitriolic remedies will stop the fits; and if they are given to patients of the lowest class, care must be taken that they sweat after them, by drinking hot decoctions, or by exercise.

Absorbents have often a happy effect in these diseases; but if given in too great a quantity, they will not dissolve in the stomach. Harris advises 2 scruples of the simple powder of crabs claws, two hours before the fit, and to be repeated in an hour, in mint-water; no small beer is to be drank for eight hours after. It may be repeated in the same manner against the next time the fit is expected; as likewise a third time.

Langrish asserts, that in long continued agues or intermitting fevers, which have baffled the bark and many other medicines, he has met with more advantage from rhubarb and calomel exhibited in small doses, than from any thing else he had tried.

To prevent the return of an ague, the bark must be repeated every week or ten days, for three several times, with the same intervals. Likewise bitters and chalybeates are very serviceable for the same purpose.

Of the CATARRHAL FEVER, or the Continual Quotidian of the ancients.

It generally begins in the evening, with a shivering and

and a coldness of the extreme parts, especially of the feet, and soles of the feet; a coldness; a frequent desire of making water, but the urine is small in quantity; a weakness of the head, an universal languor of the whole body, a false appetite, thirst, difficulty of swallowing, a stimulus in the larynx; a heat in the nostrils and fauces, attended with sneezing; a weight in the breast: towards night, heat, and a quicker, fuller pulse, with a defluxion of rheum, a heat in the fauces, unquiet sleep, a sweating in the morning, a heaviness and dulness of the whole body, and a loss of appetite.

The immediate cause of this disorder is a sharp acid serum or lymph, subsisting in the glandulous tunics, and irritating them with pain, tumour, and redness. This happens in the whole region of the nostrils, palate, and fauces; as also in the aspera arteria, with the bronchial branches; and farther in the oesophagus, stomach, and intestines. Hence a hoarseness, a cough, a hawking up of viscid matter, a sneezing, a defluxion of the lungs: likewise a nausea, sometimes a vomiting; a heat about the præcordia; a griping of the guts, followed with a salutary flux.

It more frequently attacks women and children than men, and those that indulge themselves in strong liquors. It sometimes happens from the drying up of a scald head and other eruptions. Sometimes it is epidemical.

This disease is most frequent in the spring and autumn, in sudden changes of the weather from hot to cold, from dry to moist, and *vice versa*; as also from change of air, if of different qualities; from being exposed to the cold air of the night, and from throwing off winter-garments too soon.

This disease is not dangerous in itself, if rightly managed, and terminates in seven or fourteen days at farthest: for the lassitude of the body then disappears; and the other complaints, especially the head-ach and hemi-crania are appeased, when the catarrh appears, and there is a plentiful discharge from the nostrils.

It often goes off, in some, in the beginning, with an increased perspiration or by sweat; in others after a few days, by hawking up a large quantity of viscid matter, or a plentiful discharge of a mucous serum by the nose; in others, by a looseness, when the urine at the same time, which before was thin and little, becomes copious and heavy, with twice the quantity of sediment as in a natural state.

The intentions of cure are three, 1. To sheath the acrimony of the lymph. 2. To increase perspiration. 3. To promote the expectoration of the viscid mucus.

The saline sharpness of the lymph may be taken off by the absorbent and diaphoretic powders, humecting and oleous remedies; such as, oil of sweet almonds, spermaceti, milk, cream, almond emulsions, with the addition of white poppy seeds, barley broth, water-gruel, chicken broth, with the yolk of an egg; as also liquorice-juice, liquorice tea, dried figs and raisins. If the acrimony is very subtle and corroding, gentle anodynes should take place, such as saffron, diacodium, and storax pills.

To promote a diaphoresis,

1. Take a scruple of the powder of contrayerva; Vir-

ginian snake-root and saffron, of each 5 grains. Mix and make them into a powder. To be repeated in 4 or 6 hours, if necessary.

To appease the cough,

2. Take oil of olives, an ounce and a half; pure water, 6 ounces; spirit of hartshorn, 40 drops; pectoral syrup, one ounce. Mix them, and take a spoonful every four hours.

To promote perspiration, order tea, with leaves of veronica, hyssop, liquorice-root, elder flowers, wild poppies, and fennel seeds; as also the more fixed diaphoretic powders, with antispasmodic waters; but especially bodily motion and exercise.

To promote the excretion of the thick, viscid mucus, figs and raisins are proper, with brandy burnt, and reduced almost into a syrup. Likewise a pectoral elixir, made of gum ammoniac, myrrh, liquorice-root, elecampane-root, saffron, benjamin, and oil of aniseed, whose virtue may be heightened by the vinous spirit of sal ammoniac or tincture of tartar. The stagnating mucus of the nose may be dissolved by often holding to the nose the dry volatile sal ammoniac, mixed with a few drops of genuine oil of marjoram.

The regimen should be temperate; and cooling things, as well as acids, should be avoided.

The aliment should be sparing, the drink warm and wholesome; the best is a decoction of pearl-barley and shavings of hartshorn, as also water-gruel.

If the body is collic; besides water-gruel, manna, prunes, and raisins, nothing is better than an emollient clyster.

In the decline of the disease; when the cough is too moist, the defluxion great and obdurate, it will be proper to take a large dose of manna, to two or three ounces in fennel-water, to carry the humours downward.

When the cough is very violent, it must be appeased with a mixture of oil of sweet almonds fresh drawn, and French syrup of capillaire.

When women labour under a suppression of the menses, the body must be kept open with clysters; bezoardic powders must be given, and a grain of saffron added to each dose, or a few grains of flowers of sulphur; but avoid sweet things and expectorants.

When the fever is vanquished, and the lungs continue in a lax state, which is known from too large a spitting, to the bezoardic powders must be added a few grains of cortex elutheria.

In a violent obdurate cough, sweet pectorals, and in-crustating-remedies too plentifully given, bring on a cachexy, or phthisis, by spoiling the appetite, and hurting the tone of the lungs. HOFFMAN.

What we commonly call CATCHING COLD, may be cured by lying much in bed; by drinking plentifully of warm sack-whey, with a few drops of spirit of hartshorn, pepper-drink, water-gruel, or any other warm small liquor; living upon spoon-meats, pudding, and chicken, and drinking every thing warm: In a word, treat it at first as a small fever, with gentle diaphoretics; and afterwards, if any cough or spitting should remain, by softening the breast with a little sugar-candy and oil of sweet almonds, or a solution of gum ammoniac in an ounce of barley-

barley-water to make the expectoration easy, and afterwards going into the air well clothed.

Of the SEMITERTIAN FEVER.

THIS is an epidemic fever, compounded of an intermitting tertian and a continual quotidian.

It generally makes its onset before noon, with coldness, shaking, and a contracted pulse; to which succeeds a frequent pulse, with heat, which continues some hours, till a warm sweat appears, without a complete intermission. The heat, after a slight coldness, increases towards night, with a quick pulse; which is more moderate the next day, without thirst, till the evening, when a slight shivering comes on, and the symptoms return. On the third day, the shaking fit appears again with more intense heat, and proceeds in the same track as before; so that the fever is never quite off, but has an exacerbation in the evening: however, the shaking fit is most conspicuous every third day in the morning.

Besides the foregoing symptoms, the strength fails, the appetite is languid, sleep is wanting, the urine is thin and crude; but after the fit on the third day, it is thick and coloured, and a small quantity of crude matter is brought up with coughing. It is sometimes attended with a pain in the back and the abdomen, together with a swelling in the latter. Some at the access of the fit of the tertian, are affected with a nausea and cardialgia. Some vomit, others faint, and others again are delirious.

This fever is generated by all things that render the humours thick and impure, especially those that fill the prime viæ, and the vessels of the mesentery, with impurities. Those are most liable to it who live upon sweet, acid, and fermentable aliment, that live an idle sedentary life, that drink less than they ought, or love sweet wines; as also those that give way to sadness and melancholy.

It generally terminates either on the ninth or thirteenth day, in health, or another disease, or death.

It is a good sign when a sweat breaks out at the decline of the paroxysm, and when, on the seventh day, being critical, or, after it, the belly is disturbed, and is followed with a flux of a bilious, pituitous, or bloody matter, for it foretells the solution of the disease; as also when the pains in the belly are very sharp, and grow worse at certain hours, being followed with a sanious and purulent diarrhoea, or when plenty of black blood comes away.

It is a bad sign, when nothing of this happens: but, on the other hand, a heat about the præcordia, a tension and pain in the whole region of the stomach, a vomiting and hiccup, inquietude, tossing and trembling of the hands, are very ominous, and shew that the inflammation has reached the stomach.

The cure is to be performed, 1. By speedily dissolving the inflammatory stasis in the coats of the intestines and mesentery, and preventing it from spreading farther. 2. By correcting and gently evacuating the matter of the intermitting fever.

The first end may be obtained by diaphoretic powders, mixed with a little nitre, in small doses, but taken often.

Take of scorzonera root, 2 ounces; shavings of

hartshorn, and psallara, minor. of each one ounce; of chichory root, half an ounce. Boil the ingredients for half an hour in 8 pounds of water.

To cleanse the first passages, and to carry off the morbid matter, use a solution of manna with cream of tartar, raisins, and a little sal polychrest.

Things of this kind cleanse the intestinal canal, without raising a commotion in the blood, without stimulating the nervous parts, and without sinking the spirits.

Purges in the beginning are unsafe, because the morbid matter is not prepared; but if the body is costive, it may be opened with an emollient and saponaceous clyster.

All detergent salts are improper in this disease, except stibiated nitre and sal polychrest; for these have an aperient, diuretic and laxative virtue, and may be given to 15 grains in a proper vehicle. When this fever is on the decline, and nature seems intent in carrying off the disease by stool, then the above laxative will be proper.

Bleeding will be proper in the very beginning of the disease, if the patient is plethoric, the heat urgent, the strength not much impaired, and when some critical hæmorrhage is suppressed. All heating medicines are to be avoided, as well as fixt astringent earthy terrefactive powders; and also the bark, unless there is a perfect intermission; for this last, as Baglivi observes, has brought on fatal inflammations, or slow hectic fevers.

Of the NERVOUS FEVER.

IN a nervous fever, the patients at first are subject to slight transient chilliness often in a day, with uncertain flushings of heat; they have a listlessness, lassitude, and weariness; they are apt to sigh, and complain of a heaviness, dejection, and anxiety, with a load, pain, or giddiness of the head, with an inclination to yawn and doze; they want appetite, and dislike every thing; they have a dryness of the lips and tongue without any considerable thirst; they have frequent nausea's, with reaching to vomit: the breathing is difficult by intervals, and especially towards night there is an exacerbation of the symptoms, with a low, quick, unequal pulse; the urine is pale, and made often and suddenly; a torpor, or obtuse pain and coldness often affect the hind-part of the head, or a heavy pain is felt along the coronary suture. These commonly precede some degree of a delirium.

The countenance is heavy, pale, and dejected: sometimes they are quite wakeful; and when they fall asleep, they are so insensible of it, that they disown it.

The pulse is very remarkable in this disease, and requires the most diligent attention; for it is generally low, quick, and unequal: the inequality consists in this, that a few pulsations shall be more swift, frequent, and large, sometimes fluttering; and then presently it returns to be low and quick.

The urine has generally no sediment; and when it has, it is like bran: it is sometimes of a whey-colour, or like dead small-beer. The dryness of the tongue seldom appears at the beginning, though it is then sometimes covered with a thin whitish mucus; but at the close of the disease, it often appears very dry, red, and chapped.

About the seventh or eighth day the giddiness, pain, or heaviness of the head, become much greater, with a constant

fant noise in it, or tingling of the ears, which is frequently the forerunner of a delirium.

The load on the præcordia, the anxiety and faintness, grow much more urgent; and the patient often falls into an actual deliquium, especially if he attempts to sit up. Now, cold sweats appear suddenly on the forehead and back of the hands, while the cheeks and palms glow with heat, and as suddenly go off. If the urine grows more pale and limpid, a delirium is certainly at hand, with universal tremors and *subultus tendinum*; the delirium is generally little more than a confusion of thought and action, a continual muttering and faltering of speech. Sometimes they awake in a hurry and confusion, and presently recollect themselves, but forthwith fall into a muttering, then doze again.

At the state, the tongue grows often dry, with a yel low lift on each side; and when the patient attempts to put it out, it trembles greatly. If at this time a copious spitting comes on, it is a very good sign. When there is a difficulty of swallowing or continual gulping, it is a dangerous symptom, especially with a hiccup.

On the ninth, tenth, or twelfth day, the patient often falls into profuse sweats, which at the extremities are commonly cold and clammy; and frequently there are thin stools, which are generally both colliquative and very weakening. A warm moisture on the skin is reckoned salutary; and a gentle diarrhoea often carries off the delirium and sleepiness.

When the extremities grow cold, the nails livid, the pulse exceeding weak and quick, inasmuch that it rather trembles and flutters than beats, or creeps surprisingly slow, with frequent intermissions; then nature sinks apace, and the patient becomes quite insensible and stupid; the delirium turns to a profound coma, which soon ends in death; or the stools, urine, and tears, run off involuntarily, as a prelude to a speedy dissolution; or there are vast tremblings and twitchings of the nerves and tendons, which terminate in a general convulsion, and this in a cessation of all motion. One or other of these ways closes the scene, after the patient has languished fourteen, eighteen, or twenty days, nay, sometimes much longer.

All persons grow deaf and stupid towards the end of the disease, and if the deafness ends in an impollubum of the ear, or when a *parotis* suppurates, or a large pustular eruption breaks out about the lips and nose, they are good symptoms.

The cure is to be performed with gentle medicines of the cordial and diaphoretic kind, in order to promote perspiration; by application of blisters, and by a proper regimen and method of diet. It will bear no other evacuation than moderate cordial diaphoretics, and blisters; unless a gentle emetic should be indicated in the beginning, or a small dose of rhubarb when it has continued long. Bleeding is very prejudicial, and much sweating hurtful. In giving diaphoretics, we should always have regard to the urine; for if that, from being pale, gradually heightens to an amber colour, we are right in our dose, especially if, when in bed, a gentle dew or moisture comes on without a restlessness, and we must always remember, that over sweating will raise the fever, and endanger the patient.

If the patient is inclinable to deliquia or faintings on

every little motion, or complains of greater lassitude or faintness than ordinary, it will be necessary that he lie in bed and have blisters applied; if delirious, the blisters must be laid on high on the nape of the neck.

If rest is wanted, give a few grains of the *flores martiales*; and if a looseness is not feared, the *flores martiales* may be more freely given.

A vomit ruffles nature much less than a common purge, and is necessary where a nausea, load, and sickness of the stomach, are urgent. If the body is costive, clysters of milk, sugar, and salt, may be injected with safety and advantage every second or third day. The temperate cordial and diaphoretic medicines are certainly most proper in these fevers; a supporting, well regulated, diluting diet is necessary, and will go a great way in the cure, especially if assisted by well timed blisters, and keeping the patient quiet in body and mind. Opiates are commonly very pernicious; mild diaphoretics, as *pulv. contrayerv.* compos. with a little castor and saffron, and small quantities of *theriac. androm.* or *elixir paraceticum*, will have much better effects. Where the confusion or dejection of spirits are considerable, galbanum or silyphum, with a little camphire, should be added; and blisters should be forthwith applied to the neck, occiput, and behind the ears: during all this, a free use of thin wine whey, some pleasant ptisan, with a little soft wine, must be indulged. A little chicken-broth also is of service, both as food and physic, especially towards the decline of the disorder; and for the same reason, thin jellies of hartshorn, sago, and panada, are useful, adding a little wine to them, with juice of Seville oranges or lemons.

It was said above, that profuse sweats should never be encouraged; yet the patient is never so easy as while he is in a gentle, easy sweat, for it soon removes the exacerbation of the heat, hurry, &c. when there are irregular partial heats, with great anxiety, restlessness, delirium, difficulty of breathing, and a vast load and oppression on the præcordia, so as to resemble a peripneumonic case: yet beware of bleeding; for the small, low, quick, and unequal pulse utterly forbids it, as well as pale, watery, limpid urine.

Here then the nervous cordial medicines are indicated, and blisters to the thighs, legs, and arms.

Take of the compound powder of contrayerva, 15 grains; of English saffron, 3 grains; a scruple of the cardiac confection; and a sufficient quantity of Syrup of saffron to make a bolus.

When great tremors and *subultus tendinum* come on, instead of the *pulvis contrayerva*, a scruple of mulek may be used.

This bolus should be taken every fifth, sixth, or eighth hour, and a temperate cordial julep may be given now and then out of thin wine or cyder-whey, or, which in many cases is better, out of thin mustard-whey.

But this difficulty of breathing, anxiety, and oppression of the præcordia, often precede a miliary eruption on the seventh, ninth, or eleventh day, which should be promoted by soft, easy cordials, proper diluents, sometimes with a little *theriac. androm.* or *elixir asstima*, as tending to calm the uneasiness, and to promote a diaphoresis.

In profuse, colliquative sweats, give a little generous

red wine, perhaps a little diluted, which moderates the sweat, supports the patient, and keeps up the miliary papillæ.

Towards the decline of the fever, when the sweats are copious and weakening, give small doses of the tincture of the bark, with saffron and snake-root, interposing now and then a dose of rhubarb, to carry off the putrid colicives, which makes the intermissions or remissions more distinct and manifest.

When there is an evident intermission, give preparations of the bark out of draughts made with salt of wormwood and juice of lemon. This method will shorten these fevers, even with miliary eruptions.

Under any evacuations, diluting nourishment is absolutely necessary to keep up the spirits and repair the loss of the juices, and the patient should be frequently prompted to take them. When any discharges are very immoderate, they may be prudently restrained, but not repelled.

Gilchrist affirms, that to all the warming, attenuating, stimulating, or antispasmodic remedies, cinnamon should be added, and that in no small quantity. And he highly recommends the use of the bark in the decline of long nervous fevers, or after a remission. And when there is occasion for blistering, he thinks the head most preferable whenever it is much affected, though he does not disapprove the laying blisters on the back and limbs.

When the low, depressing, nervous symptoms are stronger, the higher methods of stimulating are more necessary and easily borne; in raving, with a low, intermitting pulse, subsultus, fainting, and coldness of the extremities, besides frequent blistering, we must give camphire and castor. The uses of Virginian snake-root, valerian, asa fœtida, myrrh, and terreous absorbents, are well enough known, and the forms in which they are given. Refreshing juleps should not be taken by spoonfuls, but by draughts. Acrid cataplasms may be laid to the feet till they begin to stimulate or raise a just degree of heat: then apply poultices of bread, milk, and vinegar, especially during the exacerbation, to allay the heat and struggle; renewing them alternately, in order to keep up a gentle heat and stimulus. A quick, hard, and more contracted pulse, with smart heat, tossing and anxiety, shew it is over-done.

O/Epidemic, Catarrhal, Eruptive FEVERS.

These fevers are continual, but not violent: they are attended with a prostration of strength, watching, loss of appetite, and are sometimes joined with an eruption of spots on the skin, arising from the plenty and intestine dissolution of an excrementitious serum, not without contagion and danger of life.

These fevers were called by the ancients, *continual, quotidian, serous fevers*; and by some of the moderns, *malignant catarrhal fevers*, because they are mild at first, and attended with a running at the nose, a catarrh, an infarction of the breast, and a cough on the first days, with exacerbations at night.

At the beginning of this disease, the face of the patient has a morbid aspect, and he is out of order three or four days before he takes to his bed. He complains of a spon-

taneous weariness, a grievous pain of his body and joints, as if his bones were bruised and broken; his strength is languid, his appetite is lost, he has a slight fainting fit, a cardialgic nausea, a pain in the head, an inquiet sleep, with costiveness. In the evening there is a coldness and shivering followed by heat, the symptoms increase, and there is a greater loss of strength, inasmuch that he can scarce stand upright. The pain in the head grows worse, with a giddiness and inquietude. Some have a violent pain in the back, others in the side: they have an anxiety about the præcordia, the internal parts are hot, the fauces dry, the pulse contracted, quick and weak, the urine is pale without a sediment, and the breathing difficult.

On the fourth or eleventh day, spots appear on some, chiefly on the back, breast, and arms, with or without relief. Some have more, some less, of various colours, as purple, a brownish, livid, or a pale rose. These are sometimes broad, sometimes small; and in many like fleabites. These different spots serve to distinguish the fever by several names, such as miliary, puncticular, bastard petechial, and the like.

When this disease is at its state, or vigor, all the symptoms are worse; the inquietude runs very high, as well as the tossing of the body with unusual postures. The mind is disturbed, the speech incoherent, sleep wanting, the sweat is coldish, with a more intense difficulty of breathing, and a contracted, unequal, quick and frequent pulse, as in the nervous fever.

When a subsultus tendinum, want of thirst, rumbling in the belly, hiccup, an inflammation of the fauces from aphthæ, convulsions, a syncope, with coldness of the extremities, and a most plentiful sweat, supervene to these symptoms, they are certain forerunners of death. On the other hand, when a sweat breaks out about or on the critical days, that is, the seventh, eleventh, or fourteenth day, and continues several days, though want of strength remains; or if there is a looseness for some days, it is a sign of health; and this the more certain, if the contracted pulse enlarges, the hard grows soft and becomes more equal; if the patient is more cheerful, and his lying in bed more sedate, with a hardness of hearing, and a turbid urine depositing a sediment. If this happens about the critical days, it is a certain sign of a happy event. After this the sleep, appetite, and strength, gradually return; but this is seldom the case before the fourteenth day.

Patients of a strong constitution, the common people, and rustics, with a good regimen alone, generally succeed better than the weak, the timorous, the sad, the thoughtful, the luxurious, the slothful, and the studious. All excretions by urine, stool, or sweat, are bad in the beginning, and on other days except the critical. Those that die are carried off by a palsy, or an inflammation of the meninges, or of the œsophagus, and fauces from aphthæ of the stomach itself. If blood is taken away in these diseases, it is either of a bright red, very fluid and serous, or too thick and blackish.

In the cure of this disease, the physician should take care not to disturb the salutary excretions, but proceed cautiously, and abstain from strong medicines of every kind, watching and assisting the motions of nature as much as possible. The indications are, 1. To restrain and pre-

vent the entire dissolution of the blood and humours. 2. To temperate and dilute the salino-sulphureous acrimony of the humours, and at the same time to keep the fluids fluxile. 3. To promote gently the excretions by stool, urine, the skin, and spittle. 4. To assist and restore the lost strength.

To prevent the putrid dissolution of the humours, direct vinegar, the juices of oranges and lemons, and syrups of the same; spirit of vitriol, spirit of salt, spirit of nitre, especially those that are dulcified.

To abate the acrimony, absorbent, testaceous, and bezoardic powders will be proper. To dilute at the same time, you may order a decoction of barley with scorzonera and shavings of hartshorn; as also the syrup of orange-juice, chicken broth, and the like.

To promote the cuticular excretions, give diaphoretic simple waters, alexiterial waters, with the tincture of valerian root, or snake root. To assist the excretions by stool, common domestic clysters will be useful; or those made of a decoction of barley, oil of sweet almonds, camomile flowers, elder flowers, syrup of violets, common salt, or nitre.

Or you may order the following laxative, which must be given with caution.

Take 2 ounces of manna, a dram of cream of tartar, 3 ounces of scorzonera water, half an ounce of syrup of violets, 3 drops of oil of juniper. Mix and make them into a draught.

To raise the spirits and restore the strength, a little wine will not be improper, with hartshorn jellies, China orange or Seville orange juice with sugar.

A congruous regimen in these diseases is of very great consequence; for if the patient is kept too hot, the dissolution of the blood will be promoted, a costiveness will be induced, the anxiety will be increased, the impure salt and acid humours will be actuated, the strength will be exhausted, the sweating will be too speedy and profuse, and spots will appear on the skin. On the other hand, if cold is incautiously admitted, especially to the feet, perspiration will be checked, the eruptions and spots will be driven back: There will be gripping pains, a looseness, and the critical evacuations will be disturbed. All sudden changes from hot to cold, or cold to hot, are equally bad. A temperate regimen is best. However, care should be taken that the patient does not breathe his own atmosphere full of morbid exhalations, so very prejudicial to health; but the air should be drawn out of the room, and fresh admitted.

The perspiration should constantly be kept up, and the linen of any kind should not rashly be changed, nor should the patient be removed from one bed to another. He should be enjoined not to rise frequently. And if the bed-cloaths are wet and must needs be changed, let them be well-aired, and pretty much worn.

An erect posture of the head and body is to be shunned either in or out of bed, especially if the pulse is very weak and the strength little; as also when the disease is near the state

The mind should be kept as cheerful as possible, and all occasions shunned of exciting anger, fear, terror, or pusillanimity in the patient. His hope of recovery should

be kept up as much as possible, instead of being terrified with the prediction of death.

It is an undoubted axiom, that all strong medicines are hurtful in this disease; such as emetics, purgatives, and diuretics; as also sudorifics of too spirituous a nature: But temperate and moderate things are very useful.

It must be remembered likewise, that these fevers have certain types and periods, and exacerbations and remissions at certain times; which a physician should always carefully observe. In the freble heat, and when the symptoms are most intense, humectants, diluents, and the absorbent nitrous powders abovementioned will be most proper, with a very moderate external regimen. When the pyroxyfm is ended, the skin lax, more soft, and disposed for excretions; then analeptics, medicines that stimulate; and if there is occasion, bezoardics, and things that promote perspiration; as also the infusion of veronica, scordium, and liquorice, drank as tea, are likely to do the greatest service. And because a diarrhoea frequently carries off the disease, it is never to be stooped, especially about the critical times, neither with astringents, sedatives, or opiates: But if nature tends to this excretion, and is too sluggish, she is to be assisted by the laxative draught above described, with the addition of tamarinds.

There is no evacuation so dangerous as bleeding at the nose; for then there is a congelion of blood in the head from the spasms of the lower parts. However, if the flux of blood is moderate, and the body abounds with it, instead of being hurtful, it will relieve the head, though this seldom happens. When there are a few drops only without alleviation, they portend a delirium and an inflammation of the fauces: But when the flux is copious, the strength will diminish, and the eruptions return inwards not without danger. Therefore, to prevent a conflux of blood to the head, the feet must be always kept in a moderate heat and moisture; mild blisters should be laid to the calves of the legs, and the body should be opened with clysters or solutions of manna. These will also be serviceable when the hæmorrhage is too large. But when it is too little, and the eyes look red and wild, with a strong pulsation of the temporal arteries, besides the former, it will be proper to apply cupping glasses to the nape of the neck, or to thrust a straw up the nose to cause it to bleed, or to use a scarifying instrument.

Bleeding in these fevers must be used with great circumspection; for it is much more proper as a preservative than a cure. But when the disease has made its onset with great loss of strength, complicated with catarrhal disorders, and when putrid and malignant fevers are rife, it must be always omitted. If the stomach has lately been surfeited with incongruous aliment, a grain or two of tartar emetic in a solution of manna will be necessary. Blisters will be of great use when a retrocession of the eruptions is apprehended, when the excretions are slow, and when there is a sleepiness and torpor: in which cases, they may be laid to the arms and calves of the legs.

Of the Malignant, Goal, and Spotted Fevers.

THE true spotted fevers are very malignant, contagious, and detrimental to the head and strength, attended with spots of various colours, arising from a corruption

of the vital fluids, and a putrid dissolution consequent thereupon.

These petechial fevers are deserv'dly called malignant, or poisonous, as they generally proceed from a most subtle, active, virulent vapour, or miasma, which is infectious. At first they often seem mild and gentle, and have the appearance of catarrhal fevers; but they soon exert their virulent effects in a most fatal manner.

At first the patient complains of great weakness and loss of strength, and is apt to faint away.

The head aches, and from the very beginning is hot, dull, attended with a dejection of mind. There is constant watchfulness; the appetite is lost; the pulse is languid, small, and unequal; there is an oppression of the breast, sometimes a dry cough, an undulatory and tremulous twitching of the muscular and tendinous fibres, with a subulturn tendinum. Many neither complain of heat, nor pain, nor anxiety, and assert that they feel nothing bad, but weakness and want of sleep. The urine is generally thin at first, and like that of sound people. On the fourth, fifth, or the seventh day, the spots appear principally on the back and loins, of various colours, generally without relief; wherefore they are rather symptomatical than critical.

Huxham says, these fevers attack with much more violence than the slow and nervous; the rigors, if any, are greater, the heats sharper and more lasting, yet at first sudden, transient, and remittent; the pulse more tense or hard, but commonly quick and small, though sometimes slow and seemingly regular for a time, and then fluttering and unequal. The head-ach, giddiness, nausea, and vomiting, are much more considerable, even from the very beginning. Sometimes a severe fixed pain is felt in one or both temples, or over one or both eye-brows, frequently in the bottom of the orbit of the eyes. The eyes always appear very full, heavy, yellowish, and often a little inflamed. The countenance seems bloated, and more dead-coloured than usual. Commonly the temporal arteries throb much, and a tinnitus aurium is very troublesome; a strong vibration also of the carotid arteries comes on frequently in the advance of the fever, though the pulse at the wrist may be small, nay, even low: This is a certain sign of an impending delirium.

The profusion of spirits, weakness, and faintness, are often surprisingly great and sudden; sometimes, when the pulse seems tolerably strong, the respiration is very laborious, and interrupted with a kind of sighing or sobbing, and the breath is hot and offensive.

There is generally a sort of lumbago, or pain in the back and loins, a weariness, soreness, and pain in the limbs. Sometimes a great heat, load, and pain at the pit of the stomach, with a perpetual vomiting of porraceous or black bile, of a nauseous smell, with a troublesome hiccup.

The tongue at the beginning is white, but grows daily more dark and dry, or of a shining, livid colour, with a kind of bubble at the top; sometimes exceeding black for many days: At the height, it is generally dry, stiff, and black, and the speech scarcely intelligible.

The thirst, in the increase of the fever, is commonly very great, sometimes unquenchable; and all the drinks seem bitter and naukish; at other times there is no thirst,

though the mouth and tongue are exceedingly foul and dry; this is a dangerous symptom, and ends in a phrenzy or coma. The lips and teeth, near the state, are furred with a very black tenacious furde.

At the onset of the fever, the urine is often crude, pale, and rapid; but grows to so high a colour as to resemble a strong lixivium, or citron urine, tinged with a very small quantity of blood: it has no sediment, or cloud, for many days together; but by degrees grows darker, like dead strong beer, and smells offensive.

The stools, especially near the state, or in the decline of the fever, are for the most part very offensive, green, livid, or black, frequently with severe gripes or blood. When they are more yellow or brown, the less is the danger: but the danger is greatest of all when they come away insensibly. If the belly be hard, swelled, and tense, it is a very bad symptom. A gentle diarrhoea is often very beneficial, by which nature carries off the morbid matter.

The more florid the spots are, the less is the danger; and it is a good sign, if the black or violet become of a brighter colour. The large, black, or livid spots, are almost always attended with profuse bleedings. The small dusky, brown spots, like freckles, are almost as bad as the livid and black. Sometimes they are attended with profuse, cold, clammy sweats; at which time the spots vanish without any advantage.

The eruption of the spots is uncertain; sometimes they appear on the fourth or fifth day; sometimes not till the eleventh, or later. The *vibices*, or large livid or dark greenish marks, seldom appear till very near the fatal period. Sometimes about the eleventh or fourteenth day, when the sweats are profuse, the spots disappear, and vast quantities of small, white, miliary pustles break out. If there is an itching, smarting, red rash, it commonly greatly relieves the sick, as well as large, fretting, watery bladders on the back, breast, and shoulders. A scabby eruption about the lips and nose is a salutary symptom; the more hot and angry the better. Brown dark aphthae are more uncertain and dangerous, as well as those exceeding white and thick like lard. They are followed with difficulty of swallowing, pain and ulceration of the fauces and oesophagus, with incessant hiccup; the whole *primæ viæ* are at length affected, a bloody dysentery comes on, and a mortification of the intestines.

Pringle observes, that in hospital, goal, or camp fevers, the first complaints are gentle horrors, and little feverish heats, alternately succeeding each other, with loss of appetite; the disorder being greatest at night, the body is hot, the sleep interrupted and not refreshing. They have constantly some pain and confusion in the head, chiefly about their forehead; the pulse is at first but little quicker than the natural, and the drought, if any, is inconsiderable. They are too ill to mind business, and too well to be confined. In this state, a change of air, with a vomit and sweat, will perform a cure; yet a large bleeding at this time will sink the pulse, and bring on a delirium.

When the symptoms come on quick and violent, the fever seems to be inflammatory, and can only be distinguished by a knowledge of the circumstances; and bleeding yields

no relief, but exasperates the complaints. The aforesaid symptoms are now more high, with great lassitude, nausea, and pains in the back, with pain and confusion in the head, and great dejection of spirits.

The pulse at this time is generally quick and full: now a moderate bleeding affects the pulse but little; if large, it will sink, and bring on a delirium. The worst kind of blood is when the crassamentum is dissolved, which is a sign of high putrefaction.

If the patients lie warm, the body is generally costive; if cold, there is a diarrhoea. If they have bilious stools when they are warm, they are critical, and not to be checked unless immoderate. In the worst kind of these fevers, in the last stage, a diarrhoea commonly carries the patient off; but then the stools are involuntary, colliquative, ichorous, or blackish, and of a cadaverous smell, which are the effects of a mortification in the bowels.

The heat of the body at first is not considerable: but if the pulse is felt for a while, there is an uncommon heat, which remains upon the fingers some minutes afterwards. A day or two before death, the extremities feel quite cold, and then the pulse is hardly to be distinguished.

The skin is generally dry and parched; yet in the beginning there are often imperfect sweats, without any relief. A continued and generous sweat is the surest cure.

The tongue is generally dry, hard and black, with deep chaps; but towards the last it is soft and moist, and the colour is a mixture of green and yellow. The drought is sometimes great, at other times very little.

Some preserve their senses through the course of the disease, except a confusion and stupor; but few keep them till death, if it prove fatal. They sleep seldom, and seem to be pensive and in deep thought. The face is not ghastly nor morbid, till towards the last. The confusion of the head often rises to a delirium, especially at night, but seldom changes to rage. A tremor is more common than a subultus tendinum. The pulse sinks all along, the stupor or delirium and tremor increase, and the spirits are relieved in proportion to its rising to the head. Frequently the patient is dull of hearing from the very beginning, and at last grows almost deaf.

When the delirium is at its height, the face is commonly flushed, and the eyes red, unless after large evacuations; then it appears meagre; the eyelids in slumbers are only half shut; and the voice, which is constantly slow and low, sinks to a degree scarce to be heard.

When the fever is protracted with a low pulse, they have a particular craving for something cordial; and nothing is so acceptable as wine. They long for no food; but will take panada, if mixed with wine.

There are spots, but not always. In hospitals they are less usual at the first breaking out of the disease; but when the air is more corrupted, the spots are common. They are of the petechial kind, of an obscure red, paler than the measles, not raised above the skin, of no regular shape, but confluent. These spots are very irregular, sometimes appearing on the fourth or fifth day, and at others on the fourteenth. They are neither critical nor mortal signs, but dangerous; if purple, they are more ominous, but not absolutely mortal. In a few cases there have been purple streaks and blotches. These sometimes,

as well as the spots, do not appear till after death. This fever, on account of its exacerbations at night, may be looked upon as the lowest degree of the remitting kind.

The duration is uncertain, and in proportion to the virulence. Their course is generally from fourteen to twenty days: some have died or recovered after four weeks. When the course is long, it commonly terminates in abscesses of the parotid or axillary glands, sometimes in an hectic: Some, after this fever is over, fall into an irregular intermittent; many complain of a pain in their limbs, and want of rest; and almost all of great weakness, confusion in their heads, and noise in their ears. When the air is highly malignant, the disease terminates, in five or six days, either in death or a critical sweat.

The most peculiar symptoms of this disease, are always a singular attack upon the head, as a stupor, or pain; and if it lingers, a slow low voice, and sinking of the spirits, without any large evacuation; pale urine, petechial spots, the bad effects of large bleeding, or too many clysters; lastly, the disengagement of cooling medicines, excepting in the beginning; and on the other hand, the agreement with wine, volatiles, and other cordials, during the greatest part of the disease.

As to the prognostics, the spots are so far from being salutary, that the more plentiful they are the greater is the degree of the corruption: when they are livid, lead-coloured, and of a greenish black, they shew a sphacelous corruption. Those who escape are not freed by a cutaneous excretion, but by large sweats, breathing a stinking acor; or by critical fluxes of the belly; which happen by the benefit of nature, when the corruption of the fluids is not great. Many are apt to fall into a sphacelous corruption of the stomach, intestines, and other viscera, or into a phreny, or more frequently into an anginous inflammation of the fauces and oesophagus, as appears from the intolerable smell which happens after death. This unhappy event is prefaged, if there is no thirst, or one that is unquenchable; if the tongue is dry, chapt, black; the fauces inflamed and beset with fordes, with difficult swallowing; if, after the eruption of the spots, a difficult breathing and straitsness of the breast remains and gains ground; or if a delirium increases after sweating, and a flux of the belly, the urine being at the same time turbid, and depositing no sediments; lastly, if the eyes are dim, the patient catching at straws; if there is a subultus tendinum, if the excrements come away insensibly, or if there is a cold sweat with convulsions,

Pringle observes, that those who are weakened by other distempers, or their cures, are more susceptible of the goal or hospital fevers than the strong and vigorous; and that one who is recovered is more subject to relapse, than he who is to be first attacked.

All the prognostics, says he, taken singly, are uncertain. The following signs are good: to have no delirium; to have the pulse neither very low nor quick, or, if sunk, to have it rise by wine or cordials, with an abatement of the delirium; and to have the tongue moist, and of a natural colour. It seems peculiar to this fever, that deafness is generally a good sign. The natural and best crisis is by sweat, when the pulse rises, and the symptoms

toms abate; next to that is an insensible perspiration, which is known by the softness of the skin, moisture of the tongue, and a remission of the other symptoms. Bilious stools, with turbid urine, and a moist tongue, may be considered as signs of a favourable crisis. But the contrary of all these are bad; as also the subfultus tendinum, inflamed eyes, and great anxiety. It is observed to be among the worst signs, when the patient complains of blindness, or when he cannot lie but on his back, and pulls up his knees; or if, when insensible, he endeavours to uncover his breast, or makes frequent attempts to get out of bed. If there are ichorous, cadaverous, and involuntary stools, it is a sign of certain death.

The formal ratio of these pernicious fevers, consists in the putrid dissolution or coagulation of the blood and vital fluids, especially of that highly elastic fine fluid which is contained in the blood, and separated in the brain and spinal marrow, by which it is distributed by the nerves to all the body, induced with sense and motion, for it greatly vitiates and defiles this liquid. However, such is the nature and power of that poisonous vapour, by which sound bodies are infected, that it not only induces a putrid fermentation into the blood and other fluids, but acts immediately on the inward and nervous parts of the brain, which it corrupts, and produces a languor in the vital and animal powers, even while the state of the blood and humours remain free from corruption.

This, virulent vapour enters the body by the nostrils, fauces, and bronchia; whence it immediately reaches the nerves in the brain, and renders the patient light-headed, with a dulness of the head, and a loss of strength, and a vertiginous affection. It likewise mixes with the saliva, descends into the stomach, which is a nervous part, and there takes up its principal residence: whence the bad symptoms generally appear first in the stomach and præcordia, with a nausea and an inclination to vomit, as also a diarrhœa with gripes, or a coliciveness, with loathing of food, anxiety of the præcordia, and watery eructations from the stomach.

Hence the reason evidently appears, why nothing is more proper to guard against this disease than turning away one's face from the patient, frequent spitting, chewing angelica, zedoary, or pimpernel, and smoking tobacco: hence likewise appears, why the force of this poison is exerted in the stomach, which is beset with copious crudities, and pituitous and salivary fordes; and likewise why gentle emetics, joined to alexipharmics, commonly destroy the disease in the bud.

It may be induced by a bad state of the air: for a long moist, rainy, cloudy, and southerly state of the air, dulls and depresses the motions of the solids and fluids necessary for life: to this may be added a long and frequent inundation of water, which is apt to generate putrid diseases; as likewise the exhalations arising from putrid unburied bodies, or from the excrements of animals, especially if confined and shut up from the air.

In the regimen, it is necessary, if possible, to breathe a serene, temperately warm air. The room should not be heated too much, it being found to be hurtful. The patient should eat nothing solid in the decline of the disease, nor after it. A free use of food, of nourishing

and comforting broths abounding with oleous particles is pernicious, especially about the critical days, in the state of the disease, or where there is any critical evacuation. Nothing is more hurtful than an erect situation.

Alexipharmics, volatile salts, hot and spiritous bezoards, are hurtful, especially with a hot regimen: for they dissolve the blood, and increase the number of spots; or cause head-achs, inflammations, or copious sweats.

Bleeding has been good in plethoric bodies, and in those who have been accustomed to hæmorrhages; on the contrary, if the patient is low or weak, bleeding is hurtful.

Gentle vomits are useful by way of prevention, and in the very beginning of the disease; but in the progress and state have had a bad effect.

Blisters have been greatly praised in the state of the disease, when there has been a delirium, a sopor and convulsions, being applied to the neck.

We reject all opiates and soporiferous medicines, on account of the pulle and want of strength; because they retard the excretions, increase the malignity, and so hasten death.

The medicines used are elder-flower water, that of limes, elms, roses, of the tops of scordium, scabious, and carduus benedictus; as also syrups of citrons, pomegranates, and the juice of roses; powders of mother of pearl, diaphoretic antimony, crabs-eyes, amber, terra sigillata, burnt hartshorn, pure nitre. Alexipharmics are, camphire, essence and extract of scordium, vincetoxicum, the bezoardic spirit and tincture, the essence or spirit of vitriol, and dulcified spirit of nitre: Moisteners, the decoction of scorzonera, shavings and jelly of hartshorn; Analeptics, orange-flower water, fresh oil of citrons, with sugar, confectio of alkermes, and balsam of life: Antispasmodics, essence of castor, cinabbar, and succinated spirit of hartshorn.

In the beginning of the disease, use a bezoardic powder of nitre, and a little camphire, often repeated; in the progress and state of it, a mixture of temperate waters, diaphoretics, analeptics, antispasmodics, and cordial bezoardic powders, with a little juice of citrons. In the drink put nitre, or philosophic spirit of vitriol, or sulphurated cyllus of antimony, to keep the body open. Also give drink of the filtrated decoction of hartshorn, and root of scorzonera, either hot or cold. About the critical day give gentle alexipharmics, with things to promote sweat when nature seems to tend that way.

This is the best and surest method of cure. But if the vomiting is too great, with an anxiety of the præcordia, and profuse diarrhœas, accompanied with gripes, apply outwardly Venice treacle, expressed oil of nutmegs, camphire, oil of cloves, and balsam of Peru, mixt together, to the region of the stomach. If a diarrhœa exhausts the patient too much, give a nitrous bezoardic powder, with a little camphire, and theriaca cœlestis. If the body is colive, with gripes, prescribe lenient clysters, or such as are made entirely of oil. To raise the strength, allow spiritous things, such as comfort and are aromatic; but they must be externally applied to the pulses or pit of the stomach, or nostrils. To quench thirst, give an electuary of Muscovada sugar and dulcified spirit of nitre.

Nature

Nature many times strives in vain to discharge the irritating matter, by vomit, without the assistance of art; and therefore something to promote it will render it much easier; which may be done by an infusion or decoction of ipecacuanha, or oxymel scilliticum, with a slight infusion of camomile flowers..

The primæ viæ should be unloaded by very gentle methods, such as clysters of milk, sugar and salt; laxatives of manna, cream of tartar; Glauber's purging salt, tamarinds, and rhubarb.

When there are signs of redundancy of the bile, it should be forthwith discharged by vomit or stool, as nature points out; which is often succeeded by an amazing change for the better, where an inexpressible anxiety, load on the præcordia, perpetual sickness, eructation, and singultus, had preceded.

Between the seventh and fourteenth day, nature endeavours to relieve herself by vomit, or more frequently by loose stools; then given a gentle laxative the eighth and ninth day, unless some eruption appear, or a kindly sweat forbid it.

But the constant and grand effort of nature, is to throw off the putrid malignancy through the pores of the skin. If it be a breathing sweat at the state of the disease, and the pulse grows more open, soft, and calm, a little before and during its continuance, it is always salutary; but if it be profuse, cold, clammy, or partial, about the head and breast only, the sign is not good. Profuse sweats in the beginning are generally pernicious, especially if a *rigor* supervenes.

Sweats should never be forced by violent hot medicines, regimen, &c. Plentiful sudorific diluents will be sufficient, and gentle cordial diaphoretics.

As acids and subastringents are given to preserve the crasis of the blood and tone of the vessels, and to prevent the farther putrefaction of the humours, diaphoretics, especially camphire, should be joined with them.

Dr Brookes used the following prescription of the bark for many years with success, not only in intermittent and slow nervous fevers, but also in the putrid, pestilential and petechial, in the decline, though the remissions have been very obscure; but if the patient is costive, or hath a tense or tumid abdomen, he prescribes a dose of rhubarb, manna, or the like.

Take two ounces of Peruvian bark in powder, an ounce and a half of orange-skin, 3 drams of Virginian snake root, 4 scruples of English saffron, 2 scruples of cochineal, and 20 ounces of spirit of wine. Mix and infuse the ingredients in a close vessel for three or four days, and then filtrate the infusion.

Of this give from a dram to half an ounce every fourth, sixth, or eighth hour, with ten, fifteen, or twenty drops of elixir of vitriol, out of any appropriated draught, or diluted wine. The above composition tends to strengthen the solids, to prevent the farther dissolution and corruption of the blood, and in the event to restore its crasis.

With this view also give a generous red wine, as a most noble, natural, subastringent cordial, which is of high service in the state, but more especially in the de-

cline of these fevers, acidulated with the juice of Seville oranges or lemons, as also with cinnamon, the rind of Seville oranges, and the like, to which a few drops of elixir of vitriol may be added. Rhenish and French white wines, when diluted, are also a most salutary drink, and generous cyder is little inferior to either.

Of the PESTILENTIAL FEVER.

A pestilential fever is a most acute one, arising from a poisonous miasma, brought from eastern countries; and unless it is immediately expelled out of the body, by the strength of the vital motions, by buboes and carbuncles, it is fatal.

It differs from other contagious, malignant, and eruptive fevers, because it is the most acute; for it sometimes kills on the first, and sometimes on the second day. Besides, in our climate it is not epidemic or sporadic, from a bad way of living, or unhealthful air; but happens when it is most salutary, from contagion alone. There is something very singular in this infectious miasma; for though it is apt to spread at a strange rate, yet it will abate by intense cold, and be plainly extinguished: wherefore in a cold season, and very cold countries, it either does not appear at all, or in a very mild degree; whereas if the climate is hot, it is not only most vehement, but most common.

In this, as in all other contagious diseases, the venous miasma is swallowed with the air, and insinuates itself in the salivary juice, where its tragedy is first acted. Whence it assaults the head, brain, nerves, and animal spirits, producing a torpor in the head, a heaviness, a sleepiness, a violent pain, a stupor of the senses, a forgetfulness, inquietude, watching, and loss of strength. From the fauces it proceeds to the stomach, creating loathing of food, nausea, anxiety of the præcordia, a cardialgia, attended with fainting, reaching to vomit, and vomiting itself. Hence it proceeds to the membranes of the spinal marrow, and the coats of the arteries, producing horrors, a languid, small, contracted, quick pulse, and even fainting. All these are generally signs and symptoms of the plague; which are of a more violent and quick operation, in proportion to the virulence of the pestilential miasma.

All plagues are not of the same nature, but vary according to different constitutions and circumstances. Those who have written of the plague universally agree, that spongy and porous bodies of an obese habit, of sanguine and phlegmatico-sanguine constitutions; women, young persons, and children; persons of a timid disposition, that are poor, live hard, or are given to luxury, and sit up late at nights: are more apt to be afflicted with this disease, than the strong and intrepid, lean, nervous; those induced with large vessels; men, or old persons obnoxious to the hæmorrhoidal flux, and who have issues and open ulcers. Nothing brings on this distemper more than fear, dread of death, and a consternation of the mind.

Pestilential fevers are so called, when the patient falls into sudden weakness: for it is a kind of malignant fever, attended with more grievous symptoms; the patients die in a short time, that is, in two, three, or four days, and sometimes sooner. If malignant fevers arise in war-time
among;

among the soldiers, they are called camp-fevers; in Hungary, an Hungaric fever. But the plague, or pestilence, is known when buboes and carbuncles arise in various parts of the body. The sweating sickness had its rise in England, in which the patient fell into a violent sweat, of which many died in a day's time.

The pestilential poison disturbs all the functions of the body; for unless it be expelled to the external parts, it is certainly fatal. Nor is this to be done as in other fevers, by large sweats, by stools, by a flux of urine, by customary evacuations of blood, or by bleeding at the nose, either natural or artificial, for they rather hasten destruction. The salutary and critical excretion which perfectly solves the pestilential disease, is by tumours in the surface of the body not otherwise than the erysipelas, between the third and fourth day; and the sooner the better, for then the symptoms are mitigated. The pestilential tumours are of two kinds; the first arises in glandulous places, most commonly in the groin and arm-pits, sometimes in the parotid and mammary glands, as also the lower maxillary, under the chin, and in those near the aspera arteria. It is a hard, painful, tense swelling of the glands, with great heat; and if they are salutary, being swolen, they grow soft, and suppurate. The other sort is the anthrax or carbuncle. Celsus describes it in this manner. It is a swelling on which there are pustules, which rise but little; they are black, sometimes sublivid or pale. In this there seems to be a fæces; it is black underneath. The body itself is more dry and harder than usual. There is as it were a crust about it, surrounded with an inflammation; nor can the skin be raised up in the part, but is joined to the flesh underneath. Mindererus, who was present at the plague, says, that a carbuncle is of the size of a grain of mustard-seed; and about its edge, there is a circle, or burning halo, of a large size. The flesh which it seizes is like an eschar or putrid flesh, and falls off as if torn out by a wolf. No part of the body is free from these carbuncles; but they generally lay hold of the membranes of the muscles, and the nervous and fibrous substance of the skin, especially in the back, arms, and thighs. At first there is an exquisite itching in the part; which when scratched, pustules arise; they are of a red, livid, or whitish purple colour, or sometimes black. When the pustules are pressed, they seem to be full of pus; under which there is an ash-coloured crust, which being taken away, the flesh appears corrupted and spongy, with intolerable pain and burning of the circumjacent flesh, which is followed by a mortification of the part.

When the plague is fatal, some die of a fainting the first or second day. But in many, when the poison is not expelled, or, if expelled, returns back, it brings on a mortification of the nervous coats of the noble parts, of the pleura, oesophagus, stomach and intestines, or the meninges of the brain; which creeps speedily to all the viscera, and the blood itself; whence the carcases swell, and have a most intolerable stench. Sometimes, when the pestilential tumours are too plentiful, they die of a symptomatic fever, from the inflammation, pain, and intolerable heat.

It has been before remarked, that the plague is not a native of our country, but is brought from remote pla-

ces: whence the best preservative is to fly to a distant country; for the same reason, those princes best consult the welfare of their subjects, who in the time of the plague endeavour to prevent the spreading of the infection, and, when a family is afflicted, separate the well from the sick, and burn all their moveables. While this disease reigns, all persons should live temperately, avoid an excess in the use of the non-naturals, and abstain particularly from violent affections of the mind, and every thing else that debects the strength, disturbs perspiration, and generates crudities in the primæ viæ; the mind is especially to be supported, and fear, dread, and pusillanimity are to be banished; for more die of terror than of the plague itself.

As in the small-pox, the management consists in clearing the *primæ viæ* in the beginning, in regulating the fever, and in promoting the natural discharges; so in the plague, the same indications will take place. In the plague, indeed, the fever is often much more acute; the stomach and bowels are sometimes inflamed, and the eruptions require external applications, which to the pustules of the small pox are not necessary.

When the fever is very acute, a cool regimen is necessary; but when the pulse is languid, and the heat not excessive, moderate cordials must be used. The most gentle emetics may be given; the best is ipecacuanha, if the stomach or bowels are not inflamed, for then certain death must be expected.

As for the eruptions, they must be brought to a suppuration as soon as possible; and as soon as they appear, fix a cupping-glass thereon, without scarification; and when that is removed, apply a suppurating cataplasm, or plaster of warm gums.

If the tumors will not suppurate, as the carbuncle seldom or never does; yet if a thin ichor or matter exudes through the pores, or if the tumors feel soft to the touch, or, lastly, if it has a black crust upon it, then it must be opened by incision, either according to the length of the tumor, or by a crucial section. If there is any part mortified, as is usual in the carbuncle, it must be scarified. Then it will be necessary to stop the bleeding, and dry up the moisture with an actual cautery, dressing the wound afterwards with dressings and pledgets, spread with a common digestive.

The next day the wound ought to be well bathed with a fomentation of warm aromatic plants, with spirit of wine in, in order, if possible, to make it digest, by which the sloughs will separate. After this, the ulcer may be treated as one from a common abscess.

But the patient runs great hazard in this way, notwithstanding the utmost care; therefore artificial discharges for the corrupt humours should be attempted. To this purpose, large bleeding and profuse sweating are recommended to us upon some experience.

As for sweating, as Sydenham advises, it must be continued without intermission.

If there is a vomiting, the patient should be made to sweat with the weight of the bedcloaths alone, drawing the sheet up to his face.

When the sweat is begun, it should be promoted with sage posset-drink, or small-beer, in which mace has been boiled,

boiled, repeating them pretty often for twenty-four hours; in the mean while, the spirits of the patient are to be kept up with comforting broths. The by-standers should forbear to wipe off the sweat, nor should the patient change his linen all that time, which is a necessary caution; if it be stopped before that time, it will be to no manner of purpose; during the sweat, the diarrhoea, if any, and the vomiting, will stop of their own accord.

Theriac, and the like solid medicines, being offensive to the stomach, are not the most proper sudorifics. An infusion of Virginia snake-root, in boiling water, or, for want of this, of some other warm aromatic, with the addition of about a fourth part of aqua theriacalis, is safer.

Those who are obliged to be near the sick, must take care that the miasmata do not approach their vital juices, nor yet the salival. To this purpose, frequent spitting, and washing the mouth with vinegar, or wine, or snuffing them up the nose, are useful. The efficacy will be still greater, if they are imbued with rue or citron rind. For an acid is the genuine antidote of a putrid and sulphureous miasma. Wherefore it is much safer to hold acids in the mouth, than alexipharmic roots. It will be likewise proper to get a few spoonfuls of Rhenish wine, or bezoardic vinegar, diluted with water or wine, and so take them. The Turks deal much in the juice of lemons.

When the plague is actually begun, and the body is collicive, a gentle clyster should be used. Then a sweat should be promoted (twenty-four hours at least,) that the poison may exhale and pass through the skin; and episthems to the heart will not be without benefit, though they reach only to the right orifice of the stomach, and its nervous coats; they may be made of *theriac*, expressed oil of nutmegs, camphire, saffron, castor, and balsam of Peru. But above all, acids are highly praised; such as, juice of citrons, Seville oranges, lemons, vinegar, &c. which resist poison, putrefaction, and prevent the dissolution of the blood.

When the strength of the disease is vanquished, gentle laxatives will be proper to expel the forces during the course of this disease.

It is worthy observation, that few medicines are best; for which reason people of the lower class generally come off better than persons of distinction; and there is nothing worse than to give alexipharmics abounding with a hot volatile oil; much less ought volatile spirits to be given, for they fix the poison upon the nervous parts. Yet herbs and roots of this kind are not altogether to be condemned, if mixed with acids and nitre. A mixture of *carduus benedictus* water, and wine vinegar, when given to four spoonfuls, with a dram of crabs-eyes and theriaca, and repeated, were very useful in the plague at Hall in 1682. In the plague likewise in Lombardy, 1526, many recovered with the juice of goats rue, vinegar, water of *carduus benedictus*, and a little *theriac*, given to make the patient sweat: and Thoner observes, that nothing was of any advantage in the plague except theriacal vinegar given in the beginning to promote a sweat. And in the year 1544, when a malignant fever raged among the soldiers, a whole regiment was saved, to whom this vinegar was given in due time, except a very few. And in

the plague at Rome, vinegar with rue, pimpernal root, betony, garlick, and juniper-berries, with a little camphire added to the infusion, caused many to escape. Likewise the preservative water of Sylvius has been greatly esteemed, because of the vinegar. And Mindererus asserts, that unless alexiterials be given within twenty-four hours, all medicines are vain.

Of the MILIARY FEVER.

A miliary fever is not unlike a catarrhal, and is attended with a more intense motion of the vascular and nervous system, whereby a corrupt lymphatic matter of a peculiar nature is expelled from the inward, and more especially the nervous parts, to the surface of the skin, in the form of small, rough, miliary pustules, sometimes red, and sometimes white.

These small pustules are exceeding numerous, causing a corrugation, roughness, and dryness of the skin, and have a fetid smell peculiar to themselves. There is no eruption so instant as this, for it will sometimes strike in suddenly, and as suddenly appear again, and is attended with an itching pricking sensation more than any other kind. Other eruptions are common to all countries, and are equally vexatious to men as well as women; but the miliary seems familiar and endemic to some places only, and more frequently attacks the female sex, especially in child bed. It is neither epidemic nor contagious; and seems rather owing to a fault in the viscera and fluids, than the temperature of the air.

The miliary eruptions are either red or white, and are both more or less acute, benign or malignant. The red are less dangerous, are generally free from a fever, and then are chronic, appearing at stated seasons of the year; but sometimes they are accompanied with an acute fever. The white seldom or never appear without a fever, and therefore are more dangerous. In these the lymph is affected with a kind of acidity; for the patient discharges plenty of serum by sweat, urine, stool or salivation, which are the effects of an acid which coagulates the thicker part of the blood, and separates the serum from it. Besides, all kinds of acids and refrigerants, not excepting nitre, freely taken, are most hurtful in this disease. On the contrary, absorbents and anti-acids, and things which render the blood spiritous, are most salutary. Women who eat much fruit, and such like trash, of the acceftent kind, and live idle sedentary lives, are most subject to this disease.

Sometimes the miliary eruptions are idiopathic, and sometimes symptomatic, and supervene to other fevers, especially the continual, when on the decline. They likewise appear very commonly with the measles, small-pox, putrid and spotted fevers, when drawing towards an end; and then they raise a new fever, whose attack the debilitated patient is not able to stand.

The idiopathic begins with a slight shivering, succeeded with heat and loss of strength, sometimes even to fainting. There is a straininess about the breast, attended with anxiety and deep sighs, restlessness and watching. There is a pricking kind of a heat perceived in the back, with an alternate succession of cold, shivering, and heat under the skin, but most sensible in the palms of the hands.

hands. Women in child-bed have the flux of the lochia stopped, and the milk recedes from their breasts. To these succeeds a roughness of the skin like that of a goose; and a great number of pustules appear, sometimes white and sometimes red, or both together, of the size of millet (or mustard) seed. They first beset the neck, then the breast and back, and afterwards the arms and hands. When these begin to rise on the surface of the skin, the more grievous symptoms cease. The pulse, which before was hard, contracted and quick, grows more soft, free, and slow; the dejection of mind goes off, the skin becomes moist, and the belly, which was bound so much that the patient could not break wind, now spontaneously admits him to go to stool. Afterwards the pustules ripen, and are full of a stinking ichor. The urine appears more saturated, and a singular fetid sweat, proper to this disease, breaks forth; the flux of the lochia in females returns, and within the space of seven or eight days the pustules disappear, with great itching in the extreme parts, drying up and falling off in scales. Then the patient recovers strength, and regains health.

It is hard to determine the day of the eruption of the pustules; but it is generally the tenth or eleventh day from the beginning, if the fever makes a regular progress; sometimes on the eighteenth, and sometimes on the twenty-first, or twenty-second day.

Bad signs are, when the miliary pustules appear and vanish by turns, and the symptoms continue violent; but it is worse if they quite disappear: Hence an oppression of the breast, with sighs, a straitness of the fauces, loss of strength, and great anxiety.

Fatal signs are, when the morbid matter not being thrown out again, there is an inward heat, and the extreme parts are affected with cold and shivering, and there is a cold profuse sweat; or, on the contrary, when the extreme parts are hot, and a notable sense of coldness is perceived in the abdomen, then the patient dies in a fainting fit, arising from a mortification of the stomach, intestines, brain, or womb.

The cure of this fever depends on the following things.

1. To correct and temperate the acrid morbid matter which disturbs the nervous parts. 2. To relax the spastic strictures of the nervous fibres proceeding from thence. 3. To evacuate the prepared morbid matter through the pores of the skin, and prevent its striking in.

To dilute the sharpness of the humours, and to appease the irritation of the nervous parts, the following decoction may serve for common drink.

Take shavings of hartshorn, scorzonera root, and saffaparilla, of each two ounces; and boil them in 6 pounds of water.

Let the patient be always kept in an equal moderate heat, and abstain from strong alexipharmics, and things actually hot, because they throw him into too profuse a sweat. But when there is an apprehension of the pustules striking in, then the decoction may be drunk hot, with moderate expellents, as the exigence requires. Nor should the medicines be too cooling, because they increase the anxiety and faintness. In the red sort, when there is an internal heat, with thirst and a great pulse, diaphoretics with a little nitre will be proper; even though red

and white pustules appear together. But nitre alone should be used with caution, especially when there are signs of malignity. No malt liquor should be drank, but the former decoction.

The belly should be neither too much bound nor too open; yet even the gentle laxatives are not to be given till the pustules begin to dry; and then there is nothing else required but an emollient clyster.

Bleeding should be cautiously used; for when the weakness is excessive, the sweats profuse, and the pulse quick, it must be omitted. On the contrary, it is necessary for childbed women, when the lochia are suppressed, and the symptoms of a miliary fever begin to appear; but then it must be done speedily, and the great anxiety, fainting, and difficulty of breathing will cease, and the pustules break out.

Blisters on the back are very proper for this disease; for they help to draw off the impure serous humours, and stimulate the fatigued nervous fibres to a contraction, so as to expel the morbid matter.

Of the SCARLET FEVER.

The scarlet fever may happen at any season of the year, but it appears most commonly towards autumn. It reigns chiefly among children. It begins with coldness and shivering, as in other fevers, without any violent sickness. Afterwards the skin is covered with red spots, which are larger, more florid, and not so uniform as the measles. The redness remains two or three days, and then disappears; then the cuticle falls off, and leaves behind it a sort of mealy scales, scattered over the body, which appear and disappear two or three times.

Let the patient abstain from flesh, all hot cordials, and spiritous liquors; let him not go out of doors, nor be confined constantly to his bed; and then medicines will be of little use.

Apply a blistering plaister to the neck, and every night give a paretic of diacodium; and after the fever ceases, let the patient be purged with a very gentle cathartic, agreeable to the age and constitution.

Of the MEASLES.

The measles are an eruptive catarrhal fever, generally epidemic, which by the increased vital motion of the heart and arteries throws on the skin an acrid, caustic, inflammatory matter, in the form of red spots. They begin with chilliness and shivering, and heat and cold succeeded by turns. The next day the fever comes on with great sickness, thirst, and loss of appetite; the tongue is white, but not dry. There is a little cough, a heaviness of the head and eyes, and a continual sleepiness. There is a sneezing and a swelling of the eye-lids, a serous humour oft distils from the nose and eyes, which are certain signs the eruption is at hand. In the face the spots are small; but on the breast broad and red, not rising above the surface of the skin. The patient often has a looseness, with greenish stools.

These symptoms continue and increase till the fourth, sometimes the fifth day; at which time spots like fleabites appear, increasing in number and magnitude, and in some places run together, rendering the face variously spotted.

spotted. These spots consist of very small red pimples, almost contiguous, and rising but little above the skin. They may be felt by a gentle touch of the finger, but the rising cannot easily be discerned by the naked eye.

From the face the spots gradually proceed to the breast, belly, thighs, and legs. The symptoms do not immediately vanish after the eruption, as in the small-pox, except the vomiting. The cough and fever increase, with difficulty of breathing. The weakness, and a delusion on the eyes, sleepiness, and want of appetite, still continue.

On the sixth day, and sometimes sooner, the skin of the face and forehead begins to grow rough; and the cuticle breaking, the pustules die away; while on the rest of the body the spots are broad and red. On the eighth day the spots disappear in the face, and are scarce perceivable elsewhere. On the ninth they quite vanish; fine, thin, light scales, like flour, falling off from the skin at that time.

The measles in general are not dangerous, unless from an insalubrious epidemical constitution of the year, which sometimes renders them malignant. This may be known by a sudden loss of strength, coldness of the extreme parts, great restlessness, vomiting, difficulty of swallowing, and a delirium. If petechial spots or military eruptions supervene, there is great danger. A continual cough, a looseness, and great inquietude, are bad. Profuse sweats are no good sign. When the disease is ended, if the cough and hoarseness remain, a consumption and hectic will follow, without speedy assistance.

Those who die of the measles are generally suffocated on the ninth day. Some, when the disease is ended, have a looseness, which continues several weeks, and brings on a mortal *tuber*: Some have a slow fever, with an atrophy and a swelling of the abdomen, which are fatal.

If children are suspected to abound with crudities in *primis viis*, it will be proper to evacuate with half a grain of tartar emetic, and syrup of succory with rhubarb. When there are worms, anthelmintics should be given. In adults abounding with blood, phlebotomy is necessary on the first days. Medicines too hot, and cold nitrous things, are equally hurtful. As soon as the eruption is ended a gentle cathartic is proper.

In a cough nothing is better than oil of almonds fresh drawn, mixt with syrup of capillaire; half a spoonful of which should be given often in water-gruel.

To absorbent and diaphoretic powders, half a grain of saffron may be added.

When this disease attacks women who are subject to hypochondriac or hysterical spasms, or when the menstrual flux is at hand, it is often attended with fainting fits, difficulty of breathing, with contractions of the throat, and great anxiety of the præcordia. Therefore the eruptions are not to be driven out with hot remedies, but rather with such things as allay spasms, paregoric and carminative clysters, sometimes bleeding, as also a little castor and nitre mixt with bezoardic powders. By these means the spots will appear in a short time.

When a diarrhoea happens, it must be cautiously treated, and not hastily stop; because it carries off a great deal of silt, and often puts an end to the disease. Then it

it will be best to wash the acrimony out of the intestines by demulcent clysters. But if, when the disease is over, the diarrhoea continues obstinate, it will be proper to add a few grains of the bark of eleutheria with bezoardic powders.

When there are hæmorrhages, which are generally signs of malignity, nothing must be used that is directly astringent, much less opiates and anodynes.

If the patient falls into too profuse a sweat, so that the linen is quite wet, it must be changed very cautiously for such as is well aired and warm, otherwise the spots will strike in. Many have been killed in a few hours, by a sudden change from hot to cold.

When the spots are gone, the patients should not expose themselves to the air; but be careful of their diet; otherwise they may fall into an asthma, suffocating catarrh, or consumption.

Sydenham, for the cough, orders the following.

Take an ounce and an half of the pectoral decoction; syrup of violets, and true maiden-hair, of each an ounce and a half: make them into an apozem, and take three or four ounces four times a-day.

Let the patient keep his bed for two days after the first eruption.

If, after the measles disappear, a difficulty of breathing, fever, and other symptoms, should supervene, resembling an inflammation of the lungs, let blood be taken away freely from the arm, once, twice, or three times, as occasion shall require; leaving a due space between each bleeding; and let the pectoral apozem above described be given, or oil of sweet almonds alone. About twelve days from the invasion, let the patient be purged.

Of the SMALL POX.

THE small-pox is commonly divided into two kinds; the distinct and confluent.

The distinct sort begins with chilliness and shivering, intense heat, a violent pain of the head and back, an inclination to vomit: in adults, a great propensity to sweat; a pain at the pit of the stomach, if it be pressed with the hand; a dulness and drowsiness, and sometimes epileptic fits, especially in children; and if the breeding of teeth is over, it is a sign the small-pox is at hand; for if the fit happens over night, the small pox will appear in the morning, and are, generally speaking, of the favourable sort.

On the fourth day from the beginning they break out, sometimes later, seldom before, at which time the symptoms either abate or wholly disappear.

The spots at first are reddish, and spread themselves over the face, neck, breast, and the whole body. Then there is a pain in the fauces, which increases as the pustules grow turgid.

On the eighth day the spaces between the pustules, which hitherto were white, begin to grow red and swell, and to be affected with a tenative pain. The eye lids are puffed up, and close the eyes; next to the face, the hands begin to swell, and the fingers are distended; the pustules of the face, before smooth and red, begin to be rough, (the first sign of maturation,) and whitish, and throw out a yellowish matter, in colour like a honey-comb.

The

The inflammation of the face and hands being now at the height, the interstices between the pustules are of the colour of damask roses; and the more mild the disease is, the greater is the likeness.

The pustules about the face, as they ripen, grow more rough and yellow. But on the hands and the other parts of the body, they grow whiter and less rough.

On the eleventh day the swelling of the face and inflammation disappear; and the pustules being ripe, and of the size of a large pea, grow dry, and fall off.

On the fourteenth or fifteenth day they vanish entirely; except some oblongate pustules on the hands, which continue a day or two longer, and then break. The rest come off in branny scales, and in the face leave pits behind them.

Through the whole course of this disease the patient's body is either wholly bound, or he goes to stool but very seldom. Generally those who die of the small-pox, die on the eighth day in the distinct, and on the eleventh in the confluent sort. Then the face, which ought to be turgid, and the interstices florid, on the contrary is flaccid and whitish, at the same time that the pustules are red and elevated, even after the death of the patient. The sweat, which was injudiciously promoted by cordials and a hot regimen, suddenly ceases; in the mean while the patient is seized with a phrensy, a violent anxiety, a tossing and sickness; he makes water often and little, and a few hours close the tragical scene.

In the confluent sort there are the same symptoms, but much more violent. The fever, anxiety, sickness, vomiting, &c. more cruelly torment the patient; yet he does not so soon fall into a sweat, as in the distinct kind. A looseness sometimes precedes the eruption, and continues a day or two after it.

On the third day, sometimes before, seldom later, the spots appear; and the sooner, the more will they run together. Sometimes the eruption is retarded till the fourth or fifth day, by some terrible symptom; such as, a most acute pain in the loins, like a fit of the gravel; in the side, like a pleurisy; in the joints, like the rheumatism; in the stomach, with a sickness and vomiting.

But the symptoms do not remit after the eruption, as in the distinct sort; but the fever and other complaints continue to molest the patient many days after. Sometimes the spots appear like an erysipelas, sometimes like the measles, but are distinguished from them by the time of the eruption. As the disease increases, they do not rise to any considerable height, being intangled with each other in the face; but appear like a red blifter, and cover all the countenance, which swells sooner than in the distinct kind. Afterwards they seem not unlike a white pellicle glued to the face, and are not much higher than its surface.

The eighth day being past, the white pellicle grows daily more rough, and of a dusky colour. The pain of the skin becomes more intense, and at last, in the more cruel kind of this disease, they do not fall off in broad large scales, till after the twentieth day. But this in the mean time is worthy of observation, that the more the ripening pustules are of a brownish colour, they are the worse, and the longer in falling off; and the more yellow

they are, the less they run together, and the sooner they disappear.

When the pellicle falls off, there is no roughness on the face, but branny scales soon appear in its room, of a very corrosive nature, which leave deep pits behind them, and sometimes ugly scars; sometimes the shoulders and back are quite deprived of their cuticle.

The danger of the disease is to be estimated from the number and multitude of the pustules on the face alone. The pustules of the hands and feet are the greatest; and the farther they are removed from the extremities, the less they are; in adults a salivation, and in children a diarrhoea, is a sign, though not always, of the confluent sort. The spitting sometimes begins with the eruption, sometimes two or three days after it; the matter is at first thin, but on the eleventh day it is viscid, and hawked up with difficulty; the patient is thirsty and hoarse, extremely sleepy, and his senses exceeding dull: he sometimes coughs when he is drinking, and the liquor regurgitates through his nostrils: then the salivation generally ceases, but the swelling of the face ought not to go down quite till a day or two after, when the spitting is over; if the hands do not begin to swell remarkably, and continue so for some time, the patient will suddenly leave the world.

The diarrhoea does not so soon attack children as the salivation does men. In both sorts of this disease the fever predominates from the first onset till the eruption; then it abates till the pustules are ripe, at which time it terminates.

The day on which the patient is most in danger, in the least crude and most common sort of the confluent, is the eleventh from the first attack of the disease; in the more crude, the fourteenth; and in the most crude, the seventeenth: sometimes, but very seldom, the patient does not die till the twenty-first. But in the space of time from the eleventh to the seventeenth, as the evening comes on, the patient is daily tormented with a fit of inquietude.

In the management of the patient in the distinct sort, regard should be had to the season of the year, and the strength of the patient. Let this be a general rule, to keep the patient in bed during the first days of the distemper, taking care to defend him from the inclemency of the winter by proper means; and to moderate the excessive heat in summer by cool air. For the patient ought not to be stifled by heat and cloaths, nor should the eruption and perspiration be checked by cold. However, great care ought to be taken in general to supply him with pure and cool air; because a hot air causes difficulty of breathing, checks the secretion of urine, and increases the number of pustules on the internal organs of the body.

With regard to DIET, it ought to be very slender, moistening, and cooling; such as oatmeal or barley-gruel; and in the beginning, the best regimen is that which keeps the body open, and promotes urine. This end is obtained by boiling preserved fruits with their food, such as figs, Damascene plums, and tamarinds; and by giving them subacid liquors for drink; as small-beer acidulated with orange or lemon juice; whey turned with apples, boiled

boiled in milk; emulsions made with barley-water and almonds; Moselle, or Rhenish wine plentifully diluted with water; or any other things of this kind.

In the cure, Sydenham directs bleeding on any of the three first days to nine or ten ounces; and then an ounce, or an ounce and a half of emetic wine. But some physicians will not allow a vomit by any means, unless there is a nausea, and the head is much affected. Yet Hoffman judges it to be proper on the first day of the invasion, and prescribes two grains of emetic tartar dissolved in cinnamon water, to adults.

In youths and adults, it is often necessary to take away blood two or three times, only with an intermission of two or three days between each time. Blood-letting is so far from being an obstacle to the eruption of the pustules, if the patient is not too weak, that it forwards it considerably.

After BLEEDING, a vomit should be given, if the stomach abounds with phlegm or bile, or be loaded with food unseasonably taken. Otherwise a purge may be prescribed before the eruption of the pustules: which may be the infusion of senna with manna, or manna alone, especially for children; for no disturbance is to be raised in the body.

To keep the inflammation of the blood within due bounds, and to assist the expulsion of the morbid matter through the skin,

Take half an ounce of bezoar in powder, 2 drams of purified nitre. Mix, and beat into a powder.

Half a dram of this may be taken by an adult three or four times in a day; diminishing the quantity for children in proportion to their age.

Sometimes equal parts of these ingredients may be prescribed; and if the effervescence of the fever runs very high, a proper quantity of the spirit of vitriol may be added to the patient's drink. But if there be any reachings to vomit, they will be removed by draughts containing half an ounce of the juice of lemons, with one scruple of the salt of wormwood.

When the eruption of the pustules is completed, which generally happens on the sixth day from the attack, let the patient take an ounce of diacodium every evening till the tenth day after the invasion. On that night, if the small-pox be of the confluent kind, the dose must be increased to an ounce and a half; and an ounce in the morning; and so an ounce and half every night till the patient is recovered.

Whatever are the sort, and at whatever time of the disease a palsy shall happen, it is to be cured by paretics, given one after another till the end is obtained, only waiting to see the effect of one dose before another is ordered.

In the mean time, if the patient is constipated, which is generally the case, and the fever continues, the body is to be opened with a clyster every second or third day.

If the method is proper in the distinct small-pox, it will be found more necessary in the confluent, which is attended with greater fear and danger.

In every sort of this disease it is proper to open the body on the decline, that is, on the ninth or tenth day from the eruption, because a putrid fever generally comes

on about that time, while the pustules are drying, or upon the subsidence of the swelling of the inflamed skin, where there is no suppuration, which fever cannot be taken off with equal safety by any other means; but gentle cathartics alone are to be employed in this case, such as were directed before the eruption of the pustules.

It will also be of use at this time to take away some blood, if the heat be too great, and the patient have strength to bear it.

This putrid fever is by Sydenham called the secondary fever, which comes on with heat, inquietude, tossing, &c. and, unless prevented, takes off the patient in two or three days. He mentions this fever as coming on the eleventh day, or later; but this is to be understood from the time of the invasion, whereas Mead reckons from the time of the eruption. Sydenham prescribes large bleeding, and a cathartic two days after, viz: one ounce of lenitive electuary dissolved in 4 ounces of simple alexeterial water, together with the free use of paretics.

If the spittle through heat is so tough that it cannot be hawked up, let a gargle be frequently injected into the throat with a syringe. It may be compounded of barley-water and honey of roses.

When the matter of salivation grows very viscid, and begins to clog the larynx and trachea, the best method is to boil marsh-mallows, myrrh, and honey, in a sufficient quantity of water and vinegar, and to transmit the steam of the decoction into the patient's mouth, thro' a glass or tin tube, of such a shape and length as is most commodious for a recumbent posture.

From the eighth day to the end of the disease, garlic may be applied to the soles of the feet; which must be renewed every day, especially when the brain is affected.

When the pustules are perfectly dry and withered, the face may be anointed with a liniment, made of equal parts of oil of sweet almonds and pomatum, for two days and no longer.

Twenty one days after the invasion, let a vein be opened in the arm, and the next day give a cathartic, which may be repeated every other day three times more.

This is necessary, because no species of fever requires the body to be thoroughly cleared of the remains of the disease more than this. After the cathartics, the body is to be restored to its former state by a course of milk, especially that of asses, with suitable food, and the air and amusements of the country.

As there are particular accidents in the small-pox which do not commonly occur, it will be proper to say something of them. Sometimes the patient is seized with convulsions just before the eruption, which is rather a good than a bad sign in children. In this case, blood-letting is carefully to be avoided; but a blister is to be applied to the neck, and to the soles of the feet. Plaisters made of equal parts of the cephalic and blistering plaisters; not forgetting to give antispasmodic medicines inwardly. The chief are wild Valerian-root, Russian castor, and the spirits of volatile salts chemically extracted from animals.

In adults, the thing is otherwise; for they, if not too weak, may lose a moderate quantity of blood, and then be put into the foregoing method.

Haller tells us, that camphire affixes greatly in filling the small-pox of the confluent kind with petechiæ; and Monro, that the Peruvian bark does the same, that it filled the empty vesicles with matter, changed the watery fanies into thick white pus, made the petechiæ or spots turn gradually to a pale colour, and caused the pox to blacken sooner than was expected. The dose in powder, is from ten to twenty grains, in some rich syrup, with an aromatic distilled water, every four or five hours. Children may take it in a clyster, with a small quantity of warm milk, after the bowels are unloaded with a preparatory clyster. If the clyster was retained too short a time, syrup of poppies was added, or disacordium. These injections were repeated morning or evening or oftner. The bark has had good effects in mitigating the secondary fever. When the lungs are greatly stuffed, it is not to be given.

When the eruption appears without much fear or pain, it is not without danger; for the pustules frequently do not tend to maturity, and there is no suppurative made. Hence the fever increases, with inquietude of body, anxiety of mind, difficulty of breathing, and a delirium, which carry off the patient in a few days. In this state, the fever ought rather to be raised than checked; and then warm medicines are to be directed which promote supuration, by increasing the motion of the blood, and thinning the humours, such as Virginia snake-root, contrayervarrow, saffron, assa fetida, myrrh, and the like.

But above all, **BLISTERS** must be laid on the limbs.

When the matter of the infection is over abundant, as it happens in bad cases, nature never fails endeavouring to throw off the load. Thus in adults a spitting comes on upon the first days of the eruption; whereas children have a looseness almost through the whole disease, which is not to be inconsiderately stopped. So in adults, if the spitting does not go on to our wishes, it ought to be promoted by medicines which stimulate the glands of the mouth, especially gargles made of a decoction of mustard-seed and pepper, with the addition of oxymel. For in the confluent and malignant small-pox, if this flux does not arise and continue to the end of the disease, it is a very bad sign.

The method of abating the rigour of this disease, and preventing the great mortality with which it was often attended, by inoculation, is now so well known and so generally practised, that a particular detail of it in this place is unnecessary.

Of the ERYSIPELAS, or St ANTHONY'S FIRE.

AN ERYSIPELAS is an eruptive fever, from which no part of the body is exempt; but it chiefly attacks the face. It begins with chills and shivering, and other common symptoms of a fever. The part affected swells a little, with great pain, and intense redness, and is beset with a vast number of little pustules; which when the inflammation is increased, are converted into small blisters.

This disease has great affinity with a pestilential fever; for it begins suddenly, with great shaking, heat, loss of strength, violent pain in the back and head; to which may be added vomiting, and a delirium; but this is to be understood of the worst sort. On the third or fourth day the malignant matter is thrown out on the surface of

the body, and then the symptoms a little abate. There is often a pain, redness, and tumour in the inguinal glands, from whence matter of a hot fiery quality descends to the feet. If the head is attacked, the parotid glands are affected; if the breasts, the axillary. The mammary and axillary glands are not seldom ulcerated, and affect the joints with a virulent corruption. And likewise, as in the plague, there is nothing more dangerous than the return of the expelled matter back from the surface of the body to the inward parts.

In some, especially young persons, the matter is not so virulent, nor the fever so great; the glands remain unaffected, and the eruption happens on the second day. This is not at all dangerous.

An erysipelas is either true, or simple and spurious, which is likewise called scorbutic. The simple only affects the surface of the skin, and readily yields to proper remedies. But the spurious is more chronic, is harder to cure, and often degenerates into malignant ulcers. Besides, this disease is sometimes idiopathic, or a primary disease; and sometimes symptomatic, or a secondary one. For instance, in the anasarca, the ascites, the yellow and black jaundice, a symptomatic erysipelas sometimes supervenes, and quickly kills the patient.

If it seizes the **FOOT**, the parts contiguous will shine; if it be attended with great pain, it will ascend to the legs, and will not bear to be touched.

If it attacks the **FACE**, it swells and looks red, and there are plenty of watery vesicles. The eyes are closed up with the swelling; there is a difficulty of breathing; the fauces and nostrils are very dry, often attended with a numbness and drowsiness: hence an inflammation of the brain is to be feared, or a mortal lethargy.

If it affects the **BREASTS**, they swell, and grow almost as hard as a stone, with exquisite pain, and they are very apt to suppurate. There is a most violent pain in the axillary glands, in which an abscess is often formed.

In children the umbilical region generally suffers, with a fatal event.

If in a day or two the tumour subsides, the heat and pain cease, the rosy colour turns yellow, the cuticle breaks and falls off in scales, the danger is over. When the erysipelas is large, deep, and falls upon a part of exquisite sense, the patient is not very safe. But if the red colour changes into black and blue, it will end in a mortification. If the inflammation cannot be dissipated, it will suppurate, and bring on fistulas and a gangrene. When the patient is cacochymic, the leg will sometimes swell three times as big as the natural size, and is cured with great difficulty. Those who die of this disease, die of the fever, which is generally attended with difficulty of breathing, sometimes a delirium, sometimes with sleepiness; and this in seven days time.

Let the patient's diet be only water-gruel, or barley-broth, with roasted apples. If he drinks any beer, let it be very small; and let him keep out of bed some hours in a day.

Take away 9 or 10 ounces of blood, and the next morning let the patient take the common purging potion.

It is a constant rule among practitioners, in all acute and eruptive fevers, to keep the body in a gentle diaphoresis.

refis. The same method is to be observed in this disease.

If the patient is plethoric, addicted to spirituous liquors, and more especially if the disease attack the head, bleeding is necessary.

It will be safest to avoid external applications, unless a powder made of elder-flowers and liquorice sprinkled on the part; or lime water, mixt with a fourth part of spirit of wine and camphire, dipping a linen cloth in it several times doubled, and applying it hot to the part.

An infusion of scordium, elder-flowers, and fennel-seed, drank in the manner of tea, is useful to expel the morbid matter.

If the disease does not yield to the first bleeding, let it be repeated: if that will not do, let it be reiterated twice more; one day being interposed between.

On the days free from bleeding, prescribe a clyster of milk and syrup of violets.

Some think purges not necessary in the beginning of this disease; but in an erysipelas of the head, when it affects the brain with a coma and a delirium, either the case is desperate, or cathartics will succeed. However, first apply blisters to the neck.

If, after all, the tumor remains, and begins to turn livid; if the pain lies deep, and seems to reach the periosteum, and the part has a tendency to ulcerate; then it will be proper to promote a suppuration; at the same time endeavouring to stop the progress of the putrefaction. For this purpose the common plaster will be proper, with a sufficient quantity of camphire and saffron. When there is matter that lies deep, the tumour is to be opened with a lancet, and the pus is to be got out by degrees, not all together.

When the abscess is in a glandulous part, and has degenerated into a fistulous ulcer, after evacuating the matter, a balsamic liquor is to be injected, made of tincture of St. John's wort, tincture of balsam of peru, choice myrrh, and a few drops of the spirit of turpentine.

When there is a mortification coming on, give things inwardly that resist putrefaction, as nitre and a little camphire, [or rather the Peruvian bark.] Outwardly apply a mixture of lime-water, camphorated spirit of wine and vinegar with litharge; as also tincture of myrrh, [or of myrrh and aloes] made pretty hot, with a linen cloth doubled, and often repeated.

In the scorbutic erysipelas, which continues for some time, it will be proper to give gentle laxatives and purifiers of the blood, with diaphoretics. After the body has been opened for some days, give diuretics and diaphoretics alternately for a considerable time; and for common drink, order a temperate decoction of mucilaginous woods and roots with bitters; particularly succory roots, dandelion-roots, and raisins.

Of the SYNCHUS, or Continual Fever without remission.

THIS fever, by some called *SYNCHUS*, by others a *CONTINUAL FEVER*, is an acute sanguineous fever, because it is raised by a congestion of the blood, chiefly in the nervoso-membranous parts; which, unless timely dissipated by the benefit of nature and art, produces a fatal inflammation.

It begins, in some, with a mild sense of cold, and is soon attended with very grievous symptoms, continuing without remission till the critical time, with a great and full pulse. If the blood is forced to the head, for it always affects one part more than another, the face will swell, the eyes will be red and full of tears; there is a pain in the head, with a pulsation of the temporal arteries, a vertigo, a sleepiness, torpor, or a raving. When the blood rushes impetuously into the ventricles of the heart and pulmonary vessels, causing a distention therein; then the breathing will be thick and difficult, with a straitsness of the breast, as also an anxiety and palpitation of the heart, attended with a loss of strength, and a dejection of the mind. A slight inflammation of the oesophagus, with a spastic stricture of the glands of the fauces, will cause thirst, dryness and blackness of the tongue. If the inflammatory congestion happens in the stomach, it will create a nausea, a reaching to vomit, and sometimes a hiccup. If in the intestines, there will be inflations grievously exasperating the disease, together with a costiveness, or an ejection of fetid excrements. If in the vessels proceeding from the mesaraic arteries and vena portæ, there will be a fixed pain at the first vertebra of the loins: if in the membranes of the spinal marrow, the patient will tumble and toss and lie irregularly in bed, and will have a torpor and languor of the limbs, sometimes attended with convulsions.

But all these symptoms never happen to all, nor is their violence constantly alike. Some distinguish this fever into the simple and putrid. The first is caused by a congestion of good blood in improper places. But when it attacks persons full of impure juices, who have been weakened by a preceding disease, constant anguish of the mind, excessive coition, or inordinate living, the symptoms are much more grievous, with loss of strength, and the disease will continue till the fourteenth or the twenty-first day, sometimes with eruptions, dusky or black spots, with immediate danger.

If the cause is not violent, this disease will often disappear, merely by the benefit of nature, on the fourth, seventh, or eleventh days, with a large sweat or bleeding at the nose, and, though very seldom, by a flux of the belly, unless it has something of malignity.

When the disease is rightly managed in the beginning, that is on the first, second, and third day, with bleeding and cooling things, and gentle diaphoretics, it will end on the fourth. But if the bleeding is omitted, or is too little, it may continue till the fourteenth or seventeenth day, with the more grievous symptoms, as also a delirium: but it will terminate at last by a sweat or looseness.

When it proves fatal, the patient generally dies of a sphacelous inflammation of the brain, or other parts, as the stomach or intestines.

The intentions of cure are, 1. To free the vital parts from too great a congestion of blood, which will either disperse a slight inflammation, or prevent a great one. 2. To appease the exaltation of the blood and the spastic affection of the system of the nerves. 3. To discuss the stagnating and corrupted fluids, and to restore a free circulation of the blood, chiefly to the surface of the body.

To answer the first intention, the patient must lose blood.

blood freely. Then the orgasm of the blood must be appeased with diluents, acids, and nitrous compositions. And certainly if any disease requires acids, and the juice of tart fruits, it is this, such as tamarinds, and the juices of currants, oranges, and lemons.

Take two pounds of water; rose-water, white sugar, and juice of oranges, of each one ounce.

The jelly of hartshorn made pretty thin, with the addition of orange-juice, sugar, and rose-water, will make a proper demulcent and cooling drink; or whey turned with juice of lemons or oranges.

To direct the motion of the blood to the surface of the body, gentle diaphoretics will be proper, such as the bezoardic or absorbent powders, sometimes alone, and sometimes with citron juice. Likewise infusions of the leaves of *veronica*, *scordium*, or *cardus benedictus*, with fennel-seed, drank in the manner of tea, especially to promote sweating on the fourth day, when the disease is like to terminate with this salutary excretion.

It will be necessary, whether this fever be simple or putrid, to keep the body open; for which purpose a clyster made of whey, honey, oil of sweet almonds, with a little nitre and salt, will be proper; for by this means the stricture of the intestinal fibres will be relaxed, and flatus will be discharged, which distend the colon. In the decline of the disease, when there are apparent signs of coction in the urine, a laxative of manna and cream of tartar, or cassia and rhubarb, will be of great use.

Of the Bilious Fever.

The bilious is a kind of a burning fever. It begins with intense heat, thirst, anguish, and inquietude. There is likewise a vomiting, or a perpetual reaching to vomit, with frequent bilious stools, a coldness of the extremities, internal heat, and cardialgic anxiety. This fever is either acute, or very acute. In this the symptoms are more violent, the bilious purging upwards and downwards is very plentiful, joined to a *cardialgia* with fainting. It generally kills before the seventh day, with an inflammation of the stomach and duodenum; the signs of which are, a fixed igneous heat about the *præcordia*, with a coldness of the extremities, high inquietude and anxiety, a hiccup, and a plentiful eructation of bile and salivary liquor, a jaundice-colour of the countenance, and a hippocratic face.

Some are not so acute, but run a greater length, with now and then a remission, and perhaps an intermission, and have an exacerbation, with vomiting, anxiety, and coldness every other day, or every third day, and ought to be called continual quotidian or tertians.

It is caused by a bilious fluid secreted plentifully in the liver, and poured out into the stomach and duodenum, where by its acrimony and corrosiveness it stimulates the nervous unities, corroding and inflaming them; whence the symptoms proper to this fever arise, such as a burning heat, a cardialgic anxiety, a nausea, a reaching to vomit, and a violent purging upwards and downwards.

Hoffman, in the cure of the bilious fevers mentioned by him, would have the caustic acrimony of the bilious juices abated and sheathed by absorbent powders and nitre, which should be taken in a sufficient quantity of a liquid,

and often repeated. He likewise recommends emulsions of almonds, of the cold seeds; elder-flower water, rose-water, &c. as also jellies of hartshorn, milk and water, oil of sweet almonds, sweet whey, chicken-broth.

After these things, medicines must be given to restrain the impetuous bilious excretions, and to abate the too quick systaltic and peristaltic motion of the biliary ducts, and to prevent the too great excretion of the bile.

In the cure of the Bilious Fever of the camp, Pringle, before it becomes continual, depends on the proper use of evacuations, the neutral salts, and the bark. Bleeding is the first thing to be done in every case, and is to be repeated once or oftener, according to the urgency of the distemper. The vernal and later autumnal remittents are accompanied with rheumatic, pleuritic pains, and other symptoms of high inflammation, which require more bleedings than the intermediate season. To omit this, and give the bark too soon, will bring on an inflammatory fever. A vein may be opened safely either during the remission, or in the height of the paroxysm.

After bleeding, give an emetic in the remission or intermission of the fever, and rather soon after a paroxysm than before one. But emetics do harm when the stomach is inflamed, or when the disease has continued some time, and has assumed the type of a continual fever. However, we may safely give one when the fever intermits, or has considerable remissions. Ipecacuanha is safest, but antimonials most efficacious. If the remissions are small, or the fever great, or there is a tendency to vomit, the former is best. But when the remissions are distinct, or the remission perfect, the latter should be preferred; or it may be joined to the former; that is, two grains of tartar emetic, with a scruple of the powder of ipecacuanha. Those vomits are best which produce stools, especially if they procure a plentiful discharge of corrupted bile upwards or downwards.

If the body continues costive, a laxative will be proper, especially if there is a tenesmus, or pains in the bowels. The saline draught, with salt of wormwood and lemon-juice, will bring the fever sooner to regular intermissions.

Whenever the sweats are not profuse enough in proportion to the fits, the quantity of an ounce of *spir. Mindereri* may be given, divided into two or three draughts, before they go off. It promotes a plentiful diaphoresis, without heating.

As the fevers are never without an inflammation in the beginning, and then rarely have complete paroxysms, the bark is not to be given till the urine breaks, and there are entire short intermissions; nor yet before bleeding, as was observed above; nor before the first passages have been cleaned; otherwise the fever will return, or a tympanitis will be produced.

It is best to give the bark in substance in Rhenish wine; or an ounce of it may be made into an electuary, with syrup of lemons, and a dram of sal ammoniacum. If the patient has not been purged, it will be proper to add as much rhubarb as will keep the body open for the first two or three days of using that medicine. It is chiefly useful when the bilious humours abound, as they mostly do in marshy countries. If the paroxysms are quotidian, and the

the intermissions short, it may be necessary to give the bark before the sweating is quite over.

If the disease has been neglected in the first stages, or if after the remissions or intermissions it changes to a continual fever, with a full and hard pulse, a vein must be opened. But if there is a pain in the head, or a delirium, and the pulse small, it will be best to apply leeches to the temples. But whether the patient is bled or not, blisters are the best remedy. If the *prime viæ* are loaded, clysters or a laxative may be proper; but neither vomits nor purges; nor are those to be repeated without caution. To these remedies the saline draught may be added.

Sweating is the proper crisis: it is never to be promoted by theriaca or volatiles; but when the pulse sinks, and petechiæ, or other symptoms appear, it will be proper to use the warmer alexipharmics, and to treat the disease like a malignant fever.

A looseness is the least favourable crisis: yet if there are colic pains, or a tension of the belly, attended with dryness of the skin, it will be proper to procure stools by a clyster, or a gentle laxative, such as the infusion of rhubarb with manna; which is to be repeated as the patient can bear it.

Of a CAUSUS, or BURNING FEVER.

THE principal symptoms of a causus are, a heat almost burning to the touch, most remarkable about the vital parts, but more moderate towards the extremities, which are even sometimes cold: the breath is extremely hot; there is a dryness of the whole skin, nostrils, mouth, and tongue. The respiration is thick, difficult, and quick; the tongue is dry, yellow, black, parched, and rough; the thirst is unquenchable; there is loathing of food, a nausea and vomiting; an anxiety, inquietude, and great lassitude: a little cough, a shrill voice, a delirium, a phrensy, a continual watching or a coma, convulsions, and on the odd days an exacerbation of the fever.

In this temperate climate these sort of fevers are very rare; those that are more common among us are the burning fanguineous, or the continual bilious fevers without remission.

This begins without any remarkable coldness or shivering, with great heat, thirst, watching, anxiety and inquietude. In fanguineo-bilious constitutions, and in bodies full of hot bilious blood, they terminate in critical days in health or death, being first preceded with a shaking. They terminate in a salutary manner, with a sweat or a bleeding at the nose.

On the third and fourth day it often proves mortal; it seldom exceeds the seventh, if violent.

It is often terminated by an hæmorrhage; which if small on the third and fourth day, it is a fatal sign. It is best if it happens on a critical day.

A solution of this fever on a critical day, may also be by vomiting, stool, sweat, urine, or spitting thick phlegm. If the exacerbation of this disease happens on the second or fourth day, it is a bad sign; on the sixth, not so bad.

The urine black, small in quantity, and thin, is fatal; so is spitting or pissing of blood. A difficulty of swal-

lowing is a bad sign; but the worst of all is coldness of the extreme parts. The face red and sweaty, is bad; a parotis not tending to suppuration is fatal; the body too loose is fatal. A tremor turning into a delirium is mortal; it often changes into a peripneumony with a delirium. When this disease succeeds gripings of the bowels, it is worst of all.

A critical determination of this fever is usually preceded by a rigor, or shaking.

THE CURE of a burning fever is most easily obtained in a pure, cool air, frequently renewed: The patient must not be oppressed or stifled with bed cloaths, but should sit up often. He should drink plentifully of soft, sub-acid, aqueous, and warm liquors. His diet should be light, made of pearl barley, oatmeal, and sub-acid fruits.

Bleeding is necessary at the beginning, if there is a plethora, or signs of a particular inflammation, or the heat is intolerable, or the rarefaction too great, or a revulsion necessary, or the symptoms urgent, in which circumstances the disorder is hardly to be vanquished by any other remedies.

Soft, diluting, laxative, antiphlogistic cooling clysters, are to be repeated as oft as the heat, costiveness, and revulsion require them.

The whole body is to be moistened by receiving into the nostrils the steams of warm water; by washing the mouth, throat, feet, and hands, with the same; by fomenting with warm sponges the places where the vessels are most numerous, and most exposed to the touch.

The medicines should be aqueous, soft, nitrous, gratefully acid, gently laxative, not promoting sweat and urine by their acrimony, but by their plenty; such as remove the contraction of the fibres, resolve the thickness of the humours and dilute, and temper their acrimony.

To appease thirst in this disease, and to moisten the tongue and parched fauces, there is nothing better than sweet whey, in a quart of which half a dram of pure nitre has been dissolved. Small draughts of this, a little cool, may be drank frequently, which will likewise extinguish the pernatorial heat. The mouth and throat may also be washed with water, mixt with syrup of mulberries and nitre.

Purgatives are dangerous before the crisis, but clysters may be used, made of milk, honey, and a little nitre. After the crisis, which is known by the sediment in the urine, laxatives made with tamarinds, manna, rhubarb, raisins, or cream of tartar, are absolutely necessary.

Of the Burning Bilious FEVER, or YELLOW FEVER of the West Indies.

THE yellow fever begins with a momentary chilliness and shivering, which is soon succeeded by a burning heat all over the body, but is felt more intensely about the præcordia. The pulse is high, strong, and rapid; the eyes are heavy; with a throbbing pain in the head, and a violent bearing of the temporal arteries, and a thick, laborious respiration: There is a nausea, and reaching to vomit; and when any thing is thrown up, it is of the bilious kind: Besides these, great anxiety, pain in the back and loins, and an uneasy lassitude in all the limbs.

† X About

About twelve hours after the invasion, the tongue is dry, harsh, rough, and discoloured, with insatiable thirst; there is a forensis all over the body, great restlessness, and a delirium.

In the last stage the patient labours under a great coma, oppression of the præcordia, heaving of the lungs, an interrupted respiration, tremblings of the tendons, convulsions, and cold clammy sweats.

It usually terminates in a favourable crisis, or the death of the patient, about the fourth day after the attack.

The regular crisis generally discovers itself by a suffusion of the bile all over the surface of the body about the third day. The saffron tincture is frequently discovered in the eyes twelve hours after the invasion: the sooner it appears, the more favourable is the prognostick.

If the jaundice comes on too soon, it is bad; if with livid spots, which sometimes, though rarely, appear, it is fatal. If the skin continues obstinately dry and rough, the case is dangerous; and the more so, the longer it continues; for these very seldom recover, be the pulse ever so good. The pulse is not to be depended on; for many have a good pulse a few hours before death. If the vomitings are incessant, grow darker, and the hiccup comes on, it is generally fatal. If the face is greatly flushed, and the vessels of the white of the eye are turgid with blood, as in an ophthalmia attended with a phrenzy, the patient is likely to die in a very little time, especially if the skin is dry.

But if the head continues clear, the pulse becomes soft, the pains, nausea, and anguish are relieved by bleeding; as also if the humours vomited up are carried downwards by laxatives; if then the inquietude ceases, the skin grows soft and moist, and the patient has better spirits; it is probable he will recover.

Bleeding is the first thing to be done, more or less, according to the force of the disease and the strength of the patient; and, if the symptoms continue in their full vigour, should be repeated once in six or eight hours, lessening the quantity proportionably each time.

After the first bleeding, give a vomit of ipecacuanha, quickened with three or four grains of emetic tartar, (or rather two grains,) which will bring up a great quantity of yellow, porraceous, and sometimes blackish bile, and carry the humours downwards.

After this the patient may drink plentifully of diluting, refrigerating, and subacid liquors, made with oranges, lemons, tamarinds, spirit of sulphur, spirit of vitriol, and such like, in barley-water, spring-water, or other thin and cooling vehicles. He may likewise be allowed tartish juicy fruits; as ananas, granadillos, Barbadoes cherries, and water-melons; as also plantains, and bananaes, roasted for food, jelly of guavaes, &c.

Cooling testaceous powders are likewise very beneficial.

Towards the evening it will be necessary to inject a clyster, made of the common decoction, with half an ounce of cream of tartar, an ounce of manna, or an ounce of pulp of cassia added to it.

When the operation of the clyster is over, paregorics will be proper, as thus:

Take 2 ounces of mint-water, one ounce of cinnamon

water, 25 drops of the tinctura thebaica, and a sufficient quantity of sugar.

The room should be kept cool, and sprinkled with vinegar, rose water, and cooling herbs. Fresh air should be admitted, but not to blow directly on the patient's body.

Blisters are also of great efficacy at this juncture; which if applied before it be too late, a coma, the deadly symptom of this distemper, very rarely ensues.

The patient's diet should be nothing but thin panada and water-gruel, gratefully sweetened and acidulated.

Besides plentiful and frequent draughts of cooling liquor, the patient should be allowed preserved tamarinds, slices of lemon with a little sugar; but above all, pen-guins, which by their sharpness penetrate the thick tenacious scurf, whereby the glands of the mouth will be unloaded. Opiates must also be used in larger doses than in Europe.

Cooling and lenient clysters must also be repeated every eight hours.

When the patient begins to be comatose, the third and last stage of the disease is advancing; in which are, difficulty of breathing, oppression of the præcordia, convulsive twitching of the tendons, interruption of the pulse, and at length its total cessation.

In this case, a complete set of blisters must be immediately applied, or the old ones renewed; which must be laid to the nape of the neck, on the wrists, thighs, and legs, and a large one on the crown of the head. To the soles of the feet may be laid a cataplasm of salt herrings and mustard.

With regard to the urgent symptoms; pains of the head, watchfulness, and deliria, are to be relieved by emollient and laxative clysters, gentle purgatives, cupping with scarification, opening the frontal vein, lotions of the feet, and narcotics.

Blisters are also useful for the same purpose.

Convulsions require much the same treatment externally; and internally, *aurum muscivum*, (the dose from four grains to a scruple.) To restore the strength of the patient, little more is required than a stomach purge or two, mild and agreeable bitters, and a restorative regimen of broths, jellies, and white meats.

If the yellow tincture remains upon the skin, give a vomit of ipecac. and a purge or two with the decoction of senna, tamarinds, &c. and allow the use of lemons, oranges, and other acid fruits. If this disorder proves obstinate, treat it as the jaundice.

Of the SENEGAL FEVER.

THE fever which chiefly prevails in this country in the months of July, August, and September, is of the worst kind. It usually begins with drowsiness, lassitude, and great rigors, which continue frequently three or four hours, and are succeeded by intense heat and sweats. For three or four days it remits, and both the shiverings and hot fits become more moderate. During this period, the pulse is quick and low; but afterwards becomes fuller, unless some evacuation intervene. At this time profuse sweats are easily brought on; in which case there are little hopes of recovery. A parched, dry skin, is as bad a symptom, if it continues more than a day; for an

intermitting

intermitting pulse and a delirium succeed, and continue for seven or eight days, the frequency of the intermissions increasing every day: but if a general moderate moisture comes one at this, or any other time of the disorder, and continues, the patient recovers. A violent pain in the head and back, and difficulty of breathing, are general complaints. Sudden languors, and bilious vomitings, are frequent from a great part of the time.

Some are taken with a great heat, and a strong quick pulse, without any shiverings or remissions, as abovementioned. In this case the patient sooner dies upon the appearance of bad symptoms, and is longer in recovering upon the appearance of good ones.

The loss of eight or ten ounces of blood, in the first attack of these fevers, has sunk the pulse beyond a possibility of raising it afterwards, and that even in plethoric habits, attended with great pains of the head. It is, indeed, surprising how little these fevers will bear of evacuations of any kind, especially bleeding.

After profuse sweats, the pulse becomes extremely slow; and, though the sweating goes off, continues so for two or three days, with anxiety and restlessness; after which the pulse grows quick, the skin parched and hot, and a series of bad symptoms comes on.

The sick are always comatose and stupid; which symptom is little dangerous when attended with a warm moisture on the skin, but otherwise it is generally fatal.

It is of great consequence to keep up the pulse; but here the common cordial medicines are ineffectual; yet the decoction of the bark, with the camphorated julep, and spirit of vitriol, answers this purpose effectually, so as to render any other medicine unnecessary, except occasionally a gentle emetic or laxative.

Of the INFLAMMATION of the STOMACH.

THE inflammation of the stomach is known by a burning, fixed and pungent pain in the stomach, which is exasperated at the instant any thing is taken into it; and is succeeded by a most painful vomiting and hiccup. There is always a violent internal heat, high anxiety, and a grievous pain about the præcordia, chiefly at the pit of the stomach, an acute, continual fever, great thirst, difficult breathing, inquietude, tossing of the body, coldness of the extreme parts, a hard, contracted, quick, and sometimes unequal pulse.

It may be distinguished from other disorders of the stomach; for in the cardiagia, there is also a great anxiety about the præcordia, a pressing acute pain reaching to the back, a coldness of the extremities, a constant stimulus to vomiting, with inquietude: But the heat in the region of the stomach is not so violent, nor is the thirst and dryness of the tongue so great, nor the pulse so quick and contracted, and the stomach can better bear and retain any thing taken inwardly; nay, is frequently relieved thereby. An inflammation of the intestines has a pain or gripes more about the region of the navel, with frequent, frothy, bilious stools, or a little bloody, with a heat over all the surface of the body, and a quick large pulse: Whereas in this disease the extremities are cold.

If it be caused by drinking cold liquors when the body

is hot; or from an effusion of the bile after violent commotions of the mind; the danger is not very great, as there will be room for suitable medicines to take effect: But that which arises from drastic purges, sharp emetics, or caustic poisons, kills quickly without speedy assistance. This disease likewise often proves fatal to the old, the infirm, the scorbutic, and persons full of grief, as also in the end of acute diseases.

When there is a restless tossing of the body; when liquids are immediately thrown up; when there is a hiccup, a fainting, an hippocratic face, an intermitting pulse, and convulsions, a fatal mortification will soon terminate the patient's life.

This disease, if not suddenly cured, is generally mortal: And therefore, as soon as it is discovered, plentiful bleeding is necessary, and must be repeated as the violence of the symptoms increaseth. Let the drink be very soft, antiphlogistic, and emollient; as also clysters of the same kind.

The patient should totally abstain from every thing that is acrimonious; even the cooling, nitrous salts, which are beneficial in other inflammations, irritate too much. Vomits, cordials, and spirituous liquors, are little better than poison.

Aliments should be given frequently, and by a spoonful at a time; for any distention increases the inflammation. A thin gruel of barley, oatmeal, whey, with very little sugar or honey, or chicken-broth, are proper aliments; whey-emulsions, barley-water, emollient decoctions, are proper drinks.

The indications of cure are, 1. To open the obstructions caused by tenacious juices impacted into incongruous vessels; 2. To remove the spastic strictures which contract the vessels, and to restore the equable and natural progress of the blood through the substance of the stomach. These ends are to be obtained by *diluents, humectants, demulcents, antispasmodics*, and things that restrain the heat which thickens the fluids, and relax the constricted fibres.

But as there are more causes than one that produce an inflammation, they will require different remedies to bring about a cure.

Therefore, if it be owing to a caustic, septic, arsenical poison, or a strong emetic or cathartic, or to metallic medicines ill prepared, and thence the inflammation; oily fat things are proper, as new milk, cream, oil of sweet almonds, or olive-oil taken often and plentifully.

If from a spasm, succeeding a violent commotion of the mind, then a nitrous absorbent powder will be proper, in an emulsion of white poppy seeds. When the spasm is appeased, rhubarb with raisins will be necessary to carry off the bilious fœces.

When an eruptive matter is repelled and causes this disease, use emulsions of the greater cold seeds, with temperate bezoardic powder; now and then adding a little nitre and a small matter of camphire.

If from a caustic bile, as in the cholera morbus, an inflammation is apprehended, earthy absorbents and hartshorn philosophically prepared should be given, with gelatinous decoctions of calves and neats feet, or hartshorn-jellies.

jellies and water-gruel. Outwardly, the following liniment is useful in all cases:

Take of oil of sweet almonds 2 ounces, and a dram of camphor; mix and make them into a liniment, to be applied warm to the stomach.

Of the QUINSEY.

A QUINSEY is an inflammation of the fauces, with a burning pain, tumor and redness; a difficulty of breathing or swallowing; and a fever, proceeding from a stasis of blood, or a viscid acrid serum in the sanguineous or lymphatic vessels.

It begins with a fever, which is followed with a pain and inflammation of the fauces, causing the uvula, tonsils, and larynx to swell; whence great difficulty of breathing and swallowing ensues.

This disease may be seated at the root of the tongue near the *os hyoides*; the *foramina* of the nostrils opening to the bone; the beginning of the *esophagus*; the muscles of the pharynx; the internal and external muscles of the larynx; the greater and lesser glands; the tonsils, or the muscles moving the jaws.

When a quinsy affects the internal muscles of the larynx, and there is no outward redness about any part of the neck, but a burning pain inwardly, a loss of voice, and great difficulty of breathing; it often kills in twenty-four hours. This is called a *kynanche*. When it is seated in the internal muscles of the pharynx, it is called a *synanche*; in which there is no external tumor and redness, but a great difficulty of swallowing and breathing, and whatever is drank returns through the nose. When there is an outward tumor and redness, and the external muscles of the pharynx are affected, it is a *parasyanche*; when the external muscles of the larynx, a *parakynanche*.

A quinsy is likewise distinguished into the true and spurious. The true arises from the stasis of the blood; the spurious or balstard from a congestion of the serum. The former is acute, always attended with a rigor and a fever. The latter has rather a lymphatic or catarrhal, than an acute fever. The first has not only a burning, pricking pain in the inner parts of the fauces, but the tongue is turgid with blood, and of a dark reddish colour; the face is likewise red; there is a great pulsation of the temporal arteries; sometimes a head-ach, a torpor of the senses; sometimes fainting.

When it is very violent, there is a difficulty of breathing, high anxiety, and coldness of the extremities; and is very dangerous, requiring speedy help. But in the spurious, those symptoms are either absent, or more mild; nor is the danger so great.

This disease may be caused by a suppression of some usual sanguineous evacuation; by admitting the cold air after a strong sudorific has been taken; and by lying in rooms new plastered or white-washed. Some caustic poisons affect the throat more than other parts. White hellebore attacks the fauces, and brings on a strangulation. The same ensues from the *solanum furiosum*, and the bite of a mad dog. The fumes of arsenical and mercurial minerals, as also the vapours of mineral spirits, will have the same effects.

It sometimes comes on spontaneously, and is again the symptom of another disease, as the diarrhoea and dysentery, especially if the flux is hastily stopped. It has happened from the striking in of an erysipelas; or sometimes from the gout being injudiciously treated with topicks; as also from the small-pox, or a malignant or pestilential fever. The cause of the symptomatic disease is costiveness, or suppressed perspiration, or the striking in of eruptions. When it is epidemic, it has something of malignity.

When the swelling, pain, and redness, appear more outwardly, and vanish by degrees, it is a sign of a happy solution of the disease. But when the external swelling suddenly disappears, without a mitigation of the symptoms, it shews the morbid matter to be translated elsewhere, and will change to a phrenzy or peripneumony. Or this disease may terminate in a suppuration or gangrene, or a schirrus. A frothing at the mouth, the tongue vastly swelled, and of a purple, blackish colour, portend death.

In these inflammations a slight diarrhoea relieves: Therefore aliments which promote it are useful, as tamarinds infused in whey; decoctions of farinaceous vegetables moderately acidulated, and such as abound with a cooling nitrous salt, are proper. Burnet is said to be a specific in this case. Mulberries are beneficial, and all acids.

The mouth and throat must be kept moist, and the nose clear, that the air may have clear passage through it. When the patient cannot swallow, he may be nourished by clysters.

Take away blood plentifully from the arm, and afterwards open a sublingual vein; but bleeding in the jugular yields the best assistance, and is much more safe. If the symptoms continue to be very urgent, the bleeding may be repeated in six or eight hours time, till they begin to be more mild.

After the first bleeding, lay a strong and large blister on the fore-part of the neck, or a piece of flannel dipt in the volatile liniment.

Then let the parts inflamed be touched with the following mixture:

1. Take a sufficient quantity of honey of roses and spirit of sulphur. Mix them.

Then the following gargle is to be used, held in the mouth till it is hot before it be spit out; which is to be repeated pretty often:

2. Take a pound of barley-water, 8 ounces of honey, and 2 drams of spirit of sal armoniac. Mix them.

Emollient steams, or even the steam of hot water taken in at the mouth, are beneficial.

If the patient is not able to swallow any nourishment,

3. Take ten ounces of beef-tea, 10 grains of nitre, and 6 drops of spirit of salt. Mix and make them into a clyster.

Let it be injected every eighth hour, after the belly has been cleansed with a purging clyster.

If the tumour tends to a suppuration, it is best promoted by holding fat, dried figs in the mouth; and when the tonsils are full of an inflammatory ichor, honey of roses mixt with spirit of vitriol, and often applied to the part with a pencil, is excellent.

That inflammatory pain which arises from a sharp salt serum in the glandulous parts of the fauces, with redness, and a copious flux of saliva, but without a fever, may be cured with a gargle of brandy alone. An inflammation of the fauces is sometimes cured with ten drops of camphorated spirit of wine, in which a grain of nitre has been dissolved, and suffered to pass slowly down the throat.

The acute and inflammatory quinsy may be defined, "An inflammation of some part or parts, either within or contiguous to the throat, rendering deglutition painful, or impracticable; and, when it is of the most dangerous kind, likewise affecting respiration."

When only swallowing is impaired, the parts inflamed may be the tonsils, the velum palati, and uvula, the muscles of the pharynx, and those of the larynx, which raise it or pull it down in deglutition, but whose action is not concerned in moderating the aperture of the glottis; while the larynx itself and the aspera arteria remain free.

But when the respiration is pinched, besides other parts, these muscles, which are employed in opening and shutting the glottis, must be inflamed; and likewise, probably the inner membrane of the larynx, and those muscles and fibres that join the rings of the aspera arteria together: And sometimes these minute and remote parts are affected without any redness or tumour, either within the fauces, or outwardly on the throat: This kind of quinsy is the most dangerous and suddenly destructive of all.

The practitioner in every kind of quinsy ought to look carefully into the mouth and fauces, in order to discern where any redness and tumour is; that by comparing the appearance of the parts with the functions impaired, he may be enabled to form the better judgment with respect to the seat of the disease, the prognosis, and method of cure.

If the breathing is remarkably affected, there is absolute necessity of applying all the most efficacious remedies with the greatest briskness and speed possible. These are plentiful and repeated bleedings, a large blister between the scapulæ; fomentations and cataplasms outwardly; steams to be received into the throat, the best ingredient in which is vinegar; smart, but cooling purges; or, if these cannot be got down, clysters of the same kind; bathing the feet and legs in warm water, and even semicupia not made too hot, for fear of raising the pulse too high.

But even though the respiration should not be affected at first, if the symptoms are otherwise violent, remedies ought to be smartly and quickly applied to prevent suppuration. For when the inflamed part tends to suppuration, the tumour keeps increasing; and when the pus is actually formed, the bulk may be so enlarged as to endanger suffocation, or the patient may be starved by a total privation of swallowing; so that suppuration should always be prevented, if possible.

If in the course of the distemper the patient should run a risk of being suffocated, the operation of bronchotomy becomes necessary. See SURGERY.

Of the Malignant QUINSEY, or Putrid SORE THROAT.

This disease generally comes on with such a giddiness of the head, as often precedes fainting, with a chilliness or shivering like that of an ague fit, followed by great heat; and these alternately succeed each other for some hours, till at length the heat becomes constant and intense. The patient then complains of an acute pain in the head, of heat and soreness, rather than pain, in the throat; stiffness of the neck; commonly great sickness, vomiting or purging, or both. The face soon after looks red and swelled, the eyes inflamed and watery as in the measles; with restlessness, anxiety, and faintness.

It frequently seizes the patient in the fore-part of the day; and as night approaches the heat and restlessness increase, continuing till towards morning; when after a short, disturbed slumber, the only repose during several nights, a sweat breaks out, which mitigates the heat and restlessness, and gives the disease sometimes the appearance of an intermittent.

If the mouth and throat be examined soon after the first attack, the uvula and tonsils will appear swelled; and these parts together with the velum pendulum palati, as well as the cheeks on each side, near the entrance into the fauces, and as much of the fauces and the pharynx behind as can be seen, appear of a florid red colour. This colour is commonly most observable on the posterior edge of the palate, in the angles above the tonsils, and upon the tonsils themselves. Instead of this redness, a broad patch, or spot, of an irregular figure, and of a pale white colour, surrounded with a florid red, is sometimes to be seen. This whiteness is commonly like that of the gums after having been pressed with the finger; or as if a matter ready to be discharged lay underneath.

Generally on the second day, the face, neck, breast, and hands, are of a deep erysipelatous colour, with a sensible tumefaction. The fingers are so frequently tinged in a remarkable manner, that it has been no hard matter to guess at the disease from a bare sight of them.

A great number of small pimples of a more intense colour than that which surrounds them, appear on the arms and other parts. Where the redness is least intense, they are larger and more prominent, which is generally on the arms, breast, and lower extremities.

As the skin becomes red, the sickness commonly goes off, and the vomiting and purging cease.

The appearance in the fauces continues the same, only the white place becomes of a more opaque white, and is discovered to be a slough, concealing an ulcer of the same dimensions. These ulcerations are generally first discernible in the angles above the tonsils, or on the tonsils themselves. They are also often seen in the arch formed by the uvula and one of the tonsils; on the pharynx behind, on the inside of the cheeks, the basis of the tongue, which they cover like a thick fur. Where the disorder is mild, there is only a superficial ulcer, of an irregular figure, in one or more of those parts, scarce to be distinguished from the sound part, but by the inequality of its surface. Likewise the redness and eruption do not always appear, and in some not till the third, fourth, or fifth day, or later.

The parotid glands on each side commonly swell, grow hard, and are painful to the touch; If the disease is violent, the neck and throat are surrounded with a large œdematous tumour, sometimes extending itself to the breast, and by straitening the fauces increase the danger.

Towards night the heat and restlessness increase, and a delirium frequently comes on. This happens to some on the first night. It is very remarkable, that the patient commonly returns a proper answer to any question, but with unusual quickness; yet when they are alone, they generally talk to themselves incoherently. However, at the first tendency to this disorder, they affect too great a composure. This for the most part happens to those that sleep but little; for some are comatose and stupid, and take but little notice of any thing that passes.

They continue thus for three, four, or more days, commonly growing hot and restless towards the evening. These symptoms and the delirium increase as the night comes on: a sweat, more or less profuse, breaks out towards morning; and from this time they are easier during some hours, with a faintness, which is their chief complaint.

Some grow easier from the first day of the attack; others have symptoms of recovery on the third, fourth, or fifth day. First the redness of the skin disappears; the heat grows less; the pulse, hitherto very quick, becomes slower; the external swellings of the neck subside; the sloughs in the fauces are cast off; the ulcerations fill up; the patient sleeps without confusion, is composed when awake, and his appetite begins to return towards more solid nourishment.

The pulse, during the course of this disease, is very quick, beating frequently 120 times in a minute. In some it is hard and small, in others soft and full, but not so strong and firm as in genuine inflammatory disorders.

If a vein be opened soon after the distemper comes on, the blood generally appears of a fresh and florid red: the *crassamentum* is rather of a lax, gelatinous contexture, then dense or compact; the serum is yellow and in a large proportion.

The urine is at first crude and of a pale whey-colour; as the disease advances it turns yellow, as if bile was diluted in it; and soon after any signs of recovery appear, it commonly grows turbid, and deposits a farinaceous sediment.

They seldom have any stools if the symptoms are favourable, from the time the purging, which generally attends the accession, ceases. This discharge is remarkably bilious, yet without pain.

The thirst is commonly less than in other acute diseases; and the tongue generally moist, but not furred. Some have it covered with a thick white coat, and complain of soreness about the root of the tongue.

Though the uvula and tonsils are sometimes so much swelled as to leave a very narrow entrance into the gullet, and this entrance frequently surrounded with ulcers, or sloughs; yet the patient swallows with less difficulty and pain than might be expected. Soon after they are taken ill, they frequently complain of an offensive putrid smell, which often occasions sickness before any ulcerations ap-

pear. The inside of the nostrils, in those that have this disease severe, frequently appears, as high as can be seen, of a deep red or almost livid colour. After a day or two, a thin corrosive fumes, or with it a white putrid matter, of a thicker consistence, flows from it, so acrid as to excoriate the part it lies upon any considerable time. This is most observable in children, or in young and very tender subjects; whose lips are likewise frequently of a deep red, or almost livid colour, and covered on the inside with vesicles containing a thin ichor, which excoriates the angles of the mouth and cheeks where it touches them.

This acrid matter seems to pass with the nourishment into the stomach, especially of children; for if they get over the disease, a purging succeeds, yet attended with symptoms of ulcerations in the bowels: these, after great pain and misery, at length die emaciated.

The patients sometimes bleed at the nose towards the beginning of the disease; and the menses often appear in the female sex, if they are of age, soon after they are seized, though at a distance from the time of their regular period. It brings this evacuation upon some that never had it before. This flux, in full strong habits, is seldom attended either with benefit or with manifest ill effects, unless very copious; yet sometimes it occasions great faintness, and an increase of the other symptoms. Hæmorrhages of the nose and mouth have carried the patient off suddenly: but this does not happen till several days after the attack; and perhaps may be owing to the separation of a slough from the branch of an artery.

Children and young persons are more exposed to this disease than adults; girls more than boys; women more than men; and the infirm of either sex than the healthy and vigorous. Very few grown people have it. When it breaks out in a family, all the children are commonly infected with it, if the healthy are not kept apart from the sick. And such adults as are frequently with them, and receive their breath near at hand, often undergo the same diseases.

With regard to the cure, bleeding is generally prejudicial. Some admit of it at the first attack without any sensible inconvenience; but a repetition of it in the mild cases seldom fails to aggravate the symptoms; it has sometimes produced very fatal consequences. It increases the heat, restlessness, delirium, and difficulty of breathing; nor do the swelling of the fauces, tonsils, &c. receive any benefit therefrom. On the contrary, though the fullness of these parts decreases, yet the sloughs thicken and change to a livid black colour, the external tumour grows large, and the spitting commonly diminishes. Indeed, the heat and quickness of the pulse may seem to abate at first by this evacuation; but they commonly return with greater violence, the patient is seized with a difficulty of breathing, falls into cold sweats, a stupor, and dies suddenly.

Nor is purging more beneficial; even gentle cathartics have brought on very dangerous symptoms. Upon procuring a few stools with manna, especially when the disease has continued two or three days, the redness of the skin has disappeared, and the flux to the throat has been surprisingly increased. If this discharge by stool continues,

tinues, the swelling of the neck commonly grows larger, the fauces become flaccid, dry and livid; and the patient a few hours after this expires.

Nitrous cooling medicines frequently produce the like effects; they increase the faintness which accompanies this disease, and either dispose the patient to copious sinking sweats, or stools.

Upon the whole, it appears, that all evacuations which tend to lessen the natural strength of the constitution, are injurious; and those persons are commonly in the greatest danger who have been previously indisposed, or their strength impaired by grief.

If the purging, therefore, continues long after the first exacerbation of the disease, it is a dangerous symptom; for though it may sometimes be restrained for the present with opiates or astringents, yet it commonly returns with greater vehemence when their efficacy ceases, and in a short time exhaults the small degree of strength remaining. In this case they generally sweat very little; the fauces appear dry, glossy, and livid; the external tumour grows large; they void their excrements without perceiving it, and fall into profuse sweats; the respiration becomes difficult and laborious, the pulse sinks, the extreme parts grow cold, and death, in a few hours, closes the scene. The eye loses its lustre, and becomes opaque and dim, sometimes several hours before death.

A copious flux of pituitous matter to the glands and other parts about the fauces, have seemed sometimes to be the cause of sudden death.

It is necessary that the patient should be kept in bed as much as may be, though the disease should seem to be slight; for a purging has come on for want of care in this respect, the redness of the skin disappeared, and a disorder which with confinement alone would probably have gone off in twice twenty-four hours, has been rendered tedious and difficult.

At the first, while the sickness and vomiting continue, it will be best to promote the discharge, by giving an infusion of green tea, camomile flowers, carduus, or a few grains of ipecacuanha.

If the symptoms do not abate by this means, give small draughts of mint-tea, with a sixth part of red port, frequently, together with some warm and cordial aromatic medicine, every four or six hours.

The diarrhoea, as well as vomiting, generally ceases in less than twelve hours from the first attack: If it continues longer, it is necessary to check it; otherwise it occasions great faintness, sinks the strength, and in the end produces dangerous consequences. The aromatic cordials commonly take off this symptom, if given plentifully, and the vomiting likewise.

Patients generally complain of an excessive faintness soon after they are taken ill. The urgency of this symptom seems to indicate the degree of danger; and an abatement of it is a pretty sure preface of recovery. Aromatic medicines are likewise found useful in removing this symptom. Wine may be given in small quantities in whey, or mint, baum, or sage-tea, barley-water, gruel, panada, sago, and the like; for it is not only an antiseptic, but a generous cordial. When the faintness is excessive, it may be given alone.

Blisters likewise relieve faintings; they may be applied with advantage to the usual parts, and to the neck on each side, from below the ear almost to the clavicle, as occasion requires.

With regard to the ulcers, which demand our early and constant attention: When the disease is of the mildest kind, only superficial ulceration is observable, which may escape the notice of a person unacquainted with it. A thin, pale, white slough seems to accompany the next degree; a thick, opaque, ash-coloured one is a farther advance; and, if the parts have a livid or black aspect, the case is still worse. These sloughs are real mortifications of the substance; since, whenever they come off, they leave an ulcer of a greater or lesser depth, as the sloughs are superficial or penetrating.

The thin, acrid ichor, which is discharged from under the sloughs, often proves of bad consequence, especially to children. If gargles are injected, they either prevent them from reaching the seat of the disorder with their tongues, or they swallow them and the putrid taint of the ulcers together; whence fatal purgings ensue, or fatal hæmorrhages from the penetrating gangrene. Those that have a plentiful discharge from the fauces, carrying off this ichor, are seldom attended with sickness, vomiting, or excessive faintness; and where there is little or no discharge, the symptoms are commonly most dangerous.

Hence the great advantage of gentle stimulating aromatic gargles appears; because they promote the discharge of pituitous matter, and, doubtless, some part of the corrosive fluid along with it. To which, if we add antiseptics and detergents, to check the progress of the mortification, and to cleanse the fordid ulcers, every indication will be answered.

When the disease is mild, the symptoms favourable, the sloughs superficial, order a gargle of sage-tea, with a few rose-leaves in the infusion. Three or four spoonfuls of vinegar may be mixed with half an ounce of the tea, with as much honey as will make it agreeably acid.

If the sloughs are large, and are cast off slowly, they may be touched with mel ægyptiacum, by means of an armed probe.

It is not uncommon for hectic heats, night sweats, want of appetite, and dejection of spirits, to attend those a considerable time who have had the disease in a severe manner. Asses milk commonly relieves them, together with a decoction of the bark and elixir vitrioli.

The cause of this disease seems to be a putrid virus, or *miasma sui generis*, introduced into the habit by contagion, principally by means of the breath of the sick person.

The intentions of cure in this disease is to keep up the *vis vitæ*; to encourage the cuticular discharges; and to conquer the spreading putrefaction. Therefore, all evacuations which lessen the strength, particularly bleeding and purging, and all the nitrous antiphlogistic medicines, are highly improper.

And since a laxity of fibres predisposes persons to receive this disease, it is manifest, both with regard to the preservation and cure, tonic medicines are indicated; and among those the bark justly claims the first place.

The

The only certain diagnostics of this disease are aphthous ulcers and sloughs on the tonsils and parts about the pharynx.

Most persons in the beginning have a nausea and vomiting, and some a looseness. Those who are colicive, have, upon the use of the gentlest ecoprotics, immediately been seized with a diarrhoea, difficult to restrain. All medicines which tend to move the belly, not excepting rhubarb, are extremely dangerous.

Those who have had the disease with most violence, have had the head always heavy and stupid, and the eyes foul and full of tears. Not a few have had the head covered with petechiæ and purple spots.

The first thing to be done is to order the hot steam of a boiling mixture, of vinegar, myrrh, and honey, to be received into the throat, through an inverted funnel. If it is necessary to make it still more penetrating, add some of the *spirit Mindereri*. This steam can scarce be used too frequently, provided it is received with a due degree of heat.

If the *prime viæ* seem foul, or much loaded, it may be necessary to begin the cure by cleansing the stomach with carduus tea, in which a little sal vitrioli is dissolved, and some other gentle and quick emetic. No other evacuation seems proper, and this is only to be used at the very beginning of the disease. If the physician is not called in soon enough, it will be necessary to begin immediately by giving the bark, joined with the *spir. Mindereri*.

The bark is most efficacious in substance; but when the strength of the patient is much reduced, and the digestive powers weakened, which is usual in putrid fevers, on the very first seizure, the decoction or extract may be thought preferable; but this last is seldom to be had genuine. In making the decoction, it ought to be done with as gentle a heat as possible, and then evaporate very slowly to procure the extract, lest it be burnt too, and that the volatile parts may fly off as little as may be.

In the use of the *spiritus Mindereri*, care should be taken that it be exactly neutralized; or rather, as the disease is putrescent, that it may incline towards the acid. This is particularly of use where the heat is very great, it being very attenuating and antiseptic.

When the putrefaction is sufficiently conquered, it will be necessary to cleanse the first passages with a small dose of rhubarb; which is to be repeated at proper intervals, continuing the bark, &c. on the intermediate days for a considerable time.

To complete the cure, the patient should enter into a course of balsamics, chalybeate waters, with elixir vitrioli, and the like, in order to strengthen the solids and invigorate the blood; for this disease is liable to return, especially if they have afterwards a fever of the putrid kind.

Of a PHRENZY.

A PHRENZY, if a primary disease, is a true inflammation of the dura and pia mater; if symptomatical, the inflammatory matter is translated into the meninges of the brain from some other part.

The primary phrenzy is preceded by heat and a violent

inflammatory pain within the head, a redness of the eyes and face, unquiet and troubled sleep, a slight degree of folly, watching, sadness, fierceness, sudden forgetfulness, a gathering of threads from the bedcloaths.

A symptomatic phrenzy succeeds any acute disease; but it is worst when it is preceded by an inflammation of the pleura, lungs, or diaphragm. A black tongue, an obstinate costiveness, suppression of urine, white feces, which is always a fatal sign, pale, discoloured, thin urine, a wildness in the looks and actions, with a red visage, a black cloud in the urine, and watching, are signs of an approaching inflammation in the head.

The symptomatic phrenzy sometimes appears in the state of malignant, eruptive, and spotted fevers, the small-pox, malignant catarrhal fevers, camp-fevers, particularly the Hungarian. It generally supervenes about the critical days, with a rigor, trembling of joints, tension of the præcordia, and coldness of the external parts with thin urine. The patient being weakened with the preceding disease and long watching, which debilitates the tone of the vessels of the membranes of the brain; whence the states are not to be resolved, and whence the patient is generally killed on the third day.

A phrenzy is to be distinguished from that slight alienation of mind which happens in acute fevers before the critical eruption. This goes off readily, nor is the urine thin and watery, nor is it attended with a rigor and a refrigeration of the external parts. It is also to be distinguished from a desipience and raving, from a great loss of strength and weakness of the brain after the declination of an acute fever; for this will go as the strength returns, either spontaneously, or with proper remedies.

Both kinds, when present, have the following symptoms:

A deprivation of the ideas of sensible things, as also of the faculties of the mind and affections; an unruly fierceness and wildness; an unquiet and often turbulent sleep, a respiration slow and great, the face often exceeding red, the aspect grim, the looks fierce, the eyes wild and protuberant, a dropping of the nose.

A phrenzy is generally fatal on the third, fourth, or seventh day; which last it seldom exceeds.

When it does, and is violent, it often ends in madness; which increasing gradually, the patient becomes raving mad.

The aliment ought to be slender, of farinaceous substances, as water gruel acidulated; the drink, barley-water, small-beer, or the decoction of tamarinds.

This disease, of all others, requires the speediest applications. Profuse hæmorrhages of the nose often resolve it; and copious bleeding, by opening the temporal arteries, is the most efficacious remedy.

The cure of this disease requires diligent attention to the following things:

Varices of the veins, or the bleeding piles, are beneficial.

A looseness is likewise good.

A pain in the breast and feet, or a violent cough supervening, often put an end to the disease; as also an hæmorrhage.

Therefore plentiful bleeding is necessary, through a large

large orifices; or open several veins at the same time, viz. the *jugular*, the *frontal*, and a vein in the foot.

Hoffman prefers the bleeding at the nose, procured by thrusting up a straw, a pen, or a skewer; or, as Pringle advises, apply six or seven leeches to the temples. The rest of the cure consists in blisters, and things common to other inflammatory fevers.

The cure of the symptomatic phrenzy, if the pulse will bear it, is by opening a vein; but if this cannot be done by reason of great lowness, it is to be attempted by leeches and blisters. It is usual to begin with blistering the head, but in military hospitals that is to be left to the last. The best internal medicines are nitre and camphor. Hoffman's proportion is six grains of nitre to one of camphor; small doses of which are to be often repeated.

The patient's drink should be sweet whey, or acidulated by turning the milk with citron or lemon juice, and sweetened with *syr. a meconio*. To every quart add a dram of purified nitre or sal prunella. Also emulsions are convenient, of the four cold seeds, with barley-water, to every quart of which add two scruples of nitre.

Antiphlogistic clysters are likewise proper; but if all these means fail, recourse must be had to cupping in the lower parts, to opiates, and mild blisters.

Of the PLEURISY.

THE pleurisy is most predominant between the spring and the summer.

It begins with chills and shivering, which are soon succeeded by heat, thirst, inquietude, and the other common symptoms of a fever.

After a few hours the patient is seized with a violent pricking pain in one of his sides, about the ribs; which sometimes extends itself towards the shoulder-blades, sometimes towards the back-bone, and sometimes towards the fore-parts of the breast; and this is attended with frequent coughing.

The matter which the patient spits at first is little and thin, and mixed with particles of blood; but as the disease advances, it is more plentiful and more concocted, but not without a mixture of the blood.

The fever keeps an equal pace with the cough, pain, and spitting of blood; and in proportion as the expectoration becomes more free, it sensibly decreases; sometimes the body is collic, sometimes too open.

The blood drawn from a vein, as soon as it is cold, looks like melted suet.

In this disease the pulse is remarkably hard, and seems to vibrate like a tense string of a musical instrument, which is the pathognomonic sign.

Hence pleuritis are distinguished into the moist and the dry. It is likewise observable, that the pain in the side is more intense at the time of inspiration, but more mild at the time of expiration.

There is no fever wherein the crises are more regular than in the pleurisy and peripneumony: for in young persons, and those of a full habit of body, bloody spittle generally appears on the fourth day, and on the seventh the disease terminates by a profuse sweat. But in the phlegmatic and more inactive, as also those in whom the disease

has taken deeper hold of the lungs, it will continue till the eleventh or fourteenth day; going off partly by expectoration, partly by sweat: then the pulse becomes more soft, and the patient falls into an easy refreshing sleep.

But when on critical days the crisis is imperfect, there is indeed a sweat; but it neither eases the patient, nor terminates the disease. When it continues till the twenty-first day, there is reason to fear a dangerous abscess in the breast. It is therefore a good sign when the expectoration proceeds from the bottom of the lungs, bringing up a viscid matter on the fourth day, mixed with blood, afterwards yellow, and sometimes purulent. The sooner the expectoration happens, the greater the hopes of recovery.

A looseness is not safe; urine without a sediment is a suspected sign; and a profuse sweat, unless on critical days, is still worse. On the eleventh and twelfth days a looseness is not much to be feared, unless too great, for it sometimes carries off purulent matter. If a bleeding at the nose happens about the fourth day, it is generally attended with a remarkable alteration of the disease.

Those who die of an inflammation of the lungs are suffocated, because the matter adhering to the vesicles and bronchial ducts cannot be coughed up.

In all inflammatory fevers, too hot a regimen is to be shunned, both with respect to the bedcloaths and the heat of the room; nor must the patient be exposed to the cold air nor drink things actually cold. Likewise all strong sudorifics, diuretics, and cathartics, are hurtful. Nor, if the patient has three or four stools, must the course of nature be stopped.

The DIET should be cooling, relaxing, slender, and diluting. Moistening things taken warm are preferable to all others. Hence, barley or oat meal gruel, sweetened with honey, is proper; as also sweet whey.

The indications of cure are, 1. To prevent the farther stasis and stagnation of the blood. 2. To dilute and dissolve the lentor of the blood in pleuritis. 3. To mollify, ease, and relax the spasm, pain, and copious afflux, in order to put the impacted blood again into motion by the help of the appulse of the arterial blood. 4. To promote the excretion of the viscid, bloody, and virulent matter, adhering to the bronchia of the lungs, so that it may be brought up and an abscess prevented.

Take away ten ounces of blood on the side of the part affected. If the physician is called before the third day, the patient lying on his back, must lose a large quantity of blood from a wide orifice in a large vessel, and fetch deep sighs, or cough, to promote its celerity; and the part affected should be rubbed gently at the same time. The bleeding should be continued till the pain remits, or the patient is ready to faint. It should be repeated as often as the symptoms return which it was intended to remove. The absence of the white inflammatory pellicle from the surface of the blood, when cold, shews it is time to leave it off. This Huxham confirms by his own experience; and adds, that after the fourth day bleeding is not safe. He likewise recommends fomenting the part; which often eases the pain, and terminates the disease. But if it is obdurate, he recommends slight scarifications; then cupping;

and afterwards a blister on the same place, which has been successful when the usual methods failed. An emollient cooling clyster should immediately succeed bleeding, especially if the body is costive; and nitrous medicines, with a cooling, emollient, diluting regimen, should be forthwith entered upon. Thin whey, a decoction of barley and red poppies, and emulsions, will serve for drink.

Though the symptoms should vanish on blistering, it will be more secure to bleed again; unless a profuse sweat comes on with relief from pain, and makes all other remedies unnecessary. But if the lungs are likewise inflamed, the cure cannot be so speedy; for though the first bleeding and a blister should give ease, yet a repetition will be needful. Sometimes the stitch returns and fixes on the other side; but this may be treated as the first with the same success.

Huxham lays a great stress on camphor and nitre joined with small doses of the pargoric elixir; and if there is a vehement pain, he thinks opiates may properly be joined with them, as they have a great power of relaxing the over tense fibres, of moderating the too rapid course of the blood, and of promoting the concoction of the morbid matter. Hence, after the use of opium, there is generally a copious sediment of the urine.

It is necessary that the body be kept open, and the bowels free from spasms; to which purposes emollient clysters are proper, with oil of sweet almonds.

In the first stage of the pleurisy or peripneumony, laxative clysters and the cooler diaphoretics are proper; but all cathartics and warm sudorifics do harm. The time for attempting the diaphoretics is when the person finds ease by the blister: But whenever the spitting begins, the diaphoretics must either be omitted, or joined to expectorants; whereof the chief is oxymel of squills; or, in great heat or drought, some more pleasant acid. But in lowness, after repeated bleedings, give salt of hartshorn joined to some oil: This will raise the pulse, and promote expectoration when it flags.

If, notwithstanding the discharge, the breast continues to labour, bleeding is still requisite: For the lungs are not to be overpowered by the omission of bleeding; nor is the suppression of the spitting to be hazarded by bleeding too freely. But with regard to blisters, there need little caution; as they are always seasonable, to raise, relieve the breast, and to promote expectoration.

In the course of expectoration, a vomit will sometimes be useful in discharging the load of viscid phlegm. If the phlegm is tough, or the patient costive, and opiates are given, they must be joined with squills.

When the pleurisy ends in a suppuration, or abscess, the signs are, a slight vague shivering, which often returns without any evident cause; a remission of the pain, while the difficulty of breathing remains; a redness of the cheeks and lips; thirst; a febricula, or slight fever, especially in the evening; a weak, soft pulse.

When the abscess is actually formed, there is an obstinate dry cough, which increases after feeding or motion; the breathing is difficult, small, thick, short, and wheezing, worse after eating and motion; the patient can only lie on the side affected; a slow, periodical fever,

which is exasperated with stirring and eating; a decayed appetite, great thirst, nocturnal sweats, paleness, leanness, and excessive weakness.

This either ends in a consumption; or the matter falls into the cavity of the thorax, and so becomes an empyema.

Of the BASTARD PLEURISY.

HOFFMAN says, that the seat of every genuine pleurisy is in the lungs, as appears from the opening of those that die of this disease.

Therefore, if the inflammation occupies the external parts only, it is a BASTARD PLEURISY: if the external surface of the lungs, like an erysipelas, it is a genuine pleurisy.

A BASTARD PLEURISY is attended with a very acute and pricking pain in the side, which is exasperated by the touch; lying on the affected side is difficult; there is a dry cough, without the ejection of purulent or bloody matter, which, if strong, increases the pain. There is likewise a fever, with a hardness, depressed, and frequent pulse.

The cause does not seem to be in the blood, but rather in the stasis of an acrid serum at the connection of the ends of the fine azygous arteries and veins; as also of the lymphatic vessels of the pleura, and likewise in the peritoneum of the ribs, where the sense is more acute.

Hence it is nothing else but a kind of rheumatism, and is common to those who are now and then troubled with catarrhs, rheumatic and arthritic pains, or a hemicrania; especially if they come out of a hot air into a cold, or the contrary, particularly in the evening.

This does not require bleeding, unless there is a remarkable plethora; but a diaphoresis, and a more free perspiration. On the seventh day it generally disappears, and is without danger.

Lanciscus advises to bleed plentifully in the arm, and to scarify the part affected. After this two cupping glasses are to be applied thereto, which will cure the disease as if by enchantment.

Hoffman observes, that those are apt to fall into a bastard pleurisy who are much exposed to a moist cold autumnal or wintery air: For there are no diseases or inflammatory fevers so soon generated by the intemperies, inequality, and change of the air, as those of the breast. When the summer has been hot and dry, and the weather has suddenly changed to cold, with a northerly wind, not only catarrhal defluxions have ensued, but rheumatisms and pleuritis, with bloody spittle and violent pains in the side, have been very frequent. For the air, from continual inspiration, immediately affects the lungs internally, and externally the thorax and ribs, which are beset with thin muscles, membranous nerves and vessels; for which reason spastic crispatures are readily induced, and the free circulation of the humours stop.

The best way is to keep the part affected in a temperate and equal heat, in a warm bed; especially as the skin of every patient, as in the gout and erysipelas, cannot bear topics.

Of a PERIPNEUMONY.

THERE are several kinds of this disease. For it may arise from a violent inflammation of the lungs, by a very sly dense blood obstructing very many of the pulmonic and bronchial arteries: or from an obstruction of the lungs by a heavy, viscid, pituitous matter; which is called a spurious or bastard peripneumony: or from a thin, acrid effluxion on the lungs; and then it is a catarrhal peripneumony.

The symptoms common to all, are, a load at the breast, a short difficult breathing, and more or less of a fever. But in a true peripneumony, there is a more tensive pain than in the pleurisy; besides, it is rather more obtuse and pressing than acute, and shoots as far as the back and scapulae. But the difficulty of breathing is greater, as well as the anxiety and expectoration, whereby a variegated spittle is brought up, which lay as it were deep: for in this disease the vessels of the lungs themselves, whereby the blood circulates from one ventricle of the heart to the other, are affected; being stuffed and obstructed with a thick blood, which is apt to grow more viscid and solid. Wherefore it is the more dangerous and fatal, especially if it attacks old persons, and if bleeding is not timely administered. Boerhaave says, the pulse is soft, slender, and in every sense unequal; and Huxham, that if the pulse is hardly felt before bleeding, it will afterwards beat very strongly.

In the cure, great regard must be had to the different stages of this disease, and the different symptoms that attending. Bleeding is indispensably necessary at the beginning of a severe inflammation of the lungs; but if, after the second or third bleeding, the patient begins to spit a well concocted matter, freely tinged with blood, you must forbear to repeat it, otherwise the patient will be weakened, and a fatal suppression of the expectoration will ensue. But if he brings up a considerable quantity of florid, thin, spumous blood, by spitting; then bleed again, quiet the cough with diacodium, and give proper acids pretty freely, with soft cooling inkrassants. If a thin, gleety, dark-coloured matter is expectorated, it is generally a mark of greater malignity, and that the blood is in a putrefying dissolving state, and will not bear a large loss of blood.

Generally the more violent the rigor or horror is at the attack, the more violent the succeeding fever will be, which will in some measure guide us in drawing off blood. If the symptoms are not relieved by the first bleeding, after eight, ten, or twelve hours, let it be repeated; or sooner, if they become aggravated. If the fever, anxiety, oppression, and difficulty of breathing, increase, bleed again, especially if it appears very firm and dense, or covered over with a thick yellowish coat or buff. However, it does not appear sometimes till the second or third bleeding, though the symptoms indicate a very high inflammation. This often happens from the blood not spouting in a full stream. This appearance of the blood, with a firm strong pulse, will warrant the taking away more, till the breathing becomes free and easy.

If the crassamentum is of a very loose texture, and not covered with a buff coat, and the pulse on bleeding sinks,

flutters, or grows more weak and small, it is time to desist. A bluish film on the blood, with a kind of a soft greenish jelly underneath, while the cruor itself is livid, loose and soft, with a turbid, reddish, or green serum, is a sign of a very lax crasis of the blood, and great acrimony, which will not bear great quantities to be drawn off. If the blood is very florid, thin and loose, with little or no serum after standing for some time, it generally argues a considerable advance to a putrid and very acid state.

A strong, throbbing, thick pulse, always indicates farther bleeding; at least till the patient breathes more easily, or a free expectoration of laudable matter is obtained. It often happens, that the pulse at the very beginning seems obscure and oppressed, irregular, sluggish, and sometimes intermitting, with weakness and oppression. But this does not arise from the defect, but from the too great quantity of blood; for the blood-vessels being over-loaded and distended, cannot act with sufficient vigour. This is succeeded with a dreadful train of symptoms, and even death itself, if not prevented with sufficient bleeding.

In some very violent peripneumonies, an immediate and excessive weakness comes on, with an inexpressible anxiety and oppression of the breast; a very small, weak, trembling pulse, coldness of the extremities, with clammy, coldish, partial sweats, the eyes staring, fixed and inflamed, the face bloated and almost livid. This has soon been followed with a stupor, delirium, and sometimes with a complete paraplegia.

Some kinds of peripneumonies will not bear large bleeding, especially the epidemic or malignant. The pulse and strength of these patients have sunk to a surprising degree; and the disease has turned into a sort of a nervous fever, with great tremors, subultus tendinum, profuse sweats, or an atrabilious diarrhoea, with a black tongue, coma, or delirium; though at the beginning the pulse seemed to be full and throbbing, and the pain, cough, and oppression so very urgent, as to indicate bleeding pretty strongly. In these cases the blood was seldom buffy to any considerable degree, but commonly very florid, of a very loose and soft consistence, or very dark-coloured, and coated with a thin and bluish or greenish film, under which was a soft greenish jelly, and a dark livid cruor at the bottom. Sometimes the coat was much thicker and more tough, but of a pale red colour, resembling the cornelian stone, or a dilute jelly of red currants. When the blood is thus dissolved, abtain from farther bleeding, especially if the pulse or patient becomes more languid after it, though the oppression, load, or even pain, may seem to require it.

When the sly coat on the blood is excessively tough, and extremely yellow, or of a pale red colour, it threatens danger; for the inflammatory lentor will scarcely mix with any diluents. Sometimes, after repeated bleeding, the crassamentum has scarce been a sixth part of the volume of the blood, and yet as solid as a piece of flesh. This is generally mortal.

When the peripneumonic symptoms continue for four or five days or more, we may justly fear an abscess, or a mortification; and little advantage is to be expected from farther

farther bleeding. But if the pain returns with violence after having ceased a considerable time, it is a sign that a new inflammation is forming, which indicates bleeding as much as the primary, but not in the same degree. The strength of the patient and pulse, the violence of the pain and difficulty of respiration, are, in a great measure, to determine the quantity. When the pulse and strength seem to require bleeding, cupping on the shoulders will relieve the breast and head. Likewise the use of blisters, issues, setons, are very serviceable in inflammations of the lungs.

Laying a blister on the part affected is the proper cure of a pleurisy; but a peripneumony is naturally more dangerous; and the more so as the epispastic cannot operate so directly on the lungs as the pleura. But even in this case, blistering is most to be relied on after bleeding. You may first blister the back, and afterwards one or both sides. Epispastics tend to relieve the breast, not only when applied to the chest, but also to the extremities; and promote expectoration: Whereas bleeding must be used cautiously, if at all, after the spitting appears.

The fever and the inflammation require a cool, diluting regimen, and nitrous and relaxing medicines; together with a moderately cool, free air, and quiet both of body and mind. A close room is very inconvenient; if it cannot be avoided, it should be prudently aired. There is nothing more proper than thin whey, a barley pisan with liquorice, figs, &c. the infusion of pectoral herbs, such as ground-ivy, maiden-hair, colt's-foot, hyssop, &c. These should be gently acidulated with juice of Seville oranges or lemons. Honey will render them more detergent. Any or all these things may be drank warm by turns in frequent small draughts, sipping them as it were perpetually. These relaxing, emollient drinks, and vapours arising from them, are in a more essential manner necessary, when the expectoration is very difficult and tough. When it is suddenly suppressed, and the difficulty of breathing greatly augmented, an emetic of oxymel of squills will be proper, if the violence of the fever is abated; but very little should be drank after it to promote vomiting.

When much sincere, florid, or frothy blood is spit up, take away as much blood immediately as the patient's strength will bear. If the hæmoptoe continues, bleeding in the saphœna will be found of the utmost service. Then direct cooling emulsions, nitrous, demulcent, and mucilaginous medicines; and vegetable and even mineral acids, if the spitting of blood is very considerable. The drink may be a decoction of red poppies, colt's-foot, and figs, acidulated with elixir of vitriol. The cough may be appeased with diacodium, or a soft linetus. But strong astringents and large doses of opiates are bad.

In a CATARRHAL PERIPNEUMONY, the matter expectorated is extremely thin and crude, and the defluxion very acrid as to excoriate the wind-pipe, causing an incessant and very violent cough. Here, a great loss of blood is not necessary; but some should be drawn in the beginning to abate the inflammatory disposition. Blisters should be applied early, and purgatives are proper to carry off the serous callosities. A demulcent, pectoral pisan is

proper to temperate the acrimony of the humours. It should be taken warm with mild diaphoretics. Coffee is a useful drink. Direct *diacodium*, or *elixir paregoricum*, to moderate the cough, in small doses often repeated: *sperma ceti*, *olibanum*, *myrrh*, and *camphor*, tend to incrassate the thin catarrhal humour, and abate the irritation.

In the PUTRID PERIPNEUMONY the expectoration is livid, gleety, and fœtid, frequently resembling the lees of red wine; sometimes more black, and sometimes very fetid. This is often the case of the highly scorbutic; particularly sailors, after a long voyage. Blood taken from these, appears to be in a dissolving putrescent state. The crassamentum is loose and tender, the serum turbid and reddish; the tongue is black; the teeth furred with a dark, thick sordes; the breath offensive; the urine high-coloured or blackish. Black spots, or a dysentery, frequently appear on the fifth, sixth, or seventh day. The pulse and strength sink after bleeding: sometimes a vast anxiety, fainting, a cold sweat, a thready intermitting pulse soon after. This has sometimes happened in in pleuro-peripneumonies, where the pain of the side was violent, the load at the breast great, and the cough considerable.

This will never bear a second bleeding to advantage; seldom the first, unless there is a considerable degree of firmness and tension in the pulse. When there is reason to be dissident, order scarifications and cupping.

In this disease give a decoction of figs, colt's foot, and red poppies, well acidulated first with juice of Seville oranges or lemons, and afterwards with *gas sulphuris*; or *elixir vitriol*, nitre, *olibanum*, *myrrh*, flowers of sulphur and bole may be administered, with *conserv. lulula*, rob of elder, currants, mucilage of quince-seeds, and *syrup. de rubeo idæo*: camphorated vinegar, with syrup of elder or rasberries, is an excellent medicine. A spoonful or two of these latter should be given ever and anon. Sound cyder, and wine and water with Seville orange or lemon juice, drank warm, promote expectoration when deficient. Tincture of roses with red poppy flowers, has moderated an inordinate defluxion of thin bloody ichor. However, oxymel of squills, and strong cinnamon-water, are frequently necessary to pump up the ichor, when a great rattling in the throat and difficulty of breathing indicate a vast quantity of it in the lungs. And yet the violence of the cough may be often appeased by elixir althematicum or diacodium. The patient is to be supported with sago, panada, hartshorn jelly, roasted apples, cream of barley, or thick gruel, with a little wine and juice of lemons, giving a little at a time, and often. Strawberries, raspberries, currants, cherries, may sometimes be indulged.

At the close, the whole depends on a well-regulated diet. A toast with diluted red port wine, mulled with Seville orange-peel, mace, or cinnamon, and well acidulated, may be very useful. Blisters are seldom beneficial in this case, but often mischievous.

A very thin yellow spitting, either shews that nothing but the thinnest part of the blood is strained through the arteries of the lungs, or that the whole mass of blood begins to dissolve; that its bilious principles are highly exalted, and that all tends to a general putrefaction. It is commonly

monly attended with a violent cough, and expectoration is performed with exceeding great difficulty. Many times it is succeeded by an hæmoptoe from the rupture of the vessels; particularly when the tongue appears very red, smooth, dry, and shining, with a kind of livid bladders at the top.

The concocted matter of inflammatory obstructions of the lungs is partly spit off, and partly carried off by thick turbid urine in large quantities, depositing much reddish or yellow-coloured sediment; and sometimes partly by bilious stools. Nothing promotes this urine, and these stools, more effectually than laxative clysters. Sometimes the morbid matter is critically translated to the legs, to the great relief of the breast; and therefore, in severe pulmonary disorders, a derivation of the humours to the legs may be attempted by tepid bathing and blisters. The discharge from the ulcerated blisters must not be suddenly suppressed; for then the difficulty of breathing and cough will return, or a very great purging or profuse sweats will succeed.

If the patient is not relieved in eight days, the inflammation will end in a suppuration, and an abscess of the lungs, and sometimes in some other part of the body; the symptoms of which are an obstinate dry cough, which motion and taking of food will increase. The easiest posture in lying will be on the affected side; there will be a slow fever, with chills and shivering at uncertain periods; exacerbations after motion or a repast; thirst; night sweats, a frothy urine, paleness, leanness, weakness. In this case, bleeding must be forborne; the diet must be mild, soft, inassating, and more plentiful. Tepid vapours should be taken into the lungs, of decoctions of proper ingredients.

When by the symptoms and time the imposthume may be judged to be ripe, the vapour of vinegar itself, and any thing which creates a cough, as oxymel, exercise, and concussion, are proper. The sooner it is broke, the less danger to the lungs.

In this state, which is not absolutely desperate, the aliment ought to be milk, and the drink milk and barley-water, with gentle anodynes, that the patient may have some rest. If the inflammation ends in a gangrene, the case is desperate; if in a schirrus, incurable.

Of the BASTARD PERIPNEUMONY.

At the beginning of the fever the patient is hot and cold by turns, is giddy upon the least motion, and complains of a rending pain of the head whenever he coughs; he vomits up every thing that he drinks; the urine is turbid, and intensely red; the cheeks and eyes look red and inflamed; his breathing is thick and short; the whole thorax is full of pain, and the straitsness of his lungs, as often as he coughs, is perceived by the by-standers; whence the free course of the blood is prevented, which creates a stoppage of the circulation, and takes away all the symptoms of a fever, especially in those of a full habit of body; this may also happen from the blood's being overloaded with a great quantity of pituitous matter, which oppresses it so as to prevent a febrile ebullition.

This disease sometimes steals upon the patient unawares, with a slight weariness, a weakness, a general prostration

of the faculties of the mind, thick and short breathing, beginning with an oppression of the breast. The commotions it excites are so small, that the heat and fever are scarce sufficient to make the patient sensible of his danger. Afterward, slight shiverings which come on by fits, and the attacks of a gentle fever, appear; whence the difficulty of breathing and weakness suddenly increasing, bring on death.

When perpetual, laborious wheezing, great anxiety and constant oppression on the præcordia, comatous symp- toms, cold extremities, and dark bad-coloured nails and visage come on, the patient is in immediate danger.

When comatous symptoms and a very difficult breathing remain after bleeding, cup and scarify the neck and shoulders. This has frequently had a surprising effect. When the case is very threatening, blister the scarifications.

After bleeding, let the patient have the following clyster, which must be repeated daily till the lungs are relieved,

Take 3 ounces of honey, the yolk of an egg, and 8 ounces of barley-water. Make them into a clyster.

Let the patient's diet be very slender, such as weak broths, sharpened a little with orange or lemon juice, and he may drink a weak mixture of honey and water; the steams of warm water may be taken in at the mouth.

Likewise let the legs and feet be bathed, and large blisters applied. Sydenham advises a repetition of the bleeding and purging alternately, every other day, or at greater intervals, as the strength and symptoms require. But he has generally found twice bleeding sufficient.

Of the INFLAMMATION of the LIVER.

When the liver is inflamed, it compresses the stomach, diaphragm, and the neighbouring viscera of the abdomen; it stops the circulation of the fluids, hinders the generation and excretion of the gall, and all digestion. It produces a great many bad symptoms, as the jaundice, with all the diseases depending thereon; for the liver receives the reflux blood from almost all the parts of the abdomen, and is the chief instrument of almost all the digestions that are made there.

A fever, an inflammation, and pungent pain on the region of the liver and diaphragm, a tension of the hypochondria, yellowness of the skin and eyes, and a saffron-coloured urine, are signs of an inflammatory disposition of the liver.

It begins with cold and shivering, sometimes with vomiting and a fever, watching, difficult breathing, inquietude, and coliciveness. This is a kind of rheumatic or erysipelatous fever, proceeding from a sharp viscid serum, lancing the nervous fibrillæ. It is sometimes accompanied with a bastard pleurisy, to which it is akin.

It is not very dangerous, and rarely kills, unless the viscera are unfound.

Narcotics and sudorifics are to be shunned.

This disease terminates as other inflammations, being cured by resolution, concoction, and excretion of the morbid matter; or else in an abscess, schirrus, or gangrene.

During the first state, a warm regimen and laudanum are improper.

Cooling resolving liquors, taken inwardly, as whey
† A a with

with sorrel boiled in it. Outward fomentations, and frequent injections of clysters, bathing, and frictions, relax, and render the matter fluid. Honey, with a little Rhenish wine, or vinegar; the juices and jellies of some ripe garden fruits; and those of some lactescent plants, as endive, dandelion, and lettuce, are resolvent.

Fat oily epithems, and plasters, are to be shunned. Camphor in croceated spirit of wine is only to be used in the beginning, or when the fever is moderate, and nature sluggish. Bleeding at first is necessary on the affected side, in the hand or foot.

Violent purging hurts; gently relaxing the belly relieves: diluents, with nitrous salts, are beneficial, or tamarinds boiled in warm water or whey.

A clyster purely oleous is beneficial, with a bladder-full of an emollient decoction. Inwardly, diluting and resolvent mixtures.

If it is attended with the jaundice, then apply epithems of *cardus benedictus*, scordium, wormwood, elder flowers, chamomile, seeds of lovage and cummin boiled in wine, and often applied.

Pringle says, the best remedy, after plentiful bleeding, is to lay a large blister over the part affected.

Bloody stools, not in an extreme degree, or streaked with blood, ought not to be stopped, because they help to resolve the distemper: bleeding at the nose often does the same.

The feverish matter is frequently carried off by urine; and therefore diuretics not highly stimulating are proper.

Sweating ought not to be promoted by hot cordials, but encouraged by warm diluting liquors.

The case is deplorable, when the inflammation terminates in a suppuration, unless the abscess points outwardly, so as it may be opened. For if the pus is evacuated into the abdomen, it produces putrefaction, or an incurable hepatic dysentery or bloody-flux.

Of a PARAPHRENITIS.

THIS disease is an inflammation of the diaphragm, and parts adjacent. A paraphrenitis is attended with a very acute continual fever, an intolerable inflammatory pain of the part affected; which is extremely augmented by inspiration, coughing, sneezing, repletion of the stomach, a nausea, vomiting, compression of the abdomen in going to stool or making water. Hence, the breathing is thick, short and suffocating, and performed only by the motion of the thorax. There is also a constant delirium; a drawing of the hypochondria inwards and upwards, an involuntary laughter, convulsions, and madness.

This disease terminates as in a pleurisy; but is attended with more violent symptoms, and is much more fatal. If the part affected suppurates, the matter will fall into the abdomen, and produce a purulent ascites.

The cure must likewise be attempted in the same manner as in a pleurisy.

Of the INFLAMMATION of the INTESTINES.

THIS disease contracts the intestines, and stops up the passage through them. There is a vehement, fixed, burning pain, which is irritated by things taken inwardly. When the inflammation is in the upper part of the inte-

stines, the stomach will be greatly distended by wind. When the pain is exasperated, it produces convulsions of the diaphragm and abdominal muscles, vomiting, painful inflations, with rumblings, and sharp gripping pains which may bring on the iliac passion, or twisting of the guts.

When there is a burning pain in the abdomen, with a preternatural heat of the whole body, as also a quick pulse, loss of strength, anxiety, and inquietude, the seat of the disease may justly be suspected to be in the intestines. If the sharp pain is above the navel and below the stomach, attended with a fever, nausea, and reaching, it is a sign that that part of the colon is affected which lies beneath the stomach, and is extended from the right to the left-side. If the pain lies in the right hypochondrium, under the spurious ribs, it shews that part of the colon to be inflamed where it joins to the ilium. When the complaint is of the left side, under the loins, where the psoas muscle is placed, it is a sign the colon and that part of the mesentery joined thereto is the seat of the disease, especially when it adheres to the peritonæum. But when the pain is in the middle of the abdomen about the navel, it shews the small-guts are certainly affected. In all these cases the pain is supposed to be attended with a fever.

When there is a fever, and a burning pain in the lower part of the belly, attended with a swelling, which ends in a copious, putrid, or purulent flux, with a great disorder of the bowels, it shews the seat of the disease to be in the mesentery.

This disease should carefully be distinguished from a cholic proceeding from a cold cause, because what is good for the latter is poison in the former. It must have a speedy remedy, or it will soon end in the iliac passion or a mortification.

Besides copious bleeding, there is hardly any other method of cure than fomenting and relaxing the bowels with emollient liquids, taken warm both by the mouth and in clysters, and this every hour. Yet acids in very desperate cases have been known to give relief; such as the juice of lemons taken by the mouth, and vinegar and warm water given in clysters. When the vomiting is excessive and continual, opiates should be given to quiet the convulsions.

Pringle affirms in this case, that the best method of cure is to lay blisters over the part affected; and it has been practised with success. In particular they are useful in the ileus, and seem to answer equally well in the fixed pains of the bowels, whether from an inflammatory or a flatulent cause.

Warm fomentations, or young, vigorous, and sound animals, applied to the body, are extremely beneficial. **ARBUTH.** The patient should only be nourished with broths, in which gently detergent roots have been boiled: **BOERRH.**

It is a fatal error of some practitioners, when they find the body obstinately colicive, to give one purge after another; which not only exasperates the disease, but renders it mortal. Even the clysters should not be made of very stimulating ingredients; but of milk alone, with a little nitre; or rain-water, with syrup of violets; or of marsh-mallows, or roses solutive.

After

After bleeding and clysters, if the pain still continues violent, there will be no manner of danger in giving opiates, by which means the excruciating pain will be alleviated, the spasms appeased, and a breathing sweat will follow. When this is done, and the fever is abated, there will be no occasion to continue the diluting, relaxing, and moistening medicines, but rather the nervous and corroborating.

If the patient survives three days, and the acuteness of the pain abates, with a chilliness or shivering throughout the body, it is a sign of a suppuration: then within fourteen days the imposthume will break; and if it falls into the cavity of the abdomen, it will corrupt the whole mass of fluids, putrefy the viscera, and turn to an ascites; whence the patient will die of a consumption.

In this case, whey and chalybeate waters are likely to prove most beneficial.

If the fever continues, with clammy sweats, paleness, an ichorous diarrhoea, fetid, black, or like the washings of flesh, a small intermitting pulse, and at last a total cessation of pain; they are signs of a gangrene and an approaching death.

Of the NEPHRITIS, or INFLAMMATION of the KIDNEYS.

THE symptoms of a nephritis are, a great inflammatory, pungent, burning pain, in the place where the kidneys are situated, attended with a fever; the urine is made often, but small in quantity, and very red or flame-coloured, yet, in the highest degree of the disease, watry. There is a numbness of the thigh, and a pain in the groin and the testicle, of the same side; a pain in the ilium, bilious vomiting, and continual eruptions.

When the inflammation is deep, the fever violent, the burning pain in the loins lasting, the difficulty of making urine great, the body very costive, the anxiety and straitness of the præcordia exquisite, the urine crude and white; likewise if the pain continues till the fourteenth day, the kidney will suppurate; which is known from the abating of the pain, and from the thick purulent sediment of the urine. This will sometimes last several years, till there is nothing left of the kidney but a bag: It is attended with a hectic fever, and the patient before he dies is almost reduced to a skeleton. If the bag happens to burst, it brings on a retention of urine, and intolerable pains, which end in death.

If it continues beyond the seventh day, an abscess is to be feared, which is known to be forming by a remission of the pain, succeeded by a pulsation in the part, and chilliness and shivering often returning.

When the disease is favourable, it is cured by resolution, of a copious, red, and thick urine discharged at one time, or by a large flux of blood from the hæmorrhoidal veins, in the beginning of the disease.

It is cured by plentiful bleeding, revulsion and dilution; by soft, emollient, antiphlogistic decoctions.

When a burning and fixed pain in the loins continues for some time, it is a sign that the renal vessels are stuffed and obstructed with a thick blood, which requires immediate bleeding in the foot; or if there is a disposition to a hæmorrhoidal flux, apply leeches to the anus.

Afterwards give such things as temperate the heat of the blood, and promote a free circulation, with a diaphoretic. For which purpose, emulsions, demulcents, diluents, antispasmodics, diaphoretic powders, with cinnabar and nitre, are preferable to every thing else.

Emollient clysters, without any saline or purging stimulus, are the principal help in this disease. They may be made of milk, whey, or soft water, in which elder and chamomile flowers have been boiled; to which add an ounce or two of syrup of marshmallows, and a dram of nitre.

When there are convulsions, or excessive pain, opiates are proper. If the vomiting, a symptom of this disease, is too frequent, warm water sweetened with honey is beneficial.

The patient should avoid all acrimonious aliment; he should neither lie too hot, nor on his back.

When an abscess is formed, the medicines must be powerfully maturing and emollient: When the urine appears purulent, they must be diuretics of medicated waters, whey, and the like; together with balsamics.

Emulsions are likewise useful of the four cold seeds and sweet almonds. Some attribute a great virtue to cherry-tree gum dissolved in whey or water, and taken often. Also syrup of marshmallows is very useful. Add to these, the decoction of veronica, sweetened with honey, and mixed with powder of nutmegs.

Butter-milk, not very sour, has been reckoned a great secret in ulcers of the kidneys; and chalybeate waters have been beneficial to some. Spruce-beer is a good balsamic in this case.

Of the INFLAMMATION of the BLADDER.

THE pathognomonic sort of this disease are, an acute, burning, pressing pain in the region of the pubes, attended with a fever, a continual tenesmus or desire of going to stool, and a perpetual striving to make water.

Other symptoms are, a rumbling of the bowels, gripping pains, great anxiety of the præcordia, difficult breathing, want of appetite, vomiting, coldness of the extreme parts, a hard, quick, unequal, contracted pulse, inquietude, and sometimes convulsions.

There is another kind which is more superficial, and is either rheumatic or erysipelatus, in which the fever is more easily and speedily cured by promoting a diaphoresis: And persons in years, or who are affected with the scurvy, gout, rheumatism, or violent head-achs, are most subject to it; especially if they catch cold by being exposed to the rigour of a cold north-wind.

The former arises most commonly from the stoppage of the menfes, bleeding piles, or other usual sanguinary evacuations; and not seldom from a violent gonorrhœa unskillfully suppressed by astringents, or when treated by medicines of too sharp and hot a nature.

This disease is mortal, if it terminates in an ulcer or mortification.

The cure must be attempted with bleeding in the feet, if a suppression of the menfes or hæmorrhoidal flux be the cause.

If it proceeds from the scurvy, &c. recourse must be had to gentle diaphoretics, diluents, and remedies which obdund.

obtund the acrimony of the humours, such as decoctions of the roots of scorzonera, china, skirrets, and fennel; also infusions, in the manner of tea, of the tops of yarrow, flowers of mallows, winter-cherries, and seed of daucus, made with milk, and sweetened with *syrup de althea*. If the patient's body is colicive, manna will be proper, with *nitrum sibiitum*; to which rhubarb may be joined, as occasion requires.

Externally, antispasmodics and gentle discutients will be proper: For this purpose apply bladders filled with a decoction of the emollient flowers.

If the tenesmus and difficulty of urine arise from spasms, there is nothing better than the vapours of a decoction in milk of the flowers of melilot, elder, chamomile and mallows, and the tops of yarrow. This decoction may be put into a close-stool; and the patient sit over it.

Tulpius informs us, that a desperate ulcer of the bladder was cured by the constant use of spaw-water.

Of the OPHTHALMIA, or INFLAMMATION of the EYES.

AN inflammation of the membranes which invest the eye is a very common disease, especially of the adnata or albuginous coat of the eye.

The eyes are very much inflamed, with great pain, tension, tumour, heat, and redness; and sometimes there is such a strong sensation of pricking in the eye, as if it was caused by a needle or thorn. The eyes at first are full of scalding tears; which are followed by a pituitous matter, which is sometimes small in quantity, sometimes more plentiful: a fordes adheres to the greater angle of the eye; and when the disease is violent, the neighbouring parts will swell even as far as the cheeks, with a strong pulsation of the adjacent arteries. The small blood-vessels are visible, which in health are not to be seen, and all the white of the eye becomes red.

If, besides these external signs, there is an appearance of moths, dust, flies, &c. floating in the air, there is an inflammation of the retina.

As in all diseases of the eyes, so especially in their inflammation, the patient must abstain from all spirituous liquors, the smoak of tobacco and sternutatories; he must likewise avoid smoaky rooms, and the vapours of onions and garlick, as also all vivid lights and glaring colours. The drink may be water alone, or a decoction of fennel-seeds, harthorn, and barley; the aliment must be light of digestion.

Intemperance of all kinds renders persons liable to this disease; as also a keen north-wind, and looking earnestly at the fire, sun, or glaring colours: likewise smoaky rooms, metallic vapours, costiveness, and unusual refrigerations of the extreme parts, especially in the time of menstruation. Sometimes it is owing to other diseases, as the small-pox, measles, scurvy, and the driving back the gouty matter.

A slight ophthalmia is easily cured; a more severe one generally continues a month or longer, and often leaves a spot in the cornea, or depraves the humours of the eye.

The slighter inflammations from dust or the sun are removed by fomenting with warm milk and water, and anointing the eyes with tutty ointment at night: if the eyes

are weak and but little inflamed, they may be washed with brandy and water.

In all cases we are to look narrowly and often into the inflamed eye; since the inflammation may be either begun or be kept up by moats, or by hairs of the cilia falling in, or growing inwards, so as to cause constant irritation.

Take away 10 ounces of blood, and the next morning give the common purging potion, which may be repeated twice or more, with the interposition of two days between each dose, and at night an ounce of diacodium.

On the days in which purging is omitted, let the patient take four ounces, three or four times in a day, of the emulsion of the four greater cold seeds, and white poppy seeds.

If the disease will not yield to repeated cathartics and bleeding, give an ounce of diacodium every night.

The slighter cases may be cured without bleeding; but if any degree of a fever is joined, or the inflammation is considerable, this evacuation is never to be omitted. The more violent inflammations are not to be cured without larger bleedings, unless we can make a derivation from the part affected without draining the whole body. For this purpose blisters are usefully applied behind the ears, especially if they are to lie on for two or three days, and if the sores are afterwards kept running. Two leeches should be applied to the lower part of the orbit, or near the external angle of the eye, and the wounds be allowed to ooze for some hours after they are fallen off.

This method will likewise do in ophthalmias from external injuries; but not when they proceed from a scrophulous or venereal cause. In bad cases, after the inflammation has yielded a little to evacuations, the coagulum aluminosum, spread on lint, and applied at bed-time, is the best external remedy.

In the mean while, blisters must be applied to the neck, and kept running for some days; and after that, setons, or issues at least. It is hard to say, of what vast advantage blisters and setons are in this disease.

The expressed juice of millepedes may also be given [25 are a dose] on the days purging is omitted; in four ounces of beer, or Rhenish or French white-wine: let them stand, when mixt, all night; and then take it with a little sugar in the morning, after the mixture is drained.

But according to the later experience of Dr Fordyce, Fothergill, and others, a strumous ophthalmia may be certainly and safely cured by half a dram of the bark given twice a day.

The length of time in which the bark is to be taken is uncertain, for in some the cure is performed in less time than others.

Hoffman, besides blisters, setons, &c. recommends cupping, with scarification, in the nape of the neck, and behind the ears; and in the violent sort of this disease, bleeding in the jugular; as also sinapisms of rocket-seeds boiled in wine, and then put into small bags and applied to the nape of the neck or under the armpits. For inward use, he prefers to all other remedies, an infusion, in the manner of tea, of valerian-root, liquorice, elder-flowers and fennel-seeds, drank plentifully; and before
the

the drinking of it to receive the vapour or steam into the eyes.

Of the APOPLEXY.

THIS disease is a sudden abolition of all the senses, external and internal, and of all voluntary motion, commonly attended with a strong pulse, laborious breathing, a deep sleep, and snoring.

There is no difference between a person asleep and in an apoplexy, but that the one can be awaked, and the other cannot.

The causes of this disease are a particular conformation of the body, as a short neck, for some have fewer vertebrae in their necks than others; a gross, plethoric, fat, phlegmatic constitution; polypous concretions in the carotid and vertebral arteries, or about the heart, or within the skull, which are known by an unequal pulse, a vertigo, and sometimes a momentary loss of sight; an inflammatory thickens of the blood, preceded by a fever attended by the head ach, redness of the face and eyes, an advanced age, attended with a glutinous, cold, catarrhus, leucophlegmatic constitution.

The forerunners of an apoplexy in these last, are, dullness, inactivity, drowsiness, sleepiness, slowness of speech and in giving answers, vertigoes, tremblings, oppressions in sleep, night mares; weak, watery, and turbid eyes; pituitous vomiting, and laborious breathing on the least motion.

Other causes may be, whatever compresses the vessels of the brain; as, a plethora, a cacochymy, attended with fulness of the vessels; a hot constitution; tumors within the skull; the velocity of the blood increased towards the head, and diminished downwards; compression of the veins without the skull, which bring the blood back from the brain; the effusion of any fluid compressing the dura and pia mater externally; the effusion of any fluid within the brain, which by its pressure hurts the origin of the nerves; this is the most common cause of apoplexies, and proceeds from blood in the plethoric, from a sharp serum in the hydropical and leucophlegmatical, and from an atrabilious acrimony in the melancholic, the scorbutic, and the podagric. Violent passions of the mind, and intense study, are prejudicial to these.

There are three degrees of an apoplexy. The first is, when the vital fluids are, by the force of violent distensions, driven from the lower and outward parts of the body, to the external parts of the head, and to the brain and its meninges, by the carotid arteries; whereby their vessels are expanded, and the free circulation through them impeded. While this stagnation of the blood continues, the external and internal senses are abolished; and as the stoppage goes off they are gradually restored. Such are the fits that hypochondriacal and hysterical persons are subject to.

The second degree is, when the stagnation continues so long that the serum oozes through the vessels, and falls upon the sides of the medulla oblongata or spinalis, and so stops the influx of the nervous fluid, and produces a hemiplexia or a palsy.

The highest degree is, when the fine vessels of the pia

mater are broke, and the extravasated blood occupies the basis of the brain.

The first may be cured by timely bleeding: the second, though it does not suddenly kill, yet it generally renders the patient infirm ever after: the third is almost always mortal.

The immediate forerunners of an apoplexy, are trembling, staggering, a giddiness in the head, a vertigo, dimness of sight, a stupor, sleepiness, forgetfulness, noise in the ears, more deep and laborious breathing, the night-mare.

A slight apoplexy goes off in a profuse, equal, roscid, warm sweat; a large quantity of thick urine, by the bleeding piles, the flowing of the menses, a diarrhoea, or a fever. If it is more severe, it usually terminates in a paralytic disorder; and is seldom curable, but always leaves behind it a great defect of memory, judgment, and motion.

Bleed in the arm to 12 ounces, and then in the jugular to 7 ounces; immediately after which, give an ounce and a half, or two ounces, of emetic wine.

Apply a large strong blister to the neck, hold the patient upright in bed, and let the spirit of sal ammoniac, highly rectified, be held to his nose.

Let there be strong frictions of the head, feet, and hands: and let the patient be carried upright backwards and forwards about the room, by two strong men. Strong blisters should be applied to the head, neck, back, and calves of the legs. Sharp clysters should be thrown up into the body, which have a tendency to excite the patient, and to cause a revulsion.

Shaw advises, during the fit, to bleed largely in the arm, or rather in the jugular, to apply strong volatiles to the nose, to blow sneezing powders up the nose, as also to rub the temples with spirituous cephalic mixtures.

Likewise to blow in the mouth and nostrils the smoke of tobacco from an inverted pipe.

Those who have once had a fit of the apoplexy, are very liable to be seized with it again; and if they are plethoric, the best preservative is bleeding once in three months, and using themselves to a spare diet; taking medicines which strengthen gently, and abstaining from cares and all intense applications of the mind; not neglecting issues and setons, nor the drinking suitable mineral waters.

Of the Palsy.

A Palsy is a lax immobility of any muscle, not to be overcome by the will of the patient. Sometimes the sensation of the part is absolutely abolished, and sometimes there remains a dull sense of feeling, with a kind of tingling therein.

It may be caused by all things that bring on an apoplexy; that render the nerves unfit to transmit the animal spirits; that hinder the entrance of the arterial blood into the muscle. Hence the nature of a paraplegia or hemiplegia, and the palsy of a particular part, may be understood.

Hence a palsy may proceed from an apoplexy, an epilepsy, extreme and lasting pains, suppressions of the usual

evacuations, translations of the morbid matter in acute distempers; whatever distends, distorts, compresses or contracts the nerves, strong ligatures, luxations, fractures, wounds, gangrenes, inflammatory and other tumors of the coats of the nerves, in the ganglia, or the nerves themselves; extreme heat, violent cold, mineral effluvia, and the too frequent use of hot water.

Palsies of the heart, lungs, and muscles serving for respiration, are soon fatal; of the stomach, bowels and bladder, from internal causes, very dangerous; of the face is bad, and easily changes to an apoplexy.

If the part is cold, insensible, and wastes away, it seldom admits a cure; if attended with a violent convulsion and great heat of the opposite part, it is very bad.

The regimen in this disease ought to be warm and attenuating, consisting of spicy and cephalic vegetables, such as create a feverish heat, because it is necessary to dispel the viscosity. Soapy vegetables are best, and such as consist of an acrid volatile salt, and oil, mustard, horse radish, &c. stimulating by vomits; sneezing; relaxing the belly; promoting sweat by such motions as can be used, or other means; by strong friction, &c.

The cure of the palsy is to be attempted by attenuants and discutients; such as, aromatic, cephalic, nervous and uterine vegetables; their fixed and volatile salts; as also by their oils; soaps made of their oils and salts; the strong scented parts of animals; the juices, spirits, oils, and tinctures of insects; fossil salts, metallic crystals, and medicines compounded of these.

Likewise by things which stimulate strongly, and which, by exciting a tremulous and convulsive motion of the nerves, drive out the impacted matter; to this class, sternutatories and emetics chiefly belong, especially if often used at first.

By purging with warm, opening, aromatic vegetables, with acrid fossils, with mercurial and antimonial preparations, in a large dose, and repeated successively for several days, by the means of which a copious and lasting diarrhoea may be excited.

By filling the vessels of the body with drinking a large quantity of the attenuants above mentioned, and then by exciting a greater motion and sweat by the vapours of spirits set on fire.

Outwardly, frictions may be used, either dry and hot, till the part is red; or with spirits endued with a stimulating virtue; or with nervous oils, liniments, balsams, or ointments; vapour or immerfive baths; acrid, aromatic, and drawing plasters; cupping, scarifications, blisters; whipping the part with rods; exciting a slight inflammation with nettles, and the like.

A course of electrification for some weeks has been known to have cured some inveterate palsies, though it hath failed in others. See ELECTRICITY.

Of the Epilepsy, or Falling-Sickness.

SOMETIMES this disease comes on suddenly and unawares; but it often gives notice of its accession by some preceding symptoms; the chief of which are, a lassitude of the whole body, a heavy pain of the head with some disturbance of the senses, unquiet sleep, unusual dread, dimness of sight, a noise in the ears: in some there is a

violent palpitation of the heart, a puffing or inflammation of the precordia, a stopping of respiration, a murmuring noise in the belly, fixed stools, a flux of urine, a refrigeration of the joints: in others, there is a sense, as it were, of a cold air ascending from the extreme parts to the heart and brain.

Then they fall suddenly on the ground, (whence the name of the falling sickness;) the thumbs are shut up close in the palms of the hands, and are with difficulty taken out; the eyes are distorted or inverted, so as nothing but the whites appear; all sensation is suspended, inasmuch that by no smell, no noise, nor even by pinching the body, can they be brought to themselves; they froth at the mouth with a hissing kind of a noise, the tongue is lacerated by the teeth, and there is a shaking or trembling of the joints.

However, the convulsions vary, as well as the defect of the senses, both in degree and kind; for sometimes, instead of convulsive motions, the limbs are all stiff, and the patient is as immovable as a statue. In infants the penis is erected: in young men there is an emission of semen, and the urine very often streams out to a great distance.

At length there is a remission of the symptoms, and the patients come to themselves after a longer or shorter interval; then they complain of a pain, torpor and heaviness of the head, and a lassitude of all their joints.

These fits are more frequent or seldom, or longer or shorter; according to their different causes. Some return on certain days or hours, or even months, according to the quadratures of the moon, but especially about the new or full moon; in women, chiefly about the time of menstruation: and what is most remarkable, often upon a very slight occasion; for instance, any sudden perturbation of the mind, as a fright, anger, sudden joy, intense application, strong liquors, excessive heat or cold, or venereal exercises.

As to the prognostics; in boys, this disease terminates about the seventh, the fourteenth, or the seventeenth year, that is, about the time of puberty; in women, about the fourteenth, viz. the time of menstruation. Likewise it has been found by experience, that chronical epilepsies have spontaneously ceased by the change of place, diet, and way of life. Sometimes a quartan ague will put an end to an epilepsy and convulsion-fits. It is also remarkable, that the itch, or any other cutaneous distemper, such as the small pox, measles, miliary eruptions, &c. will either abate the violence, or quite stifle this disease.

The patient therefore need not despair of a cure, if the disease is not of long standing, the fits short, the disorder not hereditary, and the years advancing to the time of puberty; or if it proceeds from a fault in the *prima via*, from worms, from a bad regimen, or from a subcutaneous disease ill cured. Nor is the case desperate if the epilepsy be slight, and when the fit is foreseen by a sensation of cold air, arising from the extreme parts to the back, præcordia, and head, and also when it is ushered in by anxiety, by want of strength, and a propensity to vomit; or when the senses are not quite abolished in the time of the fit, or when it comes on in the night, without the incurvation of the thumbs,

It is a bad sign if the epilepsy makes its first attack after the twenty first year, but much worse if the fits grow more frequent; for then the animal functions are often destroyed, and not only the memory, wit, and judgment are impaired, but the patient grows stupid and foolish. It sometimes ends in melancholy or madness. When it turns to a palsy or apoplexy, it is mortal.

The epilepsy is extremely difficult to be cured in adults, but in children it is the reverse. Blisters laid to the back part of the head are of great use a little before the paroxysm is expected: and the time may more certainly be foreknown, as this disease is influenced by the moon, and attends upon its phases. especially the new or full moon. The most proper medicines to correct the juices seem to be native cinnabar, and wild valerian root; a dram of which may be given morning and evening for three or four months, and afterwards two or three days before the new and full.

However, it must not be forgot, that this disease owes its origin to so many different causes, and is bred in so many different constitutions of the body, and the same remedy which succeeds in one case often fails in another; and therefore different medicines are to be tried, especially on adults. And great regard must be had to the times in which the paroxysms usually return, in order to effect a cure.

If the vessels are full of blood, or it is carried with too great an impetuosity towards the head, then bleeding in the ankles will be proper, or leeches applied to the hæmorrhoidal veins. This often happens to hypochondriacal or hysterical persons, to the melancholic, and women with jaundice. Sometimes it will be proper to bleed in the jugulars; or to apply cupping glasses with scarifications to the neck, and parts near the head.

It has its origin from a sharp, impure serum in the head, or in the membranes and vessels, as in cachectical or scorbutical persons, or those who have been inconsiderately cured of oedematous swellings of the feet, old ulcers, or issues dried up; the driving in of the itch, scabs, or the ulcerating humour of a scald head; then the cure may be attempted by cathartics, by purifiers of the blood, by evacuating the impure humours with setons, issues, cauteris, and blisters.

If it proceeds from violent pain, as for instance, from a stone striking in the ureter, from the tooth-ach, ear-ach, or spasms of the stomach and bowels; then clysters of oil of sweet almonds, or the like, are to be administered.

If, in children, it proceeds from gripes. or the breeding of teeth, nothing is better than to cleanse the *primæ viæ* from filth, by milk-clysters, with a little Venice soap dissolved in them.

If from worms, after antiseptics and soft oily things, anthelmintics must be given, such as tansey, garlick, camphor, asa fetida, worm-feed, mercurius dulcis, and ethiops mineral, or powder of tin.

When the fits return at certain periods, or at the quadrants of the moon, a clyster or a vomit will be proper first of all, of half a dram of ipecuanha, in a decoction of raisins.

In the time of the fits, too free a use of volatiles,

spiritous liquors, and strong smells, are hurtful, as causing the humours to flow too much to the head: The best method is to place the patient in an erect posture, and to rub the hands and feet pretty briskly.

The belt drink is water, which will mitigate, if not cure the symptoms.

When the patient is so happy as to foresee the accession of the fit, then let him have immediate recourse to clysters and frictions of the lower parts.

A milk-diet alone has cured an inveterate epilepsy. Mistleto is said to cure an epilepsy as sure as the bark an intermitting fever. The dose to grown persons is half a dram or more, in powder; every sixth hour, drinking after it a draught of a strong infusion of the same plant. If to every ounce of the powder, a dram of asa fetida be added, the medicine will be still more effectual.

Cinnabar of antimony is greatly celebrated for the cure of this disease; and may be taken from four grains to a scruple, in conserve of rosemary flowers.

Ferreus and Jachinus affirm, they have cured many epilepsies with a simple decoction of guaiacum, giving six or eight ounces of it twice a-day, and the secondary decoction of the same for their ordinary drink. This decoction should be continued 30 or 40 days, to which may be added male piony root, or something of the same kind; and every dose may have a few drops of the spirit of vitriol added thereto.

After all, there is no medicine that can be depended more upon than MUX; for it is an excellent remedy in all diseases of the nerves, particularly cramps, convulsions, vertigoes, and epilepsies. Ten grains may be taken morning and night, made up into a bolus; if the same quantity of scititious cinnabar be added to each dose, it will not be the worse.

Of St VITUS'S DANCE, and other convulsive disorders,

St Vitus's dance is a sort of a convulsion, which boys and girls are sometimes subject to, from the age of ten years, to the time of puberty. It discovers itself first by a kind of lameness, or an inability of one of the legs, which they draw after them in a ridiculous manner, nor can they hold the arm of the same side still for a moment; for if they lay it on their breast, or any other part of their body, it is presently forced away from thence by a convulsive motion. If they are desirous of drinking, before they can bring the cup to their mouth, they use a thousand odd gesticulations like a mountebank; for they cannot bring their hand in a direct line to their mouth, but it is forced this way and that, till at length, if they have the good fortune to hit the mark, they throw the liquor down their throat as greedily as if they designed to raise laughter in the spectators.

In a convulsive paroxysm, the limbs are strangely agitated with various different postures and motions. Sometimes the hands are put behind them as if they designed to sit upon them, and soon after they seem to be beating the air; then their legs will be drawn hither and thither as if they were dancing some antic dance. Sometimes they will bend their backs like a bow, at the same time raising their breast as high as they can; then their whole body will grow stiff, and as immoveable as a stone. They

generally

generally keep on their legs without falling; yet some will grovel on the earth like epileptic persons, and will weep, laugh, gnash their teeth, gape with their mouths, put out their tongues, roll their eyes, and whirl their heads about in a strange manner.

After the fit, some are inexplicably weak; some faint away, others fall into a deep sleep; in others, again, the fit is terminated with eructations, wind, vomiting, and throwing out plenty of water. Very often a mucus distils from the nose, or blood issues from thence, or from the uterus or hæmorrhoidal veins.

These persons have generally unquiet sleep, and full of dread and terror, an uncertain appetite, their bodies generally a little collicive; they sweat with difficulty, but are subject to great passions of the mind. The accessions of the fits keep exact pace with the phases of the moon. In women they precede or accompany the eruption of the menfes. They are most frequent and worst after meals; and are easily excited by the passions of the mind.

The fits are generally preceded with a coldness of the feet and limbs, or a kind of tingling sensation; which also affects the os coccygis, and like cold air ascends up the spinal marrow; there is a distended flatulent pain in the left hypochondrium, and such a constipation of the body that neither wind nor excrements can make their exit, nor will the anus admit a clyster-pipe, or, if it does, the clyster and excrements are thrown up by vomit. The bladder is likewise so affected, that no urine can be made, or at least but little, and thin and white. In others, the accession begins with yawning, stretching, anxiety about the heart; a hard unequal contracted pulse, the heart-burn, nausea, vomiting, palpitations of the heart, difficulty of swallowing, pain of the head and teeth, noise in the ears, giddiness, &c. and then come on the convulsions.

Though this is a terrible disease, it never kills suddenly. When it is recent, the person young, and otherwise of a good constitution, there is the greatest hopes of a speedy cure. If usual evacuations of blood by the uterus or hæmorrhoids are suppressed, the return will either mitigate or cure the disease. On the contrary, if the humours are thick and impure, the suppression obdurate, their temperament inclining to great sensibility, the age advanced, or the disease hereditary, or become habitual, the cure is difficult. Sometimes, through ill management, it degenerates into an epilepsy or hypochondriac melancholy.

To cure the St. Vitus's dance, take away about 8 ounces of blood, more or less, according to the age of the patient; the next day give half, or something more of the common purging potion according to the age, and in the evening the following draught:

Take an ounce and a half of alexeterial water; 30 drops of compound spirit of lavender; a couple of theriacal andromachi; and 8 drops of the tinctura thebaica. Mix and make them into a draught.

Let the cathartic potion be repeated thrice every other day, and the same draught in the evening. After which, bleed again, and repeat the cathartics three or four times; and this course may be pursued to the third or fourth time.

Apply to the soles of the feet *emplastrum o caranna*.

For fear of a relapse, at the same season of the next year, or a little sooner, in which the distemper appeared, bleeding should be again repeated, and purging two or three times.

Allen cured two girls of this distemper with the expulsion of millipedes and the Peruvian bark, after bleeding and a gentle cathartic.

As to the cure of other convulsive disorders, if the patient is plethoric, or the pulse great, it must be begun with bleeding either in the arm or foot; and if occasion require, it must be repeated two or three times, but not till the fit is over. The air should be dry and serene, with constant exercise; the aliment should be easy of digestion, and all hot spirituous liquors should be avoided. The constant drink should be the decoction of scorzonera roots, with shavings of hartshorn, or whey, or the Selter's mineral waters. *Pediluvia* are likewise proper, of river water, wheat-bran, and chamomile-flowers. They should be used pretty warm and deep, at the time of going to bed, and afterwards sweating should be promoted.

The patient's body, if collicive, must be kept open with manna, or with oily clysters; and if the *femes* of the disease is judged to be in the *prime via*, it will be proper, at the changes of the moon, to give a vomit with manna, that is, an ounce of manna with two or three grains of tartar emetic.

If, about the time of puberty, this disease proceeds from too early or excessive coition, or violent passions of the mind, all things which cause a commotion in the fluids must be avoided; such as, aromatics, sharp purges, emetics, spirituous liquors, inordinate motions of the body or mind, and all heating things in general. On the contrary, the diet should be soft, emollient, and nourishing; such as cow's or ass's milk, or whey; as also baths of sweet water mixed with milk. Likewise jellies, and decoctions of scorzonera, barley, hartshorn, ivory shavings, and viper's flesh, for ordinary drink, and chocolate.

If it proceeds from worms, the cure depends on their being killed and expelled out of the body: But all anthelmintics, or worm medicines, are not to be made use of in this case; such as garlic, vitriol, copper, aloes, sharp purges, and mercurials; because, if they are given inconsiderately, they are hurtful to the nerves. It will be better to use clysters, made of milk, sweet things, and oil; as also liniments of a purging quality applied to the navel and abdomen. Inwardly may be taken *semen fantanici*. If *mercurius dulcis* is given with a cathartic, it will be necessary first of all to let the patient take a few spoonfuls of oil of sweet almonds.

If it is caused by a suppression of the menfes, emmenagogues and hot medicines are to be forborne; but bath-waters and bleeding will be proper; as also *pediluvia*, if made pretty warm; hot infusions of balm flowers, and flowers of the lime-tree, tincture of castor, absorbent powders, antispasmodics, and anodynes.

If from a stoppage of the hæmorrhoidal flux, besides bleeding and the above remedies, leeches applied to the anus will be of very great advantage.

In the observations of the medical society of London, we have an account of a deplorable convulsive case being cured by electricity.

Of the CONVULSIVE ASTHMA.

As asthma is an impeded and very laborious respiration, attended with unspeakable anxiety, and a straitness about the præcordia, hindering the free circulation of the blood through the lungs, arising from variety of causes, and not without danger of suffocation.

There are several sorts of asthmas. One is, difficulty of breathing, proceeding from corpulency and a very full habit of body; and is most apparent after violent motion: but this is a slight disorder, and free from all danger. The next is the pituitous asthma, attended with a moist cough, and the bringing up pituitous matter; it attacks the patient at all hours, and in all positions of the body, and is owing to a plenty of a viscid mucus, stuffing the vesiculæ of the lungs, and hindering the free ingress and egress of the air through them. Another is owing to the convulsive contraction of the parts designed for respiration, and proceeds from various causes both within and without the thorax; and this is called the dry flatulent or convulsive asthma.

There is a heaviness of the breast, a slowness to perform customary labours, difficult breathing when going up a hill; the patients grow hoarse, cough, and are troubled with frequent eructations; they cannot sleep, and are scarcely warm in their beds. As the disease grows worse, the cheeks look red, the eyes grow prominent as if they were strangled; they snore or wheeze while waking, but much more when asleep; they are fond of cold air, they keep themselves in an erect posture, and seem to suck in the air with open mouth: they are troubled with sweating about the neck and forehead; then comes on a violent cough, and the patient brings up a little cold frothy matter. As they draw in their breath, the neck swells, and the præcordia are pulled upwards; the pulse is small and quick. If it increases, the patient is in danger of suffocation: but if it grows better, the fits are seldom, and greater plenty of matter is coughed up: the urine is more plentiful, but without a sediment; the voice grows clearer, the sleeps longer than are necessary, the præcordia are set at liberty; a pain sometimes passes to the shoulders: the breathing is slow and gentle, but with a sort of a wheezing.

The longer this disease continues, the more sharp and violent all the symptoms become. The patient's body grows more costive, and the urine is thin and watry; most commonly the feet swell, then the hands, face and back; there is a numbness of the arms, the countenance is wan and livid, or of a leaden colour. Then comes on a little fever, which grows worse in the evening; the whole body is cachectic, with an œdematous swelling of the feet; there is a dropy of the breast, or an ascites, or anasarca; at least there is a palsy on one side, or of the arm; or, instead, thereof a palsy of the eyelids.

When the disease is recent, and is owing only to the spasmodic contraction of the præcordia, there are hopes of a cure; especially if the matter of the gout, ulcers, and exanthemata, are sent back to their proper seats. When the menfes or hæmorrhoids which were stopped return, it yields relief, and, if the disease was not too far advanced, perfect health. If it is inveterate, or ill man-

naged, it brings on a dropy of the breast, obstructions of the lower belly, œdematous swellings of the feet, a cachexy, and an universal dropy. In general, all convulsive asthmas portend a sudden exit, or suffocation, especially if there is a polyypus of the heart: if it continues long, then the patient will die of the dropy; in which case it will be soon fatal; when there is a slow fever, an unequal intermitting pulse, a palsy of the arms, a continual palpitation of the heart, little urine, a syncope or swooning, then death is at hand. Some are carried off by an inflammation of the lungs, and the more grievous the disease the more languid the pulse. The asthma, in old persons, continues till death.

In the paroxysm, because the body is generally bound, and the wind and humours are carried upwards, the speediest assistance is from emollient and carminative clysters.

Afterwards use frictions of the feet, which have an incredible efficacy; also let them be put into warm water; for the feet are almost always cold. When there is a violent spasm about the præcordia, hot fomentations are necessary, or bladders filled with hot milk, and applied to the part affected; likewise nervous liniments are very useful, rubbed in with a warm hand.

Internally, antispasmodics should be given, with gentle diaphoretics.

And this is all that needs to be administered in the fit. Out of the fit, if it proceeds from too great a congestion of blood about the breast, or from a polyypus of the heart, bleeding in the foot will be proper, as also scarifications; in a suppression of the hæmorrhoids, leeches should be applied to the anus; also gentle laxatives to cleanse the *primæ viæ*; likewise bodily motion, slender diet, and soft drink. If there are hypochondriacal or flatulent symptoms, then gentle laxatives will be the more necessary, together with clysters. When the menfes or hæmorrhoids are suppressed, nothing is better than the bath-waters, both for bathing and drinking; or the waters of Selters taken warm and mixed with milk.

When the asthma proceeds from the driving back some impure matter from the skin, or from the drying up of ulcers, and the humour is translated to the nervous parts of the breast, then gentle diaphoretics will be necessary to send it back to the superficies of the body.

After which the patient may drink tea made of balm, or elder, or lime tree flowers, with the leaves of scordium, or veronica and fennel seeds, or any thing else of the same kind. Remedies compounded of sulphur are likewise very efficacious in driving back the morbid matter to the skin, though outwardly they are hurtful in cutaneous diseases.

The returns of the fits are to be observed and guarded against, by moderate evacuations, as bleeding gently vomits, laxatives, and sometimes cathartics: but every thing that heats the blood should be carefully avoided, especially about the usual times of the paroxysms; because there is generally then a lurking fever which ought not to be exasperated by heating food or medicines.

In a dry asthma proceeding from fumes of lead, an air replete with exhalations from quick lime, or the vapours of pitcoal; milk, cream, oil of sweet almonds, emulsions

of sperma ceti, the fat of animals used internally and externally, answer every purpose.

Country air, and following the plough, are beneficial to restore the debilitated tone of the lungs; and tea, made with hyssop, veronica, ground ivy, liquorice, and dairy flowers. cannot be enough commended. But sweet things, in every kind of asthma, are hurtful, especially in the humid or serous, and the hypochondriacal.

Of a Cough.

THE cough now under consideration is a primary disease, which greatly disorders the whole body by its vehemence and obstinacy. Its cause is, a flux of serous humours from the outward parts and extremities of the body to the lungs, and is seldom without feverish heats and shiverings towards the evening.

It is either moist or dry: the former afflicts the phlegmatic, whose fibres are lax and muscles soft, and who abound with serous and pituitous humours. Women are more liable to it than men; as also infants, boys, and old men, more than those in the vigour of their age. The dry cough principally attacks the hypochondriac, the scorbutic, the cachectic, and those who are lean and slender, and subject to convulsive disorders, and whose bodies likewise abound with a sharp serum.

The most violent of these kind of coughs is the *tussis convulsiva*, or *serina*, whose effects are so violent as almost to put the patient in danger of suffocation: In children, this is called the whooping cough. Sometimes this is dry in the beginning; or the patient brings up a little thin serum, more or less sharp. Sometimes it is moist; and then after a very laborious fit, the patient expectorates a sublivid, and commonly a moist tough mucus. The extreme parts grow cold, the body is collic, the urine and the vital fluids are driven in greater plenty and force towards the breast and head; so that while the proxyfym lasts, the face is red and turgid with blood, the veins swell, the arteries beat quicker and stronger, the eyes are ready to start out of the head, the tears flow, the eyelids swell, and sometimes the blood, after sneezing, springs from the nose. Sometimes the very vessels of the lungs burst, and a spitting of blood ensues. Sometimes a hiccup supervenes, and then at the same time the patient is affected with laborious vomiting; some discharge their excrements and urine insensibly; and the coughing of others is so violent as to cause ruptures, especially in children.

As to the prognostics, a dry cough often turns to a moist, by hurting the digestion, and rendering the patient cachectic. When a moist cough becomes suddenly dry, and the breast remains oppressed, we may conclude that a putrid or hectic fever, or an exulceration of the lungs are near at hand. In the convulsive cough of children there is danger of a suffocation; which cough sometimes happens in difficult dentition, and in the measles. It sometimes causes gibbosity and ruptures in boys; in women abortion; in adults a spitting of blood and a phthisis. Coughs that proceed from a schirrus of the lungs or other viscera, are incurable; if from driving in of exanthemata, or breakings out of the skin, it grows easy as soon as they are thrown outagain. All coughs attended with loss of sleep are bad; as also that which is

frequent, tedious, obstinate, and proceeds from a defluxion on the lungs. On the contrary, a moderate heat in the night time, with an equal breathing sweat throughout the whole body, a larger flux of urine, and the body open at the same time, a more quiet sleep, and an easier expectoration, are certain signs that the disorder is going off.

If the cough is recent, and there is no fever, nor other signs of a bastard peripneumony; or if it is not the consequence of a pleurisy or a peripneumony ill cured, by a neglect of sufficient bleeding: the patient need only abstain from wine and flesh for some days, and use the following remedy.

1. Take 10 drops of balsam of sulphur, with a bit of candied sugar; to be used twice or thrice in the day.

Recent coughs, after bleeding, are softened by a mucilage of linseed, or by any common sweet oil: But the oils are made more efficacious by the addition of a volatile alkaline salt, in this manner:

2. Take an ounce and a half of oil of olives, 6 ounces of water, 60 drops of spirit of hartshorn, an ounce of pectoral syrup: Take three or four spoonfuls every fourth hour.

If the cough will not yield to these remedies, then it will be to no purpose to rely on pectorals, especially if there is a fever along with it, or if it proceeds from a pleurisy or peripneumony; for then it is to be cured by bleeding and purging, in the same manner as the bastard peripneumony.

When there is a thin, salt, sharp defluxion, jellies are proper, and a decoction made of barley, shavings of hartshorn, viper-grass root, and liquorice; or the decoction of turpentine with sugar; and above all things, oil of sweet almonds fresh drawn.

When a tussis catarrhalis affects the whole habit or body, with a loss of appetite and a tabes, the cure must be attempted with asses milk or whey, or milk with equal parts of Selters waters, and especially riding.

In a moist, lasting, pituitous cough, the body must be kept open with manna, two ounces at least dissolved in any convenient vehicle, to which may be added, two drams of terra foliata tartari, and a few drops of oil of aniseed. If the stomach will not bear laxatives, clysters must be used.

When the cough is outrageous, saffron mixed with bezoards is very friendly to the breast; nor are storax pills, mixed with the aromatic pills, less beneficial. You may order about 6 grains of the storax pills, with a scruple of the aromatic, and give them at bed-time; in the mean while not neglecting the expectorants, oil of sweet almonds, and sperma ceti. Likewise the thebaic tincture mixt with spirit of hartshorn is not unuseful for the same purpose.

But the best opiate in this case, is the elixir paregoricum: the dose for children is from 5 to 20 drops: for adults, from 20 to 100 and upwards. It is peculiarly excellent for children in the whooping-cough or chin-cough.

The patient should, as much as possible, breathe a temperate air, shunning all salted and smok-dried meats, poignant

poignant sauces, for they render the blood and serum sharp and impure; he should also abstain from malt liquors, but more especially acid wines. The drink should be hydromel; or, if the patient is scorbutic, water alone, the cold being first taken off with toasted bread. The vulgar pour hot water upon wheat bran, and drink the infusion cold, not without success.

As to bleeding in this disease, it is necessary for those who are full of blood, and whose veins are very prominent; or when the usual excretions of it are suppressed; it is also a good preservative, though the person has past his seventieth year. Blisters may likewise be used, in obstinate cases.

Of a PHTHISIS, or Consumption of the LUNGS.

If an ulcer of the lungs consumes them so far that the whole habit of body wastes away, it is called a consumption of the lungs.

This ulcer may proceed from any case which may detain the blood in the lungs so as to change it into a purulent matter.

The causes may be referred.

I. To that temperament of the body which tends first to spitting of blood, then to an ulcer of the part where the blood has made its way through. This consists,

In a tenderness of the arterial vessels, and in the impetus of a more or less acrimonious blood. This is known from a view of the tender and fine vessels, and of the slender make of the whole body, a long neck, a flat and narrow thorax, depressed scapulae; the blood of a bright red, thin, sharp, and hot; the skin transparent, very white and fair, with a blooming red in the cheeks; the wit quick, subtle, and early ripe with regard to the age, and a merry cheerful disposition.

In such a debility of the viscera as disposes the too tenacious contents to produce obstructions, putrefactions, and to grow acrimonious, whereby the vessels are corroded, first causing spitting of blood, and then ulcers. This is discovered by a slight febricula, a little dry cough, an unusual heat, a redness of the lips and mouth, a flushing in the face; which are most apparent when the new chyle enters into the blood; a propensity to sweating when asleep, a weakness, a shortness of breath increasing upon the least motion.

In that age when the vessels have attained their full growth, and will not admit of any further lengthening; when at the same time the blood increases in quantity, acrimony, and force; which happens between the sixteenth and thirty-sixth year of the patient's age.

In an hereditary disposition to this disease.

These dispositions to a phthisis are hastened,

By a suppression of accoutumary evacuations, especially the sanguineous; as the hæmorrhoids, menses, lochia, bleeding at the nose, usual blood-letting, chiefly in the plethoric, and those who have lost a limb.

By any violent shock of the lungs, by coughing, shouting, singing, running, violent efforts of the body, anger, and wounds.

By sharp, saline, aromatic aliment, or drink; by the particular manner of living; by another disease, whence the quantity, acrimony, velocity, rarefaction and heat of

the blood are increased. Hence it frequently happens from acute fevers, the plague, small-pox, and scurvy.

II. Likewise this collection of pus may proceed from a peripneumony, which terminates in an apostem.

III. When there is an empyema formed, it may corrode, destroy, and consume the lungs, and so produce the same disease as if they were wasted away by an ulcer generated in their own substance.

The sign of an approaching phthisis is a dry cough, which may continue for some months; whereas a simple catarrh is attended with spitting, and is but of short duration. Vomiting, or a disposition to vomit after eating, excited by the above mentioned cough, is a most certain sign of a phthisis.

It invades persons from eighteen to thirty-five years of age; the whole body wastes away. There is a hectic fever, which is most apparent after meals, and is known by the quickness of the pulse, and the redness or flushing of the cheeks: The matter brought up by the cough is bloody or purulent; if it is spit into the fire, it yields an offensive smell; if into a vessel of water, it falls to the bottom. Though it is thick, it is not glutinous or tenacious, but fluid, and of different colours, viz. yellow, green, but most commonly of an ash-colour.

This disease begins with a slight pain, moderate heat, and an uneasy or oppressive tightness of the breast. When blood is brought up by coughing it is generally of a florid, scarlet colour, and frothy, and proceeds from the lungs with a remarkable noise. It is mixt with fibres, films, and small portions of arterial, venal, and bronchial vessels: The pulse is soft, small, and undulating; the breathing is difficult; and these symptoms are preceded by a saltish taste in the mouth.

Blood is coughed up from the lungs sometimes without any pain; and if there is a vessel broken, it most commonly flows out in a great quantity at the first eruption, and afterwards more sparingly.

Spitting of blood is cured by copious bleeding every third day, to the fourth time, or till the inflammatory pellicle entirely disappears. Sydenham advises the taking away 10 ounces of blood, to take the common purging potion the next morning, and at night an ounce of diacodium. Hoffman likewise advises gentle purging and pediluvia, as also putting the hands into warm water. For appeasing the orgasm of the blood, he thinks nothing better than spirit of vitriol, but more especially the tincture of roses acidulated therewith. Morton very judiciously prefers the Peruvian bark. Refrigerating thickening, styptic lenient remedies, used a considerable time, are serviceable, with which may now and then be mixed the most lenient balsamics.

Hoffman advises the following powder, as preferable to every thing else, in appeasing the spasmodic strictures of the lungs.

1. Take seeds of white henbane, and crabs-eyes, of each a dram; 12 grains of nitre; and one grain of camphor. Make them into a powder.

A prudent use of the nonnaturals is likewise necessary, that may best oppose the cause of the disease; and chiefly a proper aliment, and manner of living; a milk-diet is preferable to any other.

When the cure is performed, it will be necessary, by way of prevention, to bleed once in six months, for several years together.

But if, by reason of the violence of the disorder, or the unskillful use of styptics, there should, after the spitting of blood, arise a difficulty of breathing, which continually increases, a wandering shivering heat and redness of the cheeks, a dry husky cough, a slight hectic fever, a preternatural thirst, a weakness, or sense of weight in the breast, it is a sign that the wound from whence the blood flowed has already begun to change to matter about its lips. Then under the crust of dried blood *pus* is formed; and this collection degenerates into a latent Vomica; and that being broken, becomes an open ulcer of the lungs.

The effects of an ulcer of the lungs thus formed, are generally these which follow: An increase of the acrimony and quantity of the putrid *pus*, a dilatation and corroding maceration of the membrane or bag in which it is contained; a conversion of the blood-vessels and the bronchia into *pus*; a purulent consumption of the whole lungs, or of one of its lobes; a continual dry cough, or spittle shook off by the constant concussions of the cough; a conversion of the blood flowing into the ulcer into *pus*; an increase of the vomica in the lungs; the bursting of this vomica into the tube of the larynx; the sometimes suffocating discharge of the *pus*, or the daily coughing up of matter, which sinks in water, and is thick, sweet, fat, fetid, white, red, yellow, livid, ash-coloured, or streaked, and which, put into the fire, has the smell of burnt flesh. Sometimes the vomica breaks into the cavity of the thorax; from whence proceeds difficulty of breathing, and the other symptoms of an empyema. Then the respiration grows exceeding bad; the chyle and the whole mass of blood are converted into *pus*; the usual method of nourishment is destroyed, the solids continually consume and waste away; a hectic fever appears, with a small languid pulse, and the heat in the upper parts intense, the cheeks look red, and the face hippocratic. Generally there is an inexpressible anxiety towards the evening; an unusual thirst; profuse nocturnal sweats; red pustules; a swelling of the feet or hands on the side affected; excessive weakness; a hoarse voice; a falling off of the hair; an itching throughout the body, with watery pustules; a debilitating diarrhoea, with yellow, fetid, purulent, cadaverous stools; a suppression of the spitting; and then death.

Hence the following prognostics may be formed.

An hereditary phthisis is the most dangerous of all, and is incurable unless the spitting of blood be prevented.

A phthisis from external violence, that is, proceeding from spitting of blood caused thereby, is the slightest of all.

A phthisis in which the vomica breaks suddenly, and the patient easily brings up a white, concocted, smooth *pus*, and in quantity proportionable to the ulcer, without thirst, and with a good appetite and digestion, due secretions and excretions, is curable, though with difficulty.

Heavy, solid, sinking, sweet spittle, with night-sweats, livid cheeks, paleness of the face, the nostrils pinched up, sinking in the temples, incurvation of the nails, falling off

of the hair, and a colliquative diarrhoea, are signs of approaching death.

When a vomica is known to be formed in the lungs, then the physician must endeavour to ripen and break it; which is to be done by milk diet, riding on horseback, warm vapours and expectorants: Which done,

1. The blood must be guarded and defended against the purulent infection, by remedies which are moderately and agreeably acid and salisih, by vulnerary herbs. smooth balsamica given in various forms, in great plenty, and continued a long time.

2. The ulcer must be cleared as soon as possible from the purulent matter, the lips of it cleaned and consolidated, which is to be done by liquid medicines, by things which promote coughing by motion, riding, country-air; these are expellents. The cleansers are detergent balsamics, used inwardly and outwardly. The consolidators are paretogics.

3. The aliment must be such as requires the least force to make it pass freely through the lungs, and be there assimilated, and at the same time be fit for nourishment. Asses milk is very suitable to this intention, as also buttermilk.

Small repeated bleedings are not only beneficial in old coughs, threatening consumptions, but also after purulent spitting and hectic symptoms have appeared. The quantity of blood to be drawn is from four to seven or eight ounces, once in eight or ten days.

Setons, or issues made in the side of the part that is most affected, are very beneficial.

We must endeavour to diminish the defluxion on the lungs, by bleeding and gentle purging, as well as pectorals, accommodated to the various states of the distemper, viz. by thickening medicines and attenuants, and such as temperate the hectic fever, with emulsions and asses milk, &c. and lastly, by healing the ulcer with balsamica, as opobalsamum; the dose is 20 drops upon sugar; but this is not to be taken before due evacuations have been first made.

After evacuations. great care must be taken that the cough be appeased, lest the lungs should be weakened by the continual agitation.

The most sovereign remedy to restore the lungs to their pristine vigour is to get on horseback every day; and he that will put himself upon this exercise for a cure, need not be tied down to any strict rules of diet, nor be debarred from any sort of meat or drink, since the whole stress of the matter depends wholly on the constant and continual exercise of riding. Long sea-voyages have of late been greatly recommended.

In the first stage of this disease, when the lungs, trachea, and glands, throughout the whole pulmonary tube, are stuffed with a pituitous matter, separated from the mass of blood, and the patient is afflicted with a continual cough, especially in the night-time, all proper methods must be used to stop the influx of this catarrh, and to concoct the humours already impacted.

First, Blood must be taken from the arm, from six to ten ounces, if the patient is plethoric, or accustomed to bleeding; this is to be repeated once, twice, or thrice, at proper intervals, especially if the flux of serum is like a suffocating

suffocating catarrh, together with the copious expectoration of a crude plegm; or where there is an athmatic difficulty of breathing, a pain in the side, or the signs of any disposition to a rheumatism, a pleurisy, or a peripneumony.

After bleeding, especially if there is a nausea, or an inclination to vomit, it will be necessary to give an emetic with oxymel of squills [or ipecacuanha wine,] which will sometimes stop the progress of an incipient phthisis. The emetic, if it agrees with the patient, and there is occasion for it, may be repeated every third or fourth day. The best time is towards the evening; and after the operation is over, an opiate will be proper.

Nor must those remedies that soften, lubricate, thicken and concoct the phlegm, be omitted; such as sugar candy, barley sugar, old conserve of roses, juice of liquorice, the white and black troches of the London dispensatory; fresh butter in water-gruel, sweet oil or oil of sweet almonds, especially linseed oil cold drawn, of which the patient may take a spoonful every hour, unless there is a diarrhoea, or any other contra-indicating symptoms. He may also eat raisins and figs.

The air should be pure, far from bogs and marshy places, and the smoke of sea-coal; the aliment light of digestion; the drink small, for spiritous liquors should be avoided. The patient should use exercise, and keep his mind as free from passions as possible.

The second stage of this disease may be reckoned from the first formation of the tubercles, till they begin to inflame and putrify, that is, while they remain in a crude state. This is known from the increase of the hectic fever; from the wasting and flaccid state of the muscular flesh, from the dryness of the cough, for the spitting considerably abates; and from the great weight and oppression which is continually felt in the breast.

In this stage, all evacuations by vomit, stool, and sweat, are pernicious; for they increase the fever, and accelerate the consumption. Nor is bleeding otherwise proper, than as it prevents an inflammation, and then it must be used with a sparing hand, when there are pleuritic pains, or the patient hath caught a fresh cold.

Besides alterative medicines, taken in small quantities, and at stated times, endeavours must be used to cool the febrile heat of the blood, and decrease the quantity of the noxious humours. The diet must be such as will obtund the acrimony of the humours; as partridges, mountain-birds, poached eggs, oysters, calves-feet and jellies, and soups made therefrom; also craw-fish and other shell-fish, and broths made of their flesh. Likewise spaw-waters, pectorals, hydromel, a milk diet, asses milk, milk-water, millepedes, snails, and the like; together with issues, shaving the head, and proper plasters.

In the third stage of this disease little hopes remain of a cure, unless the ulcers are small and benign.

In this state of the disease, opiates should be sparingly used, even though the cough and want of rest require them, because they not seldom bring on sudden death. Jellies and broths are likewise to be directed; for, in short, there is now more help to be expected from the kitchen than from the apothecary's shop.

The diet should be water gruel, ptisans of scalded apples, posset-drink, stoned raisins and liquorice, table-beer warmed with a toast, and the like. When the fever is on the decline, chicken broth, poached eggs, &c.

If there is occasion, the body must be loosened with clysters of-sugared milk, with chamomile flowers, and repeated as occasion requires; then take away ten ounces of blood on the side affected, which should be boldly repeated every, or every other day, according to the urgency of the symptoms.

In colligative sweats, pearl juleps may be freely given, to which may be added chalk, corals, dragon's blood, or other astringents. But the Peruvian bark for this purpose, is much better than any other medicine whatever. The patient should not be permitted to sleep too long, the bed-cloaths should be light, and he should be removed to fine suble air.

Of the NERVOUS CONSUMPTION.

A nervous atrophy or phthisis, is a wasting of the body, without any remarkable fever, cough, or difficulty of breathing; but is attended with want of appetite and a bad digestion; whence the whole body grows languid, and is continually falling away.

At first the body is œdematous, and as it were stuffed with a vapid chyle; the face looks pale and bloated, and the stomach lothes every thing but liquids. The patient is forced to keep his bed sooner than the progress of the decay of his flesh seems to require. The colour of the urine is uncertain, but it is generally very red and small in quantity; sometimes it is pale and copious.

No considerable fever is discernible either by the pulse, heat, or thirst, though the urine is ever so red.

The causes of this disease are generally violent passions of the mind, a too free use of spiritous liquors, and unwholesome air.

Stomachic and nervous remedies are only to be depended upon; such as, chalybeates, antiscorbutics, cephalics, and bitters. If the body be colic, two ounces of tinctura sacra may be taken every fourth evening, and from 30 to 40 drops of elixir aloes, in a glass of white-wine with bitters, before dinner. The elixir of vitriol is excellent in this case, 20, 30, or 40 drops is a dose, in any convenient vehicle, once, twice, or thrice a day. Also about half an ounce of the chalybeate wine, in some proper liquid, in the winter; in the summer, the spaw waters: the usual drink may likewise be made bitter with the *vinum amarum*; but nothing strengthens the stomach more than a decoction of wormwood.

Sometimes the patient may take eight or nine drops of opobalsamum, or spirit of hartshorn, or of sal ammoniac, as friendly to the nerves; nor must he forget exercise and cheerful company, with other diversions.

Of an EMPYEMA.

An Empyema is a collection of purulent matter in the cavity of the thorax, between the lungs and the pleura, which always supposes the breaking of a vomica into the said cavity.

Such are the vomice or abscesses of the lungs, proceeding from inflammations, from spitting of blood, from

a thick matter which cannot be expectorated. Of the pleura, from an inflammation, from a wound therein, healed outwardly but open inwardly: from a bruise, or a concealed rupture of it, turning to pus. Of the diaphragm, when, after an inflammation, it suppurates, and breaks on its upper part. Also of the mediastinum and pericardium affected in the like manner.

An empyema may be foreseen from an inflammation of any of the above mentioned parts, which is not terminated and resolved by concoction, revulsion, a crisis, or medicines; but is followed by shiverings, a febrile increasing at night, a wandering heat, a sense of heaviness in the part that was pained, a difficulty of breathing, a want of appetite, and an unusual thirst.

An actual empyema is known from twenty days being elapsed since the inflammation began, without expectoration of the matter; from the signs of a vomica in the five abovementioned parts disappearing; from a new pain, cough, difficulty of breathing, and spitting, arising, and afterwards going off; from a dry cough, a weight on the diaphragm, not being able to lie but on one side, a noise made by the fluctuation of the pus, upon moving the body; from a slow fever, a flushing in the cheeks, hollow eyes, heat in the ends of the fingers, crookedness of the nails, and a swelling of the abdomen.

The consequences of this disease are, a continual accumulation of pus from the ulcer not yet healed; the matter increasing in its acrimony, putrefaction, rank smell, and thinness, by being thus up in a hot, moist place; an impediment in raising the diaphragm and extending the lungs; a shortness and difficulty of breathing, and not easily performed unless in an erect posture, a dread of suffocation when laid down; an inability of lying, but on the affected side; a constant dry cough, with anxiety; a maceration and corrosion of the lungs, pleura, diaphragm, pericardium, and even of the heart itself, converting them gradually into filthy corruption; whence a hectic fever, quick, small pulse, constant redness of the cheeks, loss of appetite, perpetual thirst, extreme weakness, and fainting fits. Hence all the fluids become unfit for nutrition, circulation, or any other office: The consequence of which is, a wasting of the whole body; a putrefaction of the fluids, which may be discharged through the corroded lungs, or carried downwards by a fatal sanious diarrhoea; night-sweats; pustules in the face, crooked nails, a shining yellowness of the skin, and a hippocratic countenance.

The cure of this disease is different, according to its different cause and state.

When a vomica or abscess is known to be formed in any of the parts before mentioned, all endeavours are to be used, that it may be speedily broken and determined to the outward parts, which must be attempted by actual or potential cauteries, or by incision and proper motion.

When the vomica is actually broke, then it is to be evacuated by the mouth, if nature seems to encourage it; or by urine, if there appear any signs in it of passing that way; or by an aperture of the thorax by a proper instrument. See SURGERY.

In general, all inflammations of the lungs or pleura are

followed by an adhesion of these parts, which allow nature to make a passage externally: And it is common in abscesses of the pleura and intercostal muscles to find them break outwardly; nor is it uncommon even in the lungs. Therefore, when there is an adhesion, no other operation is necessary than to open the tumour with a lancet, when the pus is formed; and if the suppuration is so plentiful as not to admit the healing of the outward ulcer, it may be kept open with a hollow tent.

Hoffman gives an instance of a person, who, after a peripneumony, fell into an empyema, and was cured by taking milk boiled with sugar of roses. The quantity was three pints a-day. As also balsamic pills made of flowers of sulphur, oil of sweet almonds, sperma ceti, Venice turpentine, saffron, and oil of aniseed. Likewise a powder made of crabs eyes, sperma ceti, sugar, myrrh, liquorice powder, and bole armoniac.

Of the SCURVY.

THIS distemper chiefly affects the inhabitants of cold northern countries, and especially those who live in marshy low, fat and moist soils, near stagnating water, whether fresh or salt. Those who live idle sedentary lives are most subject, chiefly in the winter, to the attacks of this disease; as also those who feed upon salted and smoked flesh or fish, sea biscuit, stinking water, fermented farinaceous vegetables, pease, beans, sharp salt old cheese: likewise those who are subject to melancholic, maniacal, hysterical or hypochondriacal disorders.

It is known by spontaneous weariness, heaviness of the body, difficulty of breathing, especially after bodily motion; rottenness of the gums, a stinking breath, frequent bleeding of the nose, difficulty of walking; sometimes a swelling, sometimes a falling away of the legs, in which there are always livid, plumbeous, yellow or violet-coloured spots; the colour of the face is generally of a pale tawney.

The first state of this disease begins with unusual laziness, spontaneous weariness; the patient loves to be in a sitting or lying posture; there is a pain in all the muscles, as if he was over tired, especially of the legs and loins; when he wakes in the morning, all his joints and muscles seem to be tired and bruised.

In the second state, the gums swell, grow painful, hot and itching, and bleed upon the least pressure: the roots of the teeth become bare and loose; he feels pains in all the external and internal parts of the body, imitating distempers proper to the various parts.

In the third state, the gums at length grow putrid, with a cadaverous smell; when they are inflamed, blood distils from them, and a gangrene ensues; the loose teeth by degrees grow yellow, black, and rotten; the sublingual veins become varicose, and like rings; there are often fatal hæmorrhages, which break out from the external skin, without any appearance of a wound from the lips, gums, mouth, nose, lungs, stomach, liver, spleen, pancreas, intestines, womb, kidneys, &c. Obstinate ulcers arise, of the very worst kind, which no applications will cure, and which are apt to turn to a gangrene; they break out in all parts, but especially the legs, and are attended with a stench. There is a kind of anitch and dry scabs, with

with a dry and mild leprosy. The blood drawn from a vein is black, grumous, thick, and yet wants its due consistence in the fibrous part; the serum is salt, sharp, and abounding with a yellowish green mucus on its surface. There are gnawing, rending pains, quickly shifting from place to place, which grow more violent in the night, affecting all the joints, bones, and viscera.

In the fourth state, there are fevers of various kinds, which bring on an atrophy; sometimes diarrhoeas, dysenteries, or violent stranguries; as also faintings and mortal anxieties, a dropy, consumption, convulsions, trembling, a palsy, contractions, black spots, voiding of blood upwards and downwards, a putrefaction and consumption of the liver, spleen, pancreas, mesentery. Now the contagion spreads very quick.

The first sign of the approach of this disease is commonly a change of colour in the face, which becomes pale or yellowish, and bloated, with a listlessness, and an aversion to exercise. The caruncles of the eyes appear of a greenish cast, and yet in other respects the patient seems in perfect health. However, the change of colour in the face does not always precede the other symptoms, though it constantly attends them. Then an universal lassitude supervenes, and a stiffness and feebleness of the knees, with a difficulty of breathing on the least motion. Soon after this there is an itching of the gums, which swell, and are apt to bleed on the least friction. Then they become livid, soft and spongy, and afterwards extremely purid and fungous. This rottenness of the gums is an inseparable sign of this disease. These are not only subject to bleed, but there are hæmorrhages from different parts of the body.

The skin is dry throughout the whole course of this disease, except towards the last, and in many it is rough. In some it appears like the skin of a goose; but it is most frequently smooth and shining. It is stained with blue, purple, livid, or black spots; some of which are small, and others of a hand's breadth, when the disease is advanced. They are chiefly on the legs and thighs, but sometimes on the arms and trunk of the body. Some have a swelling of the ankles in the evening, which disappears in the morning. In a little time it advances gradually up the leg, and the whole member becomes œdematous. Hurts, bruises, wounds healed up, and fractured parts, always become scorbutic first. Old ulcers will emit a thin fetid sanies, mixed with blood, and at length coagulated gore will lie on the surface of the sore like a cake. As the disease increases, they shoot out a soft, bloody fungus resembling bullock's liver, which sometimes will rise to a monstrous size in a night's time. The slightest bruises and wounds of scorbutic persons degenerate into such ulcers, and are easily distinguished from all others, by being purid, bloody, and fungous.

To prevent the scurvy at land, it will be proper to chuse a warm, dry, pure air, with a diet of easy digestion, consisting chiefly of a due mixture of animal and vegetable substances; for those are most liable to it who live in marshy, wet soils, and in places subject to great rains and fogs; or in damp, low apartments, unless they keep constant fires, and their chief food be flesh broths, with plenty of fresh greens or vegetables, and well-baked

bread made of wheat-flour; as also a cheerful glass of some good wholesome fermented liquor. Cleanliness, entertaining amusements, and moderate exercise, will also be good preservatives in these cases. In garrisons, the soldiers should be kept as dry, clean, and warm as possible, and their provisions should be as wholesome as can be procured, with plenty of good vegetables, particularly fallads of garden-creffes.

The best method of preventing the scurvy at sea will appear from the effects which Dr Lind has observed several medicines have had, especially those which have been greatly recommended as preservatives. On the 20th of May 1747, being on board the Salisbury at sea, he took twelve scorbutic patients under his care. They had putrid gums, spots, and lassitude, with weakness of their knees. They had a proper apartment in the forehold: their diet was water-gruel sweetened, in a morning; sometimes mutton broth for dinner, sometimes light puddings, boiled biscuit with sugar, &c. and for supper, barley and raisins, rice and currants, sago and wine, and the like. Two of these were ordered each a quart of cyder in a day; two others twenty-five drops of elixir of vitriol, three times a-day, upon an empty stomach, using a gargle acidulated with the same. Two others took two spoonfuls of vinegar three times a-day; having their gruels, other food, and gargles, well acidulated with it. Two of the worst patients, with the tendons of the ham rigid, were put under a course of sea-water, and drank about a pint every day, more or less, according to its operation, which was intended to be as gentle physic. Two others had each two oranges and one lemon given them every day, which they eat with greenfish upon an empty stomach, at different times. This course was continued but six days, because no more fruit could be allowed. The two remaining patients took the bigness of a nutmeg, three times a day, of an electuary made of garlic, mustard seed, balsam of Peru, and gum myrrh; using for common drink barley water well acidulated with tamarinds; by a decoction of which, and cream, they were gently purged three or four times during the course.

The oranges and lemons had the best effect; for one of those who had taken them, was at the end of six days fit for duty; and he took nothing more but a gargle of the elixir of vitriol for his gums, which were not quite found, and so recovered his health entirely. The other being more recovered than any of the other patients, was appointed to look after them. Next to the oranges the cyder had the best effects, though it was not very good, being prick'd; for those who drank it were in a fairer way of recovery at the end of the fortnight, the time allowed for making the experiments, than any of the rest. Elixir of vitriol did no good unless as a gargle, nor yet any of the rest of the medicines. Oranges are preferable to lemons; for by these the lord Anion's people were so speedily and surprisingly recovered at the island of Tinian. Besides Mr Murray affirms, from experience, that oranges and lemons, when properly and sufficiently used, are an infallible cure in every stage and species of this disease, if there is any degree of natural strength left, and where a diarrhoea, hientery, or dysentery, are not joined to

the

the other symptoms. He observes farther, that at the island of St Thomas, fifty men belonging to the Canterbury, and seven to the Norwich, who were in all the different stages of this distemper, were cured in little more than twelve days.

But as oranges and lemons are apt to spoil, let the juice of these fruits be well cleared from the pulp, and depurated by standing some time; after which it may be poured off from the gross sediment. Let it then be poured into any clean open vessel of china or stone ware, which should be wider at the top than at the bottom, that it may evaporate more readily. But a china basin or punch-bowl is most proper, on account of the form. Put this into a pan of water over a clear fire; let the water come almost to boil, and continue nearly in that state, with the bowl full of juice in the middle of it, till the juice is found of the consistence of a thick syrup when cold. The slower the evaporation of the juice is, the better; that is, it ought to continue twelve or fourteen hours over the fire: When it is cold, it is to be corked up in a bottle for use. Two dozen of good oranges weighing five pounds four ounces, will yield one pound nine ounces and a half of depurated juice; and when evaporated, there will remain five ounces of extract, which in bulk will be equal to less than three ounces of water. So that twelve dozen of oranges may be put in a quart bottle, and preserved several years. The same may be said of lemons. When this is mixed with water and made into punch, few are able to distinguish it from the fresh juice mixed up in the same manner. However, when the fresh fruit can be had, the fragrantcy of the peel may contribute somewhat to the cure of the scurvy; and when these are wanting, the same thing may be obtained from a few drops of their essence, or the aromatic oil contained in their rinds; and if a small quantity of this be added to the extract, it will give it the smell and fragrantcy of the fresh fruit in great perfection. Or rather add a little of the outer peel to the extract a little before it is taken off the fire, and then the nicest taste will not be able to distinguish the difference between the fresh fruit and this. The virtues of this extract, thus made, lie in so small a compass, that a bottle will serve one man at sea several years; for in the making of it there is little or nothing flies off besides the water.

It will likewise be of great use to seamen to have gooseberries, and the like, preserved in bottles in the same manner as the pastry-cooks; as also small onions pickled in vinegar, cabbage, french beans, &c. may be preserved, by putting them in clean dry stone-jars, with a layer of salt at the bottom, then a thin layer of the vegetable covered with salt, and so alternately till the jar is full. Then the whole must be pressed down with a weight, and its mouth quite stopped that no air or moisture may enter. Thus the vegetable may be kept fresh and green for a whole year. At the time of using, the salt is to be washed off with warm water. This is the manner by which they preserve that never-failing remedy, Greenland scurvy-grass. Every common sailor ought to lay in a stock of onions, for they are a great preservative at sea. The Dutch sailors are preserved from the scurvy by pickled cabbage. Portable soup may be carried to all

places. When the scurvy begins to make its appearance, sailors should be abridged in the same degree of their allowance of beef and pork, and eat them with mustard and vinegar; but the pease ought always to be served out in full allowance. It must be observed likewise, that a soup of boiled cabbage and onions will cure an adventurous scurvy in its first stage, either at land or sea, in any part of the world.

Besides fresh and preserved fruits and vegetables, fermented liquors of all sorts are good, but more particularly cyder. Among these are included many wines of every kind; or the juices of fruits may be fermented with ale. Poor people that winter in Greenland under vast disadvantages in point of air and diet, preserve themselves from the scurvy by spruce-beer, which is their common drink. Likewise the simple decoction of fir-tops has done wonders. The shrub black spruce of America makes this most wholesome drink just mentioned, and affords a balsam superior to most turpentine. It is of the fir kind. A simple decoction of the tops, cones, leaves, or even of the green bark or wood of these, is an excellent antiscorbutic; but perhaps it is much more so when fermented, as in making spruce-beer. This is done by molasses, which by its diaphoretic quality makes it a more suitable medicine. By carrying a few bags of spruce to sea, this wholesome drink may be made at any time. But when spruce cannot be had, the common fir-tops used for fuel in the ship should be first boiled in water, and then the decoction should be fermented with molasses; to which may be added a small quantity of wormwood and root of horse radish. The sweeter it is drank, the better. When other things are wanting, tar-water may be fermented in the same manner.

Those who have been weakened by long fits of illness should have the scurvy prevented by panada of bread newly baked, with a few drops of the extract of lemons, and a spoonful of wine; as also oatmeal and rice, gruels, flummery, stewed barley, with raisins or currants, sago, and wine, &c. But more particularly pickled cabbage, and small onions boiled with the portable soup made weak. Most of their food ought to be acidulated with orange or lemon juice; and then as their strength increases, they should be indulged with more solid food. But before this, they should have a small quantity at a time and often, and they should be brought back to their labour by little and little. Exercise on a deal-board, with the ends laid on two chests, will be very proper; because it promotes the circulation, and strengthens the fibres, without any loss of spirits.

Bad air of any kind has a bad effect upon a ship's crew; to remedy which, a red-hot loggerhead should be put into a bucket of tar, and moved about, so that all the ship once or twice a day should be filled with this wholesome antiseptic vapour. In a moist air, whatever promotes perspiration is proper; such as dry linen, cleanliness, using the flesh-brush, garlic or raw onions before going into the rain, and keeping the bedding dry. Plenty of mustard and onions should be used with their vituals.

The cure of this disease has been in a great measure anticipated by the means of prevention, inasmuch that little remains to be said about it. The diet should be

light

light and easy of digestion, such as broths or soups made of flesh meat, with plenty of vegetables, such as cabbage, coleworts, leeks, onions, &c. The bread should be fresh and well baked; and fallads of all kinds are beneficial, but more particularly dandelion, sorrel, endive, lettuce, fumitory, and purslane; to which may be added, scurvy grafs, cresses, or the like, to correct the cooling qualities of the former. Summer fruits are all good, as oranges, lemons, citrons, apples, &c. The drink may be good sound beer, cyder, or Rhenish wine. Physic is never necessary if the fresh broths and greens keep the belly open, and pass freely by urine, sweat, and perspiration. If otherwise, the patient may take a decoction of tamarinds and prunes with a diuretic salt; and on intermediate days he may be sweated with camphorate boluses of theriac. and warm draughts of a decoction of the woods, of twelve or fifteen grains of the squill pills of the Edinburgh dispensatory.

Milk of all sorts, if it agrees with the constitution, will be very beneficial, as well as whey, which is preferable. Sal polychrest is use as a mild purgative and excellent diuretic. The scorbutic juices, qualified with the juice of Seville oranges, are proper, especially mixed with the clarified whey, with sweating twice or thrice a week with the said juice mixed with sack-whey; for this is an evacuation which scorbutic persons bear the best. When there is no danger of an hæmorrhage, warm baths, with rosemary, marjoram, thyme, &c. may be good. In the winter-time, genuine spruce-beer, with lemons and orange juice, is proper; or antiscorbutic ale, made of an infusion of wormwood, horse radish, mustard-seed, and the like; and it may be made laxative with the addition of senna. It must be drank while pretty fresh or new. Van Swieten says, he has often seen whole families cured of the scurvy, in Holland, by the use of a cask of ale, in which were put heads of a red cabbage cut small, twelve handfuls of cresses or scurvy-grafs, and a pound of fresh horse-radish previously infused.

When the gums begin to itch and are spongy, use a gargle of the bark infused in brandy. When the putrefaction increases, use barley-water and honey of roses, acidulated with a mineral acid. The fungus must be kept down, and, when necessary, cut away. The ulcers of the gums must be checked with a touch of spirit of salt, or oil of vitriol diluted. When the legs are swelled, or œdematous, gentle frictions are to be used at first with warm flannel, or with woollen cloths charged with the fumes of benjamin and amber, provided the swelling be small, soft, and not very painful, rolling them up afterwards with an easy bandage from below upwards: But if they are much swelled, stiff, and painful, they must be fomented with a discutient fomentation, or rather the steam of the fomentation should be received through a blanket rolled round the limb. This operation, repeated night and morning, will render the contracted joints supple. After this has been continued for half an hour, the parts are to be anointed with palm oil. If a vegetable diet does not reduce the limb, sweat it with burning spirits, or bags of warm salt.

Ulcers of the legs must be treated with very gentle compression, to keep the fungus under; and the same ap-

plications must be used as to the rotten gums. Mr. Murray has found a strong tincture of the bark of great service in scorbutic ulcers. In dangerous hæmorrhages the mineral acids must be given by a little at a time and often; such as the spirit or elixir of vitriol, together with small doses of the Peruvian bark.

A scorbutic diarrhœa should not be suddenly stopt at sea, but the peccant humour must be gently evacuated with small doses of rhubarb, and the perspiration kept up with a little theriac or diacordium, with other warm diaphoretic and strengthening medicines. In extreme cases, opium may be given more freely. The diet must be glutinous and subaltringent, with strong rough red wine diluted. Sometimes five grains of alum may be given with the diacordium, especially when blood is evacuated in great quantities. The most effectual remedy in scorbutic dysenteries is an infusion of tpecacuanha in brandy, given in small doses, and often repeated.

Physicians refer the different symptoms of this disease to different salts; but their different and far-fetched corrections of these salts are plainly ridiculous. Water is the known solvent of all salts, and this intention will be best answered by pure and light simple water. The universal remedy for a scurvy consists in mineral waters.

After mineral waters, nothing is more effectual in correcting a scorbutic acrimony than a milk diet, or whey alone, or impregnated with the juices of antiscorbutic herbs, such as scurvy-grafs and water-cresses.

As to evacuations, bleeding should be used with the greatest caution; and none but the gentlest purges should be given, such as senna, rhubarb, or manna. The diuretics should not be stronger than the decoction of the roots of parsley, celery, fennel, and asparagus. The safest diaphoretics are, dulcified spirit of nitre, flowers of sulphur, ethiops mineral; infusions, in the manner of tea, of Paul's betony, carduus benedictus, scordium, and elder-flowers.

In the hot or alkaline scurvy, scurvy-grafs is too warm to be administered alone, and should be corrected with acids, such as wood-sorrel, the juices of citrons, oranges, barberries and pomegranates. Or mix the conserve of scurvy grafs with an equal quantity of the conserve of wood-sorrel, and give it twice or thrice a day, with some antiscorbutic water. This should be accompanied with milk-meats, almond-emulsions, barley-broths, water-gruel, chicken-broths, with endive, lettuce, sorrel, and cresses, interposing, at proper intervals, gentle laxatives and diuretics.

When the scurvy proceeds from muriatic salts, which happens to those who live on smoked or high salted fish or flesh, and have corroding ulcers, a stinking breath, putrid gums, a thick and saltish urine, as is generally observed in old sailors; then whey long and copiously drank, produces happy effects; as also citrons, China oranges, and ripe fruits; whereas spirituous and volatile antiscorbutics are generally detrimental. Hoff.

But if crusty black ulcers require external remedies, we should only use preparations of the yolk of an egg, myrrh, oilibanum, saffron, oil of roses, and Peruvian balsam. When there is an excessive impurity of the humours tending to putrefaction, scarifications will induce

a gangrene, which may be prevented by lime water, exalited with camphorated spirit of wine and sal amoniac.

But fomentations and cataplasms of the common hemlock, frequently repeated and duly continued, are found more effectual than all other remedies.

Of the DROPSY.

DROPSIES are of various kinds; but those usually treated of by authors are the anasarca, ascites, and tympany.

When the lymph stagnates throughout the whole habit of the subcutaneous fat, or is shed therein, it produces an anasarca, which extends itself also to the abdomen and scrotum.

When the water is collected in the duplicature of the peritonæum, in the cavity of the abdomen, between the peritonæum and the viscera of the abdomen, or in the dilated cavities of the glands and vessels contained in the abdomen, it is called an ascites. If the dropsy is owing to the rarefaction of some steam or vapour, arising from water, pus, ichor, or air, pent up and heated till they putrefy, then it is a tympany.

The cause of these diseases may be, a family disposition thereto; a salty drinking too great a quantity of cold water, and its not being evacuated upwards or downwards, or by sweat, or urine excited by heat or motion; acute diseases, especially the most ardent, attended with unquenchable thirst, or otherwise; a lenterious dysentery of a long continuance; all oblitinate obstructions of the viscera; and a scirrhus of the liver, spleen, pancreas, mesentery, kidneys, womb, or intestines; the jaundice; a violent quartan ague of long duration; a lenterious; a diarrhoea; a long dysentery; the coeliac passion, an empyema; a consumption; the gout; too great evacuations, chiefly the blood; the drinking of sharp, fermented, and spirituous liquors; the feeding on tenacious and hard aliment; very large and numerous hydatides hanging in the cavity of the abdomen; melancholy; the scurvy, and the like.

The first sign of the approach of this disease is the swelling of the feet and ankles, which in the evening will pit, if pressed with the fingers; which swelling disappears in the morning, especially if there begins to be a difficulty of breathing. And yet it must be remembered, that pregnant women, or whose menses are stopped, as also when suddenly freed from an inveterate asthma, are affected with the like swelling. When the feet and legs are distended to the utmost, the waters rush into the abdomen, and cause it to swell by little and little, till at length the more noble viscera are affected therewith, and the patient is soon overwhelmed with the deluge. In proportion as the diseased parts increase in bulk, the rest fall away: at the same time the difficulty of breathing, paucity of urine, and intense thirst, the three principal symptoms, grow more intolerable.

When the abdomen is swelled, it will found, when struck, if the disease is a tympany. In the ascites there is a noise of the fluctuating water upon bodily motion, unless the waters are inclosed in a cystis or bag.

Besides the above-mentioned symptoms, there is a

heaviness, a torpor, a costive body, and at length a slow fever; the patient never sweats. In process of time, the stagnating waters, being pent up in a hot place, become acrimonious; hence ulcers, gangrenes, bleeding at the nose, a protuberance of the navel, a mortification of the viscera, and death.

The curative indications in an anasarca, as well as in an ascites, are to restore the humours to their natural fluidity; to invigorate the languid circulation; to brace up and strengthen the relaxed solids; to promote the secretions; and to carry off the redundant stagnating juices.

Strong drastic purges, steel medicines, absorbents, detergents and stomachics, are best suited to answer these intentions.

The first thing to be done is to evacuate the serous humours by cathartics.

There are two things of uncommon efficacy in the dropsy; these are, elaterum and antimonial wine, especially for those which are not easily purged; two grains of the former is a proper dose for most constitutions.

As for the antimonial wine, an ounce and a half, or two ounces, as the patient's strength will admit, given in the morning, will in due time free the abdomen from the load of water. If it does not purge downwards as well as upwards, mix it with syrup of buckthorn after the third or fourth dose.

Some greatly recommend Bontius's pills for the dropsy, the dose of which is from half a scruple to a scruple; but Heister prescribes them from half a dram to a dram.

Mayrne affirms, that mercurius dulcis, without doing any mischief to the body, acts directly upon the morbid cause, and if possible destroys it. If a salivation follows, it is not dangerous, but may be prevented if the mercurial be joined to an active cathartic.

Many praise the juice of the root of iris palustris lutea; and we have an instance of its efficacy in a most deplorable dropsy, in the *Med. essays*; eighty drops of which were given every hour in a little syrup of buckthorn, which brought away many quarts of water by stool the first night; the quantity was daily increased till it came to two drams, and at last was mixt with a fourth part of the syrup, and given by spoonfuls.

Sometimes purgatives are to be entirely omitted, when the patient is of a weak constitution, or women subject to vapours; and then diuretics only should be made use of; among which, those are most powerful which consist of lixivial salts.

Boerhaave likewise proposes to attenuate the humours by small doses of mercurial preparations, to be taken every other morning, in a little pulp of a roasted apple; as half a grain of turbith mineral, with ten grains of white ginger; or one grain of red precipitate, with six grains of nutmeg; or seven grains of calomel, with eight of winter's bark.

Some have been cured by a pertinacious abstinence from all liquids, living upon sea biscuit with a little salt, and a very little rich wine. Externally, frictions of the parts have been found beneficial.

Of the Hydrocele, or Dropsy of the Scrotum.

THE hydrocele, called the dropsy of the scrotum, *hernia aquosa*, and the dropsy of the testicle, is an aqueous tumour of the scrotum. Though authors mention several kinds, there are but two. The first is, when the water is contained in the tunica vaginalis; the second, when it is contained in the cellular membrane of the scrotum. This last is almost always complicated with an anasarca, a kind of dropsy which consists in the extravasation of the water which lodges in the cells of the *membrana adiposa*. The hydrocele in this case is known without any difficulty; for the skin is shining and soft, yielding easily to a slight impression, which will remain pitted for some time; the penis is also sometimes prodigiously swelled by the liquor which insinuates into the cellular membrane. There are none of these symptoms in the dropsy of the tunica vaginalis.

In the dropsy of the cellular membrane of the scrotum, some recommend the puncture with a trochart; others, to make small apertures here and there with the point of a lancet; others, to put a small skean of silk through the skin with a needle, and to let it remain as a seton, till all the water is drained off. But the two first methods yield very little relief, and the last may be more likely to induce a gangrene. Nor is there occasion for any operation at all, because the cellular membrane of the scrotum is nothing but a continuation of the *membrana adiposa*; and therefore scarifications made in the skin of the small of the legs will effectually empty the scrotum.

Yet sometimes there falls so great a quantity of water into the scrotum, that the distension is very painful, threatening a mortification. Likewise the prepucis very often is so excessively dilated and twisted, that it hinders the patient from making water.

In these cases there should be an incision made on each side the scrotum, three inches in length, quite through the skin, into the cells which contain the water; and likewise two or three, half an inch long, in any part of the penis, with a lancet or knife.

The dropsy of the tunica vaginalis is caused by an excessive accumulation of a serosity, which is naturally separated in the internal surface of that tunic in a small quantity, to moisten and lubricate the testicle. Authors have hitherto distinguished them into two sorts; the one on the inside of the tunica vaginalis; and the other on the outside, between that and the scrotum, which they suppose to proceed from water in the dropsy ascites. But anatomy shows the absurdity of this opinion: for besides that persons afflicted with this kind of hydrocele have seldom any other dropsy, and those who have the ascites are free from this hydrocele, the tunica vaginalis is like a purse quite shut up on the outside of the abdomen, so that the water cannot insinuate into it from any part.

As to the notion that the water falls from the abdomen into the interstice between the tunica vaginalis and the scrotum, it is equally impossible. For though in the intestinal rupture the gut falls into this place, yet it brings the peritoneum along with it, and that will prevent the egress of the water. This is a circumstance the ancients were unacquainted with, and the moderns have not sufficiently attended to.

This disorder is seldom attended with pain in the beginning, contrary to what happens in the hernia of the epiploon, and of the intestine; nor is it often the effect of any accident. It never diminishes when once begun, but generally continues to increase; but in some persons not so quick as in others. In one person it will grow to a very painful distension in a few months; in another it shall not be troublesome in many years; nay, it shall cease to swell at a certain period, and afterwards continue in that state without any notable disadvantage. But this is rare.

In proportion as it enlarges, it becomes more tense, and then is said to be transparent: but this is not always the case; for sometimes the scrotum is very much thickened, and the water itself opaque; so that to judge positively if there be a fluid, we must be guided by feeling a fluctuation; and though sometimes it is not very evident, yet we may be sure there is a fluid of some kind, if we are certain that the distension of the tunica vaginalis makes the tumour.

When a gut, or the omentum, form the swelling, it is soft and pliable, unless inflamed, and uneven in the surface, and reaches from the scrotum into the very abdomen; whereas the hydrocele is tense and smooth, and ceases before, or when it arrives at the rings of the abdominal muscles.

When the testicle is increased in size, the tumour is rounder, and, if not attended with an enlargement of the spermatic vessels, the cord may be easily distinguished between the tumour and the abdomen; but without this the pain or the very great hardness will discover it to be a disease of the testicle.

As to the cure, little is to be expected either from inward medicines or outward applications. Therefore it will be most advisable to wait till the tumour becomes troublesome, and then to tap it with a lancet.

Of the JAUNDICE.

THE jaundice is a disease which is principally discovered by the yellow tincture of the skin, but most distinctly in the coats of the eyes, where it gives the first notice of its invasion.

The symptoms are, heaviness, inactivity, lassitude of the whole body, anxiety, uneasiness about the hypochondria, sickness at the stomach, oppression in the breast, difficult respiration, a dry and harsh skin, costiveness, hard white excrements, yellow high-coloured urine, which will tincture linnen or paper with a saffron hue; there is a bitter taste in the mouth; and all objects seem to be discoloured.

The immediate cause of a jaundice is an obstructed excretion of the bile from the vesica felis and liver into the duodenum; which being forced back upon the liver, mixes with the blood, by which it is carried into the whole body, whence the skin and urine will be tinged with the colour of the bile.

This obstruction may be occasioned by any thing in the duct, which plugs up the passage, or by external pressure closes its mouth, or by a spasm contracting the fibres thereof. Hence we may conceive why the jaundice succeeds the flatulent colic, why pregnant women are

re subject to this disease, and why spasms of hypochondriacal and hysterical persons produce the same effect. Sudden frights, the generation of too great plenty of bile, scirrhus tumours or ulcers of the liver, obstructions of the menfes, obstinate intermitting fevers, and the bites of venomous animals, will also produce this disease.

The prognostics of this disease differ with regard to the patient's age, habit, strength, and constitution, as well as with respect to the virulence or mildness of the causes, and its duration. When the patient is young, and the disease not complicated with any other, such as a quartan ague, the affectio hypochondriaca, or an obstruction or scirrhus of the liver, and has not continued long, it is easily cured. But if after the cure it frequently returns, with a yellow greenish colour, and an induration of the liver, it generally terminates in a hectic or an hæmorrhage. A jaundice arising from violent transports of anger, or the spasmodic stricture of the intestines or biliary ducts, caused by a drastic purge or emetic, is easily cured if taken in time; but if encouraged by grief, or the body is weakened by a previous disorder, the cure is more difficult.

Emetics are highly proper in the cure of the jaundice, and yield speedy relief, if the disease does not proceed from violent anger, spasms of the stomach, a cardialgia, a spasmodic colic, or a stone lodged in the cystic duct, exciting a violent uneasiness about the præcordia. But when a bilious fordes, lodged in the duodenum, and closing up the orifice of the ductus choledochus, intercepts the passage of the bile; or when a tenacious, moveable, and not highly concreted bilious matter, plugs up the hepatic ducts, emetics are of singular efficacy in evacuating it. A scruple of ipecacuanha, with a grain of tartar emetic, will be a proper dose; or two grains of tartar emetic, in a draught of generous wine, or in an infusion of manna, drinking water gruel after it.

Likewise in this case, after emetics, cathartics will be proper, compounded of aloetics and mercurials: Then saponaceous attenuants, preparations of tartar, and volatiles.

And here we must recommend the terra foliata tartari, otherwise called tartarum regeneratum, [and by the college, Sal diureticus,] as the greatest dissolvent, and the most powerful remedy in this disease. It dissolves the most tenacious substances, and opens all obstructions of the viscera; and yet has no acrimony, and may be safely given in the pleurisy and dropsy. Its dose is from five grains to a scruple and upwards.

When a jaundice is attended with an hæmorrhage, it is always dangerous, because it denotes a most acrimonious and dissolved state of the blood; in which case, attenuants, aloetics, volatiles, and chalybeates, are little better than poison; whereas acids, diluents, demulcents, and mineral waters, are very beneficial. Hemp-seed, boiled in milk till it breaks, is often advantageous, [the dose is 5 ounces twice a-day,] or an emulsion of white poppy seeds and sweet almonds, after moderate bleeding, (if the patient is feverish, and the pulse will allow it) and gentle purging.

Of the BILIOUS COLIC.

A BILIOUS colic is attended with the following symptoms; a hoarse voice, a cardialgia, a continual loathing of victuals, a vomiting of bilious porraceous matter, hiccup, a feverish heat, inquietude, intense thirst, a bitter taste in the mouth, and the urine little and high coloured. Hoff. Add to these, a burning, acute, continual pain about the region of the navel, which either seems to bind the belly as it were with a girdle, or is contracted into a point as if the patient was bored through, which sometimes remits, and then grows more violent. In the beginning it is not so much determined to one point, nor is the vomiting so frequent, nor does the body so obstinately withstand the force of cathartics. But as the pain increases, the more it is fixed to a point, the vomiting is more frequent, the body more coltive, till at length it terminates in the iliac passion. At this time the pain is so intense as to occasion a singultus, a delirium, coldness in the extremities, and chilling, clammy sweats, which are always a dangerous omen in this disease.

It is distinguished from a fit of the gravel, as the pain in this lies in the kidney, and is extended from thence by the ureter to the testicle; after eating, the colic pain increases, the nephritic abates; evacuations upward or downwards relieve the colic more than a fit of the gravel. The urine in the latter is more clear and thin at first, afterwards there is a sediment, and at length gravel or small stones; whereas in the colic the urine is more thick in the beginning.

Bleed freely in the arm; and after three or four hours exhibit an anodyne, and the next day a gentle cathartic, which may be repeated every other day, to the third time.

Sydenham recommends riding, especially when the cure is only palliated with opiates.

If the disease is caused by a plentiful eating of summer-fruits, the patient should drink posset-drink plentifully, then take an anodyne, and bleed the next day.

Russel observes, that when the colic proceeds from costiveness without a fever, then a pint of sea-water, drank every morning, will cure it. But if the first onset of the disease is neglected, and it proceeds to an inflammation, with a fever, vomiting, and retention of the excrement, and there is reason to be apprehensive of the iliac passion; when black vomiting supervenes, and the fæces are thrown up by the mouth; as also when there is a quick weak pulse, and cold sweats supervene; then the patient will be carried off by a mortification. Sometimes after the rigors, pus will show itself in some place or other, which prevents immediate death; while a purulent tenefusus afflicts the unhappy patient.

Of the HYSTERIC COLIC.

THIS is a common symptom of the hysteric passion, and is attended with a most violent pain about the pit of the stomach, as also with a vomiting of a greenish humour, and a great sinking of the spirits: After a day or two the pain goes off, but upon the slightest motion or perturbation of the mind it soon returns again.

Neither

Neither bleeding nor cathartics have any place in the cure, for they exasperate the distemper; nay, the most gentle clysters are prejudicial: For this disease seems rather to proceed from a disorder of the spirits, than from a fault of the humours. It will be proper first to advise the patient to drink upwards of a gallon of posset drink, to clear the stomach of its impurities, by throwing it up again, that the effects of the purgative may not be hindered. Afterwards give 25 drops of the thebaic tincture, in an ounce of cinnamon-water. This last is to be repeated at due intervals, till the symptoms disappear; that is, the effect of one dose must be known, before another is given. Yet sometimes, in plethoric bodies, if the strength will permit, it is better to prepare the way, by bleeding and purging, or both, for an anodyne.

Of the FLATULENT or WIND COLIC.

If there is a fixed and tense pain in the right or left hypocondrium, or beneath the stomach, it is a certain sign that there is wind or excrements pent up in the flexures of the colon. If the pain is in the small guts, the abdomen will be wonderfully swelled and puffed up; and the force of the wind is often so great, and it distends the skin to such a degree, that the pain is exasperated merely by touching it; nor do there want instances of a navel-rupture arising therefrom. The pains are very acute, the body extremely colicive, there is a sense of a very great straightness or contraction; and if the stomach is inflated, the breathing becomes very difficult, and the eruptions are attended with some small relief. Afterwards there are cardialgic passions, and an ineffectual reaching to vomit.

If the disorder lies in the flexures of the colon, emollient and discutient clysters will be proper, as also carminative and emollient liniments applied to the pained part.

When the body is opened, it will be beneficial to give some lenient purge, as manna, cream of tartar, terra foliata tartari, with a spoonful or two of oil of sweet almonds.

While the pain is violent, the infusion of chamomile flowers and yarrow, in the manner of tea, frequently drank, is a very powerful remedy.

It will be also beneficial to apply hot bricks or tiles to the part affected; also bags with parched oats and carminative ingredients, as carraway seed, juniper and bay berries, with decapitated salt. A clyster of the smoak of tobacco, blown through a pipe into the anus, is reckoned an excellent thing.

When indurated faeces plug up the intestinum rectum, so that the wind and feyals can make no exit, then the anus is to be fomented with emollient decoctions; and saline suppositories, with fat, are to be used; also some ounces of linseed oil, with an emollient decoction in which venise soap has been dissolved, are to be injected as a clyster.

Of the COLIC from Fumes of Lead.

This is a disease to which all workers in lead are subject; and is attended with an intolerable pain in the intestines, and a most colicive body: the navel is drawn in-

ward, there is the highest inquietude and a contraction of the joints, attended with a nausea, and a constant reaching to vomit. It is apt to terminate in a kind of palsy, or a spasmodic asthma, and afflicts the patient a long time. It is sometimes owing to the rashness of medicalists, in giving preparations of lead in the gonorrhœa and other distempers.

There is no better preservative against this disease, than by taking fat broth in a morning; the cure is to be attempted with oleous clysters, and a plentiful use of oil of sweet almonds taken by the mouth, with or without a solution of manna, by which the desired end will generally be obtained. For the cure for the paresis, baths of sweet water are necessary; after which the spine of the back must be anointed with a liniment made of the fat of a hog, expressed oil of nutmegs, saffron, and oil of rosemary, which is a speedy and a certain remedy.

This disease is called mill reek by the miners at lead-hills in Scotland, which all the inhabitants there are subject to; but melters of lead have it with the greatest violence.

In the slighter stage of it, there is an uneasiness and weight about the stomach, particularly near the cartilago eniformis, and sometimes it is like a colic in the intestines. The spirit of the patient is sweet, and inclining to a bluish colour, resembling that of a person who chews lead. The pulse is lowish, and the skin is all over cold, with frequent clammy sweats. The legs become feeble, with a pricking numbness; and the whole body is lazy and feeble. Sometimes a spontaneous diarrhœa carries off the disease; but if it continues long, it is very prejudicial. During this stage the patient is able to work.

When these symptoms continue long, and spirituous liquors are drunk on an empty stomach, or after the working of lead, the second stage comes on; and then there is a fixed pain in the stomach and guts, especially in the lower part of the belly, extending from one hip-bone to the other, with coliciveness and a gnawing pain. The pulse then becomes weak, and the skin hot. There is likewise a giddiness and a violent pain in the head, which is succeeded by an insensibility and a delirium of the worst kind; for they bite their hands and tear their own flesh. Then their extremities tremble with convulsions; and at length they sink with an intermitting pulse, and die of a coma or apoplexy.

If proper medicines are given in the first stage of the disease the patient generally recovers. If it proceeds till the giddiness comes on, the success is doubtful; but after that it almost always proves mortal.

Workers in lead should never go to their business fasting, and their food ought to be oily or fat. A glass of salad oil, with a little brandy, rum, or other spirit, is a good morning's draught; but spirits alone should never be taken while at work, nor immediately after it. Physick should be taken spring and fall, and no man should go into the cold air while hot with labour, and they should change their working-cloaths for others as soon as possible. Liquid aliment is best, such as fat broth with good meat; for low living is bad. They should now and then go a little way out of the tainted air.

If the patient is plethoric, the cure is to be begun with
 † E f † bleeding,

bleeding, and then the *prima via* must be cleansed with a double dose of emetic wine, or emetic tartar, otherwise it will have no effect. They will even bear half a dram of glass of antimony in fine powder, with plenty of warm water during the operation. If the vomit works well upwards and downwards, the patient is in a fair way of recovery. Then a milder dose of ipecacuanha must be given with tartar emetic. If the dose does not work either way, he is generally the worse for it, and a stronger dose should be given soon after. If it vomits, but does not purge, an antimonial cathartic, or jalap and mercury should be exhibited in a larger quantity than ordinary, and then the patient should drink plentifully of warm broth. The vomits and purges should be repeated at proper intervals till the disease disappears. If they work too much, an opiate may be given at night, but with caution, for fear of rendering the patient colicive, which is the worst thing that can befall him. When purgatives do not operate sufficiently, emollient, laxative, and anodyne clysters must be injected frequently to empty the guts.

Of the ILIAC PASSION.

THE iliac passion is a pain in the small intestines, apt to turn to an inflammation, in which their peristaltic motion is inverted, and their contents, and even the excrements themselves, are voided by the mouth in vomiting. Nothing will pass downward, not so much as a flatus.

It is preceded with costiveness, which is soon followed with most sharp and violent pains, with an inflammation, distension, and a tumour of the umbilical region, which feels hard to the touch; the body is so bound, that neither wind nor excrements can pass downward: Soon after, the wind first makes its way upward, then comes on a nausea and a frequent vomiting of a bilious and pituitous matter: The breathing grows difficult, and whatever is eat or drank is soon thrown up again; reddish sœces, with a stinking smell, are afterwards forced up by vomiting: This is succeeded by loss of strength, a preternatural heat, a hard and contracted pulse, with great thirst; the urine is red, and voided with difficulty. When the case becomes desperate, a hiccup and delirium appear; the nerves are distended, the body is all in a cold sweat, and violent convulsions and fainting fits put an end to the tragedy.

In some who have been affected, the gut seemed to be twisted; but most commonly one part of the gut enters into the other. This disease may also proceed from a rupture either of the scrotum or the groin; from poisons; from any thing that stops up the passage through the small guts, such as hard dry food, quinces, pears, unripe acer fruit, when eaten in large quantities; to which drinking little, a sedentary life, and a melancholy disposition of mind, will greatly contribute. These all tend to harden the feces. The gross intestines may also be plugged up with scybals; especially if a person, either through shame, or for want of conveniency, does not listen to the calls of nature.

As to the prognostics; there is hope of recovery while there is no inflammation, and while clysters are admitted

into the body, and rendered back the same way; as also while the pain shifts from one place to another, and the pain and vomiting are not continual; likewise when the disease proceeds from feces obstructing the intestines. The hope is still greater, if laxative medicines begin to make their way downward. But if there is an inflammation, which is known from a fever, the vehemence of the pain, a suppression of urine, a hard and quick pulse, an unquenchable thirst, a tossing of the body, and extreme debility, with coldness of the extreme parts, the case is desperate. A sudden cessation of pain, and absolute want of strength, with a weak pulse, fainting fits, and a sinking breath, shew the intestines are mortified.

As to the cure; first of all it is necessary to bleed in the arm, and afterwards, in an hour or two, exhibit a powerful clyster. The smoke of tobacco blown into the bowels through an inverted pipe, is very efficacious: This may be repeated after some time, unless the effect of the first renders it unnecessary. If the disease will not yield to this, a pretty strong cathartic is advisable.

If the patient cannot retain the cathartic, let him take 25 drops of the thebaic tincture in half an ounce of spiritous cinnamon water; and when the vomiting and pain remit, let the cathartic be repeated; if the pain returns, give the anodyne again, and repeat it every fourth or sixth hour till the intestines are easy, and the cathartic begins to pass downwards.

After the pain has been mitigated with anodynes, a cataplasm should be applied to the hypogastric region to stop the vomiting and hiccup; which may be composed of equal parts of old venice treacle and expressed oil of nutmegs, with the addition of oil of mint and camphor. This done, a gentle laxative of manna, cream of tartar, and oil of sweet almonds, may be given.

When there is an inflammation, nothing is better than six or eight grains of purified nitre, and half a grain of camphor mixed with some antispasmodic powder, and taken in a convenient vehicle. Outwardly apply a liniment of an ounce of axungia humana, [any other penetrating fat will do as well] and a dram of camphor.

But when other things fail in the cure of the iliac passion, recourse must be had to quicksilver, which sometimes has surprising effects; half a pound, or a pound at most, is sufficient, with fat broth or oil; and the patient should lie on his right side, or walk gently about the room, that its descent may be easier. But if there is an actual inflammation, the use of quicksilver should be forbore; if the patient dies, from what cause soever, the bystanders will probably affirm the quicksilver killed him.

There is no manner of danger in the use of opiates, to mitigate the pain, provided they are exhibited in the beginning, after bleeding, or before there are any signs of a mortification.

Clysters are generally very advantageous; for they relax the spasms of the gro's intestines: and for this purpose warm water with syrup of marshmallows will be sufficient; and if the strength will permit, they should be injected every two hours, from the first day of the attack. They likewise restrain the inversion of the peristaltic motion, and soften the sœces.

OF VOMITING.

Vomiting is a spasmodic, retrograde motion of the muscular fibres of the œsophagus, stomach and intestines, together with strong convulsions of the abdominal muscles and diaphragm. Those that are slight, create nausea; those that are strong, vomiting.

Vomiting generally begins with a nausea, a tension and weight in the epigastric region, a bitterness in the mouth, anxieties of the præcordia, plenty of thin saliva in the mouth, a trembling of the neither lip; to these may be added, a dizziness of the head, a sudden dimness of sight, redness of the face, a fruitless eructation; and then the contents of the stomach are discharged upwards.

Vomiting is caused by excesses in eating and drinking; by the acrimony of the aliments; by the translation of the morbid matter of ulcers, the gout, erysipelas, and other diseases, to the stomach; from a looseness or bloody flux too suddenly stopped; from a congelion of blood in the stomach, which happens to women in the first months of pregnancy, or when there is a suppression of the menses, or bleeding piles; from sympathy, by tickling or irritating the throat or œsophagus with the finger or a feather: from the colic, iliac passion, a rupture, fit of the gravel, worms; from poisons; from hurts of the brain, such as contusions, compressions, wounds or inflammations of the diaphragm, stomach, intestines, spleen, liver, kidneys, pancreas or mesentery: from an unusual motion of the spirits in a cart, coach, or ship; from the idea of some nauseous thing, or which has formerly occasioned sickness or vomiting; from a regurgitation of bile into the stomach.

As to the prognostics; a critical vomiting is salutary; a symptomatic bad; and that which proceeds from a subtil caustic acrimony, which vellicates the nerves, worst of all. All violent excessive vomiting is bad, as it may occasion abortions, ruptures, &c. Bilius vomiting, especially the green, porraceous, and æruginous, consisting of a corroding acid, portends danger of an inflammation; vomiting from worms which gnaw the stomach, is generally pernicious; vomiting of dead worms, if at the same time the convulsions of the limbs and other grievous symptoms suddenly cease, shews a mortification. All ætoid vomiting is a sign of internal corruption, and therefore bad.

When vomiting proceeds from crapula, late suppers, disturbed digestion by riding, and the like, it may be prevented by deep inspirations often repeated, by which the diaphragm is made to press on the stomach, and accelerate the discharge of it contents; but if an inclination to vomit, from the same causes, comes on unawares, a pretty strong and often repeated friction of the hypogastric region with the hand, will prevent it.

Prituitous vomiting, from crudities of the primæ viæ, is best cured by a vomit, and especially if there is a troublesome reaching to vomit: attended with a nausea and a cardialgia; then having first prescribed neutral salts, or squills, to incite the phlegm, give warm water mixed with unsalted butter, very plentifully, or powder of ipecacuanha.

Bilius vomiting, which proceeds from a depraved digestion, and has its seat in the duodænum, is cured by

absorbents and gentle laxatives of manna and rhubarb. When it proceeds from too great a laxity of the biliary ducts, then cortex Peruvianus, cortex eleutherizæ, and bitter tinctures and chalybeates, will be most efficacious; if from a coagulum or stone in the gall bladder, mineral waters are more likely to succeed.

When vomiting is caused by a sharp matter vellicating the nerves of the stomach, proceeding from the gout, or an erysipelas, besides giving quieting medicines, it ought to be drove back by diaphoretic powders, with a small addition of camphor. Also externally, frictions, pediluvia, and clysters, are useful.

When it proceeds from poisons, nothing is better at the beginning than drinking large quantities of milk, and fat oily things, to sheath their acrimony, and bring them up by vomiting.

Vomiting from a suppression of the menses, or from the stoppage of the bleeding piles, is cured by absorbents, by gentle laxatives, by clysters and strengtheners; and more especially by bleeding or causing the flux to return. Emetics, in this case, are as bad as poison, and either cause a vomiting of blood, or a fatal inflammation of the stomach.

Morning reachings, caused by hard drinking, are cured by absorbents and anti acids, and by strengthening the digestive faculty, by bitters, candied orange-peel, &c.

The immoderate and frequent vomiting of pregnant women requires bleeding in the foot, and rest both of mind and body.

Of the Vomiting of Blood.

VOMITING of blood is generally preceded with a tense pricking pain in the left hypochondrium; and the eruption itself is almost always attended with anxiety of the præcordia, and a compressing pain, as also a kind of girding on the same side. It is frequently attended with fainting fits, especially if the blood has an ill smell, or is corrupted.

The seat of this disease is in the stomach, though the spleen sometimes has a share in its production.

Persons more subject to it are the lean and slender; women irregular in their menses, and who have been hastily cured of intermitting fevers, which has brought on a suppression of the menses, and then have taken hot forcing emmenagogues; as also women about the time their menses leave them; likewise plethoric women in the time of pregnancy, and hard labour; and men of a weak constitution, subject to the bleeding piles, which either cease to flow, or flow in too small a quantity.

The danger which attends this disease, is not the same in all, though no hæmorrhage is more dangerous than this. If there is no fever, and if it proceeds from suppressed evacuations, caused by a plethora, the case is not so desperate. On the contrary, if there is a fever; if the blood is corrupted, stinking, and black; if it proceeds from a large, diseased spleen, or an indurated liver, attended with swooning; there is no hope of recovery left. It is still worse, when the stools are black; then the seat of the disease is in the ileum, from a rupture of the mesaric vessels.

In the paroxysm, if the patient is plethoric, bleed according to his age and strength.

When

When there is an orgasm in the blood, and the pulse is impetuous and strong,

Take a pound of water, a dram of nitre, and half an ounce of syrup of wild poppies.

This, taken successively and temperately, will be very efficacious in perfecting a cure.

When the region of the præcordia, especially on the left side, is afflicted with pricking and vellicating pains, and spasmodic strictures, together with heat and thirst, emulsions will be proper. These must be made with the four cold seeds, and white poppy seed; to which must be added a little nitre, and a proper quantity of diacodium.

Likewise, in order to relax the spasmodic strictures of the intestines, and to divert the flux of the humours from the part affected, emollient clysters, frequently injected, will be proper, with a gentle stimulus, and the addition of nitre.

Outwardly, to relax the spasms and strengthen the stomach, nothing is better than the oil of camphor; which is made by dissolving a dram of camphor in an ounce of oil of sweet almonds, and then by adding twenty drops of oil of rhodium. Let the region of the præcordia and the left hypochondrium be anointed with this oil; and afterwards lay a bag on the part affected, filled with camomile and elder-flowers, with mint and wormwood, boiled in vinegar of roses or red wine pretty hot.

If blood is thrown up in great quantity, with loss of strength, ligatures made upon the joints may be serviceable, as also putting the legs and arms in cold water.

When the paroxysm is off, half a dram of rhubarb will be highly beneficial, either with or without testaceous powders; or twelve grains of compound powder of amber, with half a grain of camphor taken twice a-week, at night going to bed, in a draught of spring water. Rhubarb is a kind of a specific in opening obstructions. The patient, instead of tea, may drink a decoction of yarrow, liquorice, and fennel seeds. The common drink may be spring water, in which iron has been quenched, or acidulated whey.

If this disease proceeds from a suppression of the menfes; bleed in the foot, and give clysters prepared of mugwort, pennyroyal, wall-flowers, bay and juniper-berries, pretty frequently.

If it is caused by sharp acid liquors corroding the vessels of the stomach, then testaceous alkaline powders are proper; and starch boiled in milk will heal the vessels.

Opiates must be shunned in these cases, because they bring on great weakness and loss of strength, to the great detriment of the patient. Likewise all styptics, astringents, and vitriolic medicines, must be studiously avoided; these, indeed, will stop the eruption of blood; but then it will stagnate and putrify in the vessels, with danger of an inflammation and mortification; or at least, if the patient is cachectic, it will hasten a dropsy.

Of a DIARRHŒA, or LOOSENESS.

A DIARRHŒA is a frequent and copious evacua-

tion of liquid excrements by stool; and may proceed from aliments, or humours of various kinds, derived from different parts into the intestines.

The cause is a stimulus which irritates the viscera, occasioning the expulsion of their fluids; and may therefore proceed from the vessels of the liver, pancreas, mesentery, and intestines; when at the same time the mouths of the mesenteric veins and the lacteals are obstructed. Or there may be an extraordinary laxity of the intestinal fibres; or, lastly it may arise from a stoppage of other excretions. It is frequently attended with gripings. The patient is weak, makes but little urine, has a depressed pulse, a depraved appetite, and is sometimes feverish.

In a diarrhœa arising from sharp fermenting juices in the *prima via*, which accelerate the peristaltic motion of the intestines, the first indication is to discharge the stimulating matter; which may be effected by a dose or two of rhubarb.

At night the patient may take fifteen drops of the thebaic tincture, in two or three spoonfuls of simple cinnamon water. The rhubarb is to be repeated till the looseness abates, which is generally after the second dose.

If there is a saburra of ill-cooked matter in the stomach, a vomit will be necessary of ipecacuanha, [or an ounce of its wine.]

If the diarrhœa continues to be violent, it will be proper to mix astringents with the rhubarb.

If the diarrhœa proceeds from suppressed perspiration; and if the stools are thin, and the patient feverish; first bleed, then give an emetic, afterwards a purge of rhubarb. and half of all astringents.

But the best and safest astringent of all is logwood, given in decoction.

A bilious diarrhœa ought not to be too suddenly stopped, but the humours are to be corrected gradually; for which purpose, a scruple of rhubarb slightly toasted, with a few grains of nitre, is very useful. Likewise half a dram of the expressed oil of nutmegs, either alone or mixed with a grain of opium, and given in broth, is very efficacious. The humours are likewise corrected with thin emulsions of almonds and white poppy-seeds, with the addition of diacodium.

When a diarrhœa is very obstinate, after toasted rhubarb has been given for some days, prescribe a treat with a dram of new venice treacle, and twelve grains of burnt hartshorn, calx antimon. and purified nitre.

An habitual diarrhœa is greatly relieved by wearing a flannel shirt, and keeping the body warm.

In Vol. I. of the *London Medical Observations and Inquiries*, Dr Pye proves, by a long enumeration of instances, that in all loosenesses where emetics are advisable in every age and sex, though the patient be in the weakest circumstances, ipecacuanha, from half a grain, to four or six grains, may be given with the utmost safety, and will seldom fail of answering the intention of the prescriber; and adds, that for many years he had experienced the great efficacy of it, in curing or assisting in the cure of diarrhœas in children, when administered in clysters.

*Of the CHOLERA MORBUS, or Vomiting and
Looseness.*

A CHOLERA, or vomiting and looseness, is a sudden violent purging upwards and downwards, proceeding from a convulsive contraction of the stomach and intestines, caused by sharp caustic matter of various kinds.

It generally begins in August, and seldom reaches the first weeks of September, unless it be a spurious kind which arises from excess.

It discovers itself by enormous vomiting, and a voiding of vitiated humours by stool. There is a violent pain, inflation and distention of the belly and intestines, as also a cardialgia and thirst; the pulse is quick and frequent, small and unequal; there are heat and anxiety, a most troublesome nausea, sweating, a contraction of the legs and arms, fainting, coldness of the extreme parts, and the like, which kill the patient in twenty four hours.

Though this disease is generally preceded with acid, nidorous belchings, pungent and cardialgic pains in the stomach and intestines; yet soon after, all of a sudden, and at the same instant, the vomiting and looseness make their attack. The remains of the last meal are voided first: afterwards bilious humours, mixed more or less with mucus; then those that are yellow, then eruginous, then black, often exceeding acid, and almost corrosive, together with frequent eructations and wind, and sometimes blood itself. The returns of the evacuations are very frequent. Besides, there are most acute, wringing, gripping, gnawing, biting pains, with inflation and rumbling of the intestines, chiefly above the navel, and most racking cardialgias. As the disease increases, the thirst becomes great, the extreme parts grow cold: there is a palpitation of the heart, and then hiccups; the urine stops, and the body is covered with a cold sweat. It is common for the patient to swoon away, and to fall into terrible convulsions.

There is no disease, except the plague and pestilential fevers, that kills sooner than this, especially if it attacks old persons, or children, or such as are weakened with diseases. The more caustic the matter is which is voided, the more intense are the thirst and heat, and the more certain the danger. If it be black bile, and mixed with black blood, death is inevitable. The case is as bad when there are faintings, hiccups, convulsions, coldness of the extreme parts, and cold sweats. Nor is any thing better to be expected from a stoppage of the evacuations, while the rest of the symptoms continue. But if the vomiting ceases, and the patient sleeps soon after, or the disease is protracted beyond the seventh day, he may recover; if he begins to break wind downward, it is a good sign.

This disease requires the most speedy assistance, and therefore the physician cannot be called too soon. The indications of cure are, 1. To correct and sheath the morbid matter, and to fit it for evacuation. 2. To appease the irregular spasmodic motions. 3. To strengthen the nervous parts which the disease has weakened.

Boil a large chicken in three gallons of water, that so there may be scarce any taste of the flesh and give the patient a large quantity of it to drink; or, for want of it,

warm posset-drink; and also repeated clysters of the same liquor; now and then an ounce of syrup of violets may be added to the draught or clyster. These operations may be completed in three or four hours, and then a pargoric will crown the whole.

But if the physician is not called in time, and the patient has been exhausted with vomiting and purging for many hours, and the extreme parts begin to grow cold, then immediate recourse must be had to liquid laudanum in a large dose. And when the symptoms cease, it is to be repeated morning and evening, till the patient's strength returns.

Neither cathartics nor emetics, properly speaking, are of use in this disease; but the vomiting may be promoted by drinking a large quantity of warm water mixed with fresh butter or oil; and the purging by oily and emollient clysters. Or the patient may drink small chicken-broth. Why is of great use to quench the thirst; to which may be added, the absorbent and testaceous powders.

If the patient is not too much exhausted, make him drink plentifully of warm water three or four times, to dilute and blunt the acrimony of the humours, and to bring them up by vomit: Then he must take as freely of a decoction of oat bread, baked without leaven or yeast, carefully toasted, without burning, as brown as coffee; which decoction ought to be of the colour of weak coffee. This is grateful to the stomach, and is seldom brought up again.

When the patient is much exhausted with evacuations upwards and downwards, give him a large draught of the decoction; and, when the nausea is pretty well settled, two thirds of a grain of opium, more or less, according to the strength and age of the patient.

But if the patient is convulsed, the extreme parts cold, and the pulse weak and intermitting, twenty-five drops of liquid laudanum, in an ounce of strong cinnamon water, is more proper: and afterwards a draught of any wine in an equal quantity of the decoction. After this, he may take the decoction to quench his thirst, and a little wine now and then as a cordial.

To prevent a relapse, repeat the opiate in a moderate quantity for some days, morning and evening; and care must be taken not to overload the stomach, or to eat any thing but what is of good nourishment, easy to digest, and grateful to the stomach.

Of the DYSENTERY, or BLOODY-FLUX.

A DYSENTERY begins with shivering and shaking, succeeded by heat of the whole body; which are followed by griping of the guts, and soon after by frequent voiding of slimy stools, attended with violent pain, and a most troublesome pressing down or seeming descent of all the bowels, and this every time the patient has a stool. In process of time the stools are mixt with blood, and afterwards pure blood is only evacuated, and the intestines are afflicted with an incurable gangrene. Yet sometimes there has been no blood through the whole progress of the disease.

If the patient is in the flower of his age, or has been heated with cordials, he is very feverish, his tongue is

G g † whitish,

whitish, and beset with a thick mucus; sometimes it is black and dry; he becomes excessively weak, and is quite destitute of spirits; aphthæ or a thrush appear in his mouth and throat, especially if the evacuation of the morbid matter has been preposterously prevented by altringents, and the fumes of the disease has not been expelled by cathartics. Sometimes, when a fever is absent, the gripes lead the van, and the rest of the symptoms follow.

Those whose stomachs are loaded with much indigestible matter, are troubled with a nausea, reachings and vomiting; many have an intolerable heartburn and anxiety of the præcordia. All are afflicted with a perpetual desire of going to stool, and such a violent tenesmus as is not seldom attended with a proclitica ani.

In some, the extreme parts are cold, while the inward seem to burn, and a perpetual sense of heat and a pulsation torture the intestines. To these succeed hiccups, cold sweats, a pale countenance, waiting of the body, inflammations, and aphthæ of the fauces. At last, all pain ceases at once, the thirst vanishes, the stools come away insensibly with a cadaverous stench, the pulse becomes slender, and death is at hand. This disease is often contagious.

Prognostics. Dysenteries are dangerous to pregnant women, to old men, and to boys. There is commonly little hope when it attacks the scorbutic, the consumptive, and the cachectic; those that are weak and afflicted in mind, or troubled with worms. When it begins with vomiting, succeeded with hiccups, there is danger of an inflammation of the stomach. Nor is the case better when the stools are green, black, mixed with caruncles, and of a noisome stench. It is a fatal omen when clysters are immediately returned, or the anus so obstinately closed that nothing can be injected; for it is a sign of a palsy of the rectum. When the pulse is weak, the extreme parts cold, and the inward burn, or are without sense, nothing good can be expected. When swallowing is attended with a murmuring noise, it shews the approach of a delirium, an inflammation of the fauces, aphthæ, or a palsy of the whole œsophagus. It is necessary to know, that this disease sometimes quickly terminates, especially if there be a malignant fever, and then it kills in seven, nine, or fourteen days; sometimes it does not cease till the fortieth or upwards; when it continues a long while, it either kills the patient, or brings on a dropsy, a lientery, the cœliac passion, a tabes or hectic, which are incurable.

The common method of curing a dysentery, is first to bleed, then to vomit with ipecacuanha, afterwards to purge with rhubarb, and last of all to give altringents. Hoffman directs a scruple or half a dram of the ipecacuanha, with a terebinthaceous powder, drinking a large quantity of warm water after it. This vomit is sometimes to be repeated. It is the modern practice, after the first vomit, to give two or three grains of ipecacuanha every eight or ten hours, in a bolus, with dialcordium, or the like, with some proper julep. Hoffman would have the rhubarb given in substance, that is, half a dram in powder; Dener gives it twelve hours after the vomit, repeating it in small doses.

Mr Ray says, that the fungous substance between the

lobes of a walnut, dried and powdered, and given in a moderate quantity in wine, cured the English army of a terrible dysentery in Ireland, when all other remedies failed.

Julcius says, a thick yellow bark, called simaruba, has been found successful in the cure of a dysentery. The dose is a third part of a quart of a decoction made with two drams of the bark. And Cramer assures us, we may depend upon the same effect from the decoction of common millet-seed, called St Ambrose's syrup, which Luther looked upon as a cure for the colic. Count Argenton took it first by his advice, merely to quench his thirst, in the manner of tea, by which means he got rid of his thirst and dysentery in twelve hours time.

Another specific is the vitrium antimonii ceratum, which has been in use for some time, but was kept a secret till it was communicated by Dr Young of Edinburgh to the public.

The manner of preparing it is as follows:

Take of glass of antimony in powder, one ounce; bees-wax, one dram: melt the wax in an iron ladle, then add the powder: set them on a slow fire without flame, for the space of half an hour, continually stirring them with a spatula; then take it from the fire; pour it upon a piece of clean white paper, powder it, and keep it for use.

The ordinary dose for an adult is ten or twelve grains; but for greater safety begin with six.

Never give opiates in the beginning, especially where there is great sickness; because, though opiates give relief to some, yet at other times both the sickness and purging increase the following day.

Bontius, in his account of the diseases of the East-Indies, affirms, that extract of saffron is a specific in the dysentery of those parts, even though it should proceed from poison.

Of the HEAD-ACH.

THE head-ach is a most troublesome sensation in the nervous membranes of the head, produced by various causes, and attended with different symptoms, according to its different degrees, and the place where it is seated.

The most common seat of this disease is the pericranium; a membrane which invests the skull, coheres with the muscles next the skull, and is joined to the dura mater by some fibres which pass through the sutures. It is a thin nervous membrane of exquisite sense. It may likewise be in the skin that covers the skull, and in the dura matter. This last but seldom happens; but when it does, it is very dangerous. There may likewise be a very acute pain in the thin membrane which covers the sinus of the os frontis.

If the head-ach be slight, and affects a particular part of the head, it is called cephalalgia; if the whole, cephalæa; if one side only, hemicrania; if there is a fixed pain on the forehead, which may be covered with the end of the thumb, it is called clavus hyftericus.

The general cause of the head-ach is a hindrance of the free circulation of the blood through the vessels of the head.

When

When the blood rushes with impetuosity, and in too great plenty into the membranes, which may happen to the plethoric, to those whose usual bleeding at the nose is suppressed, and to young persons, there is a pain in the whole head, which becomes hot, swells, aches, and looks red; the vessels swell, and there is a strong pulsation in those of the neck and temples. The nostrils are dry and parched, there is a burning heat and drought in the fauces.

When the vessels of the head are stuffed with a mucous serum from a stoppage of the running of the nose, then there is a heavy, obtuse, pressing pain, chiefly in the forehead of the head, in which there seems to be such a weight, that the patient can scarce hold it up. Sometimes the skin is so swelled, that it will pit.

Sometimes it happens from the serous, sharp, caustic matter of the French disease, which infects the pericranium, and often causes a caries in the skull.

Sometimes it may proceed from matter of a saline caustic nature, driven back from the external parts; as, in the gout, itch, erysipelas of the head, gutta serena; in the small-pox and measles, before the morbid matter is expelled to the outward skin, or, which is worse, when it is driven back. In these cases, when a small quantity of caustic matter causes the pain, it rather proceeds from a violent stricture of the membranes than from their distension.

There is likewise a most violent, fixed, constant, and almost intolerable head-ach, which brings on a debility both of body and mind, hinders sleep, disturbs digestion, destroys the appetite, causes a vertigo, dimness of sight, blindness, a noise in the ears, convulsions, and the epilepsy; and, by consent of the other nervous parts of the body, produces vomiting, costiveness, coldness of the extreme parts, and the countenance of a dying person.

Sometimes the head-ach is symptomatic, and attends upon continual and intermitting fevers, and especially the quartan, irregular flowing of the menses, the hypochondriac passion, and the like. A hemicrania generally proceeds from a fault in the stomach, from crudities or indigestion, and commonly appears when digestion is performed.

The head-ach is not always without danger: If the cause of the pain is within the skull, and is violent and constant, attended with a fever and want of sleep, it portends a phrensy. If it suddenly attacks the hypochondriac, or those that are prone to melancholy, especially if preceded by a violent passion of the mind, and deprives the patient of sleep and appetite, and is joined to difficulty of hearing, and an internal pulsation of the vessels, and all these without a fever, it presages madness. But when the pain in the head is sudden and very acute, with a noise in the ears, difficult walking, a weakness of the knees, an impediment and slowness in speech, it is the forerunner of an apoplexy or a palsy; in which last the pain is greater on the well side than the diseased, because the latter has lost all sensation.

The curative indications are, 1. To divert the impetus of the blood and humours from the head, and to discuss them by suitable remedies. 2. To relax the spastic strictures of the membranes of the head, the cause of

which is a sharp caustic matter, that the fluids may have a freer circulation. 3. To correct the peccant matter, and evacuate it gently through the most convenient emunctories. 4. To prevent a return by strengthening the whole nervous system by proper remedies, and especially by an accurate diet and a suitable regimen.

When the blood rushes to the head in too great quantity, bleeding is necessary; more particularly under the tongue, in the forehead, in the jugulars, or by leeches behind the ears. If the body abounds with too much blood, it will be best to bleed in the ankle first, and the next day, or the day after, in a vein about the head. But first of all cleanse the body by any emollient clyster, or by giving an infusion of rhubarb and manna, with cream of tartar.

To restrain the orgasm of the blood, it will be proper to give a diaphoretic and absorbent mixture, with diaphoretic antimony, purified nitre, burnt hartshorn, and diacodium, diluted with a sufficient quantity of suitable simple distilled waters.

When there is an intense pain remaining fixed in one place, lying pretty deep in the membranes, the herb ranunculus, used as a vesicatory, has a wonderful efficacy. It is the upright meadow-crawfoot, with leaves like the anemone, and, if tasted, is extremely biting to the tongue. The leaves must be bruised in a marble mortar, and the part, if hairy, shaved; then a sticking plaster is to be laid on it, with a hole about the bigness of a silver penny, and the leaves over that; just in the same manner as a caustic. This is an experiment of Chesneau's; and like success may be had by mixing equal parts of volatile sal ammoniac and powder of mustard-seed, laying it on the part in the same manner.

When it is caused by a suppression of a coryza or running of the nose, a smelling-bottle of volatile salts should be held frequently thereto. Or the patient may take herb-snuff, with the addition made of flowers of benjamin and powder of cloves.

When the head-ach arises from a corrupted mass of blood and an impure serum, as in the scurvy and lues venerea; a decoction of the woods with crude antimony may be serviceable, after evacuations, fasting a day now and then, with labour and exercise, will likewise be useful; as also a sudorific.

A hemicrania, especially a periodical one, is generally owing to a fullness in the stomach and *prima via*; for which gentle emetics will be beneficial, as also purgatives to derive the humours from the head; afterwards stomachics. If it proceeds from profuse evacuations of the menses or hæmorrhoids, those fluxes must be reduced within bounds.

If the head ach is so intolerable as to endanger the patient's life, or is attended with continual watching, fainting fits, a fever, an inflammation, or a delirium, recourse must be immediately had to opiates with native cinnaabar, after a clyster has been first given.

When there is an intolerable pain in the sinuses of the nose, or the bony sinuses of the head, produced by an extravasation of some fluid, the only cure is scarification of the nostrils, or causing the nose to bleed with a straw suddenly thrust therein.

If there is an extravasation under the pericranium, and the humour is so sharp as to begin to render the bone carious, then recourse must be had to an incision, as in a whitlow.

In some kinds of head-ach, it will be proper to open the frontal vein.

When the patient's strength will not bear the loss of blood, temperate pediluvia will be beneficial, and strong frictions of the feet with a coarse cloth; as also cataplasms of horse-radish and salt laid thereto.

Of the HEART-BURN,

THE heart-burn is a pain more or less violent about the pit of the stomach, with anxiety, a nausea, and often a reaching, or actual vomiting.

The causes are, vitiated humours in the stomach, velli-cating and gnawing the stomach itself, or its left orifice, which the ancients call cardia. The stomach thus irritated, a painful sensation is excited, and spasmodic constrictions, which occasion a nausea and vomiting. But common heart-burns are generally without vomiting. The heart-burn may also proceed from wind and indigestion, and now and then from worms; but more frequently from congestions of blood about the stomach, which may happen to those who are full of blood, but more especially to the hypochondriac and hysteric, when vomiting of blood not seldom ensues.

The cure of a common heart-burn from indigestion and the acrimony of the contents of the stomach, which chiefly happens in a morning with wind, may be performed only by drinking tea or coffee, or a decoction of camomile flowers; as also by taking bitters, or a dram of powder of orange-peel, or camomile flowers, in a small glass of wine made pretty hot, and sweetened with sugar. The testaceous and absorbent powders are excellent in this case; such as the tabellæ cardialgicæ, or lozenges for the heart-burn, which may be carried in the pocket and taken at pleasure; about a dram is sufficient for a dose.

When it arises from a crapula, gentle emetics will be useful. If the patient begins to vomit without them, large draughts of warm water will assist to cleanse the stomach; or carduus benedictus tea taken freely.

If the cardialgia proceeds from a congestion of blood, and the painful spasms then arising, bleeding will be convenient, and emetics hurtful. If the menses are stopped, bleed in the foot.

Nor must anodyne and emollient clysters be omitted. It will likewise be proper to apply a bladder filled with a decoction of chamomile, pretty hot, to the stomach. After recovery, riding will be convenient to regain the lost strength.

If worms are the cause of the heart-burn, no acrid anthelmintics must be given, but warm milk mixed with oil of sweet almonds, which, if drank in sufficient quantity, may cause them to be thrown up.

Of the TOOTH-ACH.

THE tooth-ach is caused by impure serum, which corrodes and rends the ligaments and nerveo-glandulous

coats, by which the roots of the teeth are kept firm in their sockets, and wherewith they are invested.

It is a kind of rheumatic disorder; for we have often observed that pains of the joints and shoulders have shifted to the side of the head, and have invaded the teeth and gums with violent pain. On the contrary, pains of the head and teeth have fallen into the arms and shoulders.

The seat of the tooth-ach may also be in the cavity or internal parts of the teeth themselves, that is, in the little vesicular cord composed of the nervous membrane, an artery, a vein, and a lymphatic vessel, which may either be distended by stagnating serum, or be affected with a spastic constriction, especially if the tooth is carious, and the caries reaches the said cord.

As in the gout there is a pain, redness, a tumour, and a little fever, so they sometimes appear with the tooth-ach. There is also frequently a copious discharge of saliva, which proceeds from a painful spasm, which constricts the lymphatic and venous vessels.

As the rheumatism appears in temperate, and a sudden change of weather; so it is with the tooth-ach, especially when the weather is hot and cold by fits.

The whole intention of cure consists in deriving and diverting the impure scorbutic serum from the head, and then carrying it off through proper emunctories; and afterwards in strengthening the parts.

This is to be done by saline, emollient, purgative clysters; by warm pediluvia of rain-water and wheat bran, with Venice soap, and used just before bed-time; by laxatives of manna and cassia dissolved in whey or asses-milk or mineral waters. If the patient is plethoric or full of blood, bleeding in the foot will derive the humours from the head.

Sudorific remedies are also proper, but more especially an electuary made of rob of elder-berries, burnt-hart's-horn, diaphoretic antimony, and a few grains of nitre, which cannot be too highly praised. Or an ounce of the rob may be taken in broth to promote a diaphoresis; and it may be used externally, dissolved in beer, in the manner of a gargle, which will yield immediate relief to the patient.

Outwardly may be applied bags, filled with pargoric and emollient species, such as elder, melilot, and camomile flowers, bay and juniper-berries, carraway and millet seeds, and decrepitated salt. They must be laid on warm, and are very safe.

A drop or two of oil of cloves, or box, applied to a carious tooth with cotton, are medicines not to be despised. Camphorated spirit of wine mixed with saffron, castor, and opium, made into a liniment, and laid to the gums and hollow teeth, often gives the patient ease.

When the tooth-ach proceeds from a rotten, hollow tooth, it will be best to burn the little nervous cord, which is the seat of the pain, with an actual cautery; and then the cavity may be filled up with a mixture of wax and mastic.

If this cannot, or is not permitted to be done, the only remedy left is to have the tooth drawn. But if the patient is plethoric, it will be safest to bleed first, for fear of a fatal hæmorrhage.

A small pill, made of equal quantities of camphor and opium, and put into a hollow tooth, is often beneficial. Some greatly recommend a small plaister of tacamahac laid on the side of the face, upon the articulation of the jaw-bone, or upon the temples.

But above all, the root of iris lutæa, or the yellow water flower-de-luce, rubbed upon the tooth that is painful, or the root itself chewed in the mouth, in an instant, as if by a charm, drives away the pains of the teeth, arising from what cause soever.

It is now become a practice, especially in France, upon drawing a sound tooth, to replace it in its socket: where, with proper precautions, it will fasten again. Musgrave is the first who recommends this practice. After the extraction of the tooth, he advises a gargle of honey, mixed with the juice of the herb mercury common salt, and spring water, and then to put it in its former place; and adds, it will become more useful than before.

The French operators have improved this hint; and when the tooth is rotten, or otherwise unfit to be replaced, they put another sound human tooth in the room of it. when it can be had; otherwise one of any other animal that is of a size suitable for the purpose.

De la Motte, in the tooth ach, advises to make a small round sticking plaister, about the bigness of a silver groat, and to put a flat bit of opium in the middle of it, of a size not to prevent the adhesion of the other. This is to be laid on the artery near the cavity of the ear, where the pulsation is most sensible. He affirms, there are few cases that this will not relieve.

Of the EAR-ACH.

THE ear-ach is a grievous pain in the meatus auditorius, or cavity of the ears, proceeding from a sharp extravasated serum affecting the nervous membrane which lines the meatus auditorius.

This disorder frequently attacks those who are subject to rheumatic and serous desfluxions; or it may arise from a sudden suppression of sweat, or from the head being exposed to cold winds when it is moist with sweating. The cause is often an inflammation or ulcer of the ear, attended with a remarkable heat, and tense beating pain, a redness, a fever, and even sometimes a delirium. Sometimes it is excited by worms; and then there is a wandering, cutting, gnawing pain.

The ear-ach is sometimes so violent as to cause a delirium, with the highest inquietude and anxiety, inasmuch that the patients often fall into an epilepsy through the violence of the pain.

The ear-ach is sometimes a symptom of acute fevers, when the morbid matter is translated to the ear, as in the Hungarian disease, when deafness or difficulty of hearing arises. When it happens in the declension of a fever, it is a certain sign of recovery; but then the disorder is in the internal part of the ear, and the auditory nerve. When the matter is translated to the external part, then the ear-ach arises; which, unless speedily appeased, may deprive the patient of life. Those who have the ear-ach from a fall, and a sanious matter runs out of the ear, are all carried off.

The principal scope is to ease the pain, which may be

Vol. III. Num. 74.

done with nitrous and cinnabarine powders, and with emulsions of the greater cold feeds; but if these are ineffectual, we must have recourse to opiates, such as the florax pills, or the thebaic tincture.

Outwardly lay a plaister to the temple of the affected side, composed of mastich, galbanum, saffron expressed oil of nutmegs, and opium. Afterwards let the ear be held over the vapour of milk, with the fragrant and emollient spices. Also, fill a hog's bladder with the decoction of milk of flowers of mallows, mullein, elder, mellilot, camomile, linseed, and a little saffron, and apply it to the part affected. Likewise the smoke of tobacco blown into the ear, and an infusion of millepedes in salad oil, are thought to be of great efficacy when the inflammation is caused by a sharp serum.

Cantharized spirit of wine, especially with saffron, made pretty hot, and a few drops of it put into the ear with cotton-wool, is a great resolvent; it should also be rubbed into the parts behind the ear. Or oil of almonds with camphor may be used in the same manner; laying over either of them a hot bag filled with resolvent herbs, as fage, penny-royal, wild thyme, wild marjoram, camomile flowers, Florentine orris, fennel and caraway seeds, with camphor. When the patient is plethoric, bleeding is convenient.

The most violent ear-ach from taking cold, may be infallibly cured, in a very short time, by applying the ear close to the mouth of a bellied jug, filled with a hot strong decoction of camomile-flowers.

When the inflammation will not resolve, a poultice of white bread and milk, or onions roasted under the cinders, or the like, may be often laid hot to the part affected, till it breaks, or the abscess is evident to the eye.

If the ear-ach is caused by any thing got into the ear, it will be best to relax the membranes by oil of almonds, and then cause the patient to sneeze, which forces it out.

When there is a copious flux from the ear after an abscess, the humours must be diverted by gentle laxatives, blisters, cupping, and pediluvia, if the patient is an adult. It should not be suddenly stopped by externals.

Of the STONE in the GALL-BLADDER.

THE signs of it are a fixed pain in the right hypochondrium in the region of the liver, which is constant, pressing, heavy, and sometimes acute; often attended with an ill colour in the face. The pain sometimes reaches to the epigastric region and the pit of the stomach. And the exacerbation is so great, at certain intervals, that the gripes and torture affect the whole cavity of the abdomen; joined with inappetence, a nausea, reaching to vomit, anxiety of the præcordia, cardialgic anguish, costiveness. At length, if the disease is obstinate, and will not yield to the best remedies, the jaundice supervenes. Some of these patients are continually afflicted with gripes, and live in this condition for many years, and generally die of the dropsy. Some feel a heavy, obtuse, deep, obstinate pain, with a tense weight, when the gall-bladder is greatly distended with small soft stones.

If the pain continues very intense and sharp, it draws the whole system of the nervous parts into consent, causing spastic strictures, not only of the adjacent parts, but also

of the remote; distentions of the arms and joints, epileptic convulsions, and likewise a fever with a hard quick pulse, which shews a large rough stone is firmly fixed in the biliary ducts, that will soon hurry the patient out of the world.

But nothing is a more certain sign that these terrible disorders proceed from gall-stones, than when they are voided with the excrements; and then all the symptoms cease at once, except the jaundice, which disappears by little and little, or is easily cured.

If the stones are soft, and of a light colour; or tephaceous and like mortar of plaster, they most probably proceed from the hepatic ducts: If they are rough, hard, angular, and of a deep colour, they proceed from the gall-bladder, especially if attended with most cruel symptoms in their passage through that slender canal. However, stones have been found in the gall bladder after death, which have produced no extraordinary symptoms.

There are two times of the disease, which require two different methods of treatment; in the fit, and out of the fit.

In the fit, the spasms are to be appeased with anodynes and demulcents, such as oil of sweet almonds, and fresh sperma ceti, internally; externally, the fat of a wild cat, or a beaver, &c.

Demulcents are, milk, sweet whey, emulsions of the cold seeds, infusions or decoctions of marshmallow roots, with wild poppies, elder, syrup of marshmallows.

Powders may be made with crabs-eyes, cinnamon, and nitre, with a little saffron, powder of earth-worms, elks-hoofs, &c.

Externally, emollient epithems, and sacculi, filled with carminative ingredients. As also lenient clysters and laxatives of manna, rhubarb, cream of tartar, and the like.

Out of the fits, opening infusions and decoctions; which resolve, discuss, and promote excretions; such as tincture of rhubarb, dog-grafs, asparagus, parsley, pimpinel, afterwards adding rhubarb, terra foliata, tartar, or sal. polychrest, and syrup of marshmallows, which must be used a long while.

Some praise the roots of dog-grafs, and the juice of dog-grafs, as a specific.

Some use the powder of millepedes with neutral Salts.

Epithems made of camomile flowers, leaves of scordium, wormwood, and carduus benedictus, elder-flowers, water and red wine, used often in a day, are beneficial.

But if these fail, after long use, the only refuge is in mineral waters, among which the Pyrmont is not the least ineffectual.

These are also properly used by way of prevention, with exercise, and decoctions of the aperient roots.

Of the GRAVEL and STONE.

A NEPHRITIC paroxysm is attended with a fixed pain in the region of the loins, bloody urine, voiding of gravel or small stones, a numbness of the thigh on the side of the part affected, a drawing up of the testicle on the same side, a nausea and vomiting. After the stone is fallen into the bladder, the urine presently becomes very thick, turbid, blackish, and in great quantity.

When the stone or gravel begins to move and make its way into the ureters, then the pain begins, which is more or less sharp according to the size and figure of the stone. It is sometimes so violent, that, besides a coldness of the extreme parts, there is a nausea vomiting, and a spastic constriction of the precordia, a difficulty of making water, a constipation of the belly, a straitness of breath, a stupor of the thigh, a retraction of the testicle to the *os pubis*, inquietude, loss of strength, a syncope, convulsion-fits, or a total stoppage of urine.

When the violent pain has continued for several days and nights without intermission, and has brought the patient exceeding low, attended with an entire suppression of urine with a coldness of the extreme parts and convulsions of the tendons, it is a sign that death is at hand.

Nor is it a good sign when the stone has continued a long while in the ureter; for then the appetite decays, and a nausea and reaching to vomit supervene, till the patient is consumed with a hectic heat, and the approach of death is hastened. Sometimes the pain is attended with an inflammation of the stomach or intestines. Some, from a stoppage of urine, fall into a dropy of the breast, a lethargy, or convulsions.

The whole intention of cure consists in the easy exclusion of the stone, and the preventing the breeding of others. HOFFMAN.

If the patient is of a sanguineous temperament, take away ten ounces of blood on the affected side; and then let him drink, as soon as possible, a gallon of posset-drink, in which two ounces of marshmallow roots have been boiled. Then give an emollient clyster.

When the posset-drink has been vomited up, and the clyster returned back, give a pretty large dose of an opiate; that is about 25 drops of the thebaic tincture, or 15 grains of the pil. saponaceæ.

Also let a bath or femicupium be prepared, of a decoction of althea roots, linseed, sænugreek seeds, and chamomile flowers; to these may be added, a few white poppy heads.

In the nephritic disorder, the grand point is the evacuation of the sabulary matter lodged in the pelvis of the kidneys, or in the ureters. Bleeding serves to remove the tension and inflammation; and emollient clysters are of a double service, because, by fomenting the slender tubes, they relax the contraction, and, by unloading the lower bowels, they remove the pressure against the ureters. The worm bath opens the passage yet more, greatly relaxing the abdominal muscles, peritonæum, and intestines; the bladder is also relaxed by it, and consequently the oblique insinuation of the ureters through its several membranous is less liable to obstruct the evacuation of this sandy matter into its cavity.

By moderate diuretics, and emollient medicines, this discharge is assisted; while anodynes suspend the pain, and procure a paralytic resolution or a spasmodic contraction of the ureters, and thereby contribute not a little to open the passage.

These appear to be the most considerable methods for the relief of this disorder, which is but imperfectly managed without the united assistance of all, and which, used together, seem the utmost that art can furnish.

A turpentine clyster is generally accounted very serviceable in a fit of the gravel.

Hesler recommends the solution per deliquium of the sal diureticus, or the terra foliata tartari, mixed with a fifth part of the thebaic tincture, of which 50 or 60 drops may be given now and then, which will ease the pain, and gently expel the stone or gravel.

When the stone is too big to pass, the diet ought to be cool and diluent, to hinder the growth as far as possible. The diuretics that gently resolve, are parsley, fennel, scorzonera, mallows, and tea; dandelion, fucory, oats, barley, honey, honey and vinegar; nitrous salts, as dulcified spirit of nitre: The most soft cooling diluter is whey; the best emollients are a decoction of marshmallows and linseed tea.

When a small stone passes through the ureters into the bladder, it is generally expelled; but if it happens to stay in the bladder, it increases by the apposition of fresh matter, or in an orbicular manner, while the original stone remains like a real kernel. These additional coats are either red, white, ash-coloured, or bluish.

The stone in the bladder may cause an inflammation, with its symptoms; as also pressures, attritions, ulcers, purulent urine, strangueries, obstructions of the urethra, an inability to discharge the urine, unless in a supine posture; a hectic fever, and a consumption. Sometimes the stone gets into the urethra, and plugs up the passage.

A stone in the kidneys may be known from a dull obtuse pain therein; from bloody urine after walking in a rough way, or after violent motion of the body, especially by being hooked in a coach or other wheel'd carriage; from having voided stones formerly; and from the urine's being mixed with caruncles, pus, and filaments.

A stone of the bladder is known from a pain at the time of, as well as before and after making water; from the urine coming away by drops, or stopping suddenly when in a full stream; by a violent pain in the neck of the bladder upon motion, especially on horseback, or in a coach over the stones; from a white, thick, copious, stinking, mucous sediment; from an itching in the head of the penis; from a tenelms while the urine is discharged; by searching, with introducing the finger in the anus, or with a catheter; as also from the effects produced by the stone before mentioned.

As to the cure of the stone in the bladder, the medicines of Mrs Stephens were lately much in vogue as a dissolvent; and Dr. Hartley, by leaving out the superfluous part of them, has reduced them to the following form.

1. Take 2 or 2½ scruples of calcined egg-shells, thrice a day, in any convenient liquid, drinking after each dose a third part of the following decoction:
2. Take 2 or 2½ ounces of Spanish soap, and dissolve it in a sufficient quantity of boiling water; filter, and sweeten with honey or white sugar.

The powder may be taken in three or four spoonfuls of any liquor that is not acid: If the largest quantity of the decoction is taken, it will be best to divide it into four doses.

The egg-shells must be calcined in a crucible eight or ten hours, to bring it to a lime; and then be exposed to a dry air, for six weeks or two months, that is, till they

slacken or fall off into an impalpable powder, which must be sifted and put into bottles well corked.

The taking of these medicines must be continued for some time after the complaint ceases, lest any part of the stone should remain, which would be then rugged and unequal, and occasion exquisite pain afterwards.

It is common, after a few days use of these medicines, to have a great increase of pain in making water; at which time, opiates, emollients, warm baths, fomentations, a soft diet, and rest, are proper.

Dr Hales, after several trials of the different ingredients of Stephen's medicines, found that the dissolving power of them lay in the lime. And Dr Jurin, having taken soap-lees, the ingredients of which are potashes and lime, beginning with a few drops, and increasing the quantity, till he took an ounce, or an ounce and a half, every day in a proper vehicle, was cured of bloody urine, pain, &c. and passed several stones; after which he had no uneasiness. Hartley thinks the capital soap-lees are best taken in milk, half an ounce of which requires half a pint of milk. He thinks an ounce and a half, or two ounces, may be taken thus every day with perfect safety.

But Hales rightly conjectured, that lime-water alone was likely to have a good effect in dissolving the stone; which put Dr Whytt upon making experiments therewith, which have happily succeeded; whence he proposes the following method of cure.

Let the patient swallow, in any form, an ounce of Allicant soap every day, and drink three pints or more of oyster or cockle shell lime-water. If the soap be taken in pills, it may be divided into three doses: the largest may be taken early in the morning fasting, the second at eleven before noon, and the third at five in the afternoon, drinking after each dose a large draught of lime-water, the remainder of which may be drank at meals, instead of the usual liquors.

The disagreeable taste of the lime-water may be mitigated by adding a very small quantity of new milk to it; and is quite destroyed by washing the mouth immediately with a little vinegar and water, and carefully spitting it out again. A dram and a half or two drams of juniper-berries, infused in every quart bottle, will mend its taste much. But if the patient dislikes pills, let him dissolve an ounce of soap in a pint and a half of warm lime-water made of shells, which have been long exposed to the weather; and take this at three different times, drinking the rest of the lime-water by itself.

If the shell lime-water cannot be had, let him take the same quantity of stone lime-water, with at least an ounce and a half of soap, because it increases its dissolving power.

If there is an invincible aversion to soap, there is reason to think, from experiments that have been made, that oyster-shell lime-water alone, taken in larger quantities, will have greater effects in dissolving the stone, than stone lime-water even when assisted by soap.

At first the patient should begin with smaller quantities of lime-water than that mentioned above, which he may increase by degrees, and ought to persevere in the use of it, especially if he finds any abatement of his complaints or symptoms of the stone's dissolving, for several months, or, if the stone be large, years; during which he should abstain from acid or fermented liquors.

For his drink, he may use milk and water, or a potion made with roots of marshmallows, parsley, and liquorice. But if he has been accustomed to more generous liquors, he may drink small punch made without acids. Spirits must not be drank at all, nor the weak punch but very sparingly. It will be also proper to forbear the use of salt meats, honey, and acid fruits, or at most to use them sparingly. Artichocks, asparagus, spinnage, lettuce, succory, parsley, purflane, turnips, carrots, potatoes, radishes, green-pease, may be safely used; but onions, leeks, and celery, should be preferred to most other vegetables.

The patient ought to drink no more of any liquor than is sufficient to quench his thirst; and he should retain his urine as long as he can without uneasiness, that it may have the greater time to act on the stone.

If the lime water occasions costiveness, it will be necessary now and then to take a purgative; the most proper are aloe, manna, rhubarb, senna, or jalap.

Such as have a stone in the bladder, should, while they are taking the medicines, have four ounces or upwards of tepid shell lime water injected into the bladder every day, and retain it as long as they can without pain, and should evacuate their urine immediately before injection.

Were it not for the trouble of introducing the catheter, an injection might be made at least twice a day; and if a flexible catheter were always kept in the bladder, it might be done at pleasure, and the dissolution of the largest stone quickly procured.

That the injection of the bladder may be more safe, and attended with less uneasiness, a dram of starch may be boiled in six or seven ounces of lime water, and just be brought to boil over the fire. The fourth part of the yolk of an egg, being mixt with six ounces of lime-water, does not weaken its virtues any more than the starch, and may be occasionally used in its stead.

Such as have no stone in the bladder, but are frequently troubled with fits of the gravel in the kidneys, may probably prevent them, by drinking every morning a pint of shell lime-water, two or three hours before breakfast; and though it may be too small a quantity to dissolve the stone, yet it may prevent any new concretions.

Of the RHEUMATISM.

The rheumatism chiefly attacks persons in the flower of their age, after violent exercise, or a great heat of the body from any other cause, and then being too suddenly cooled: but spares neither men nor women, old nor young, especially if the person is full of blood depraved with any kind of acrimony. The disease is nearly a-kind to the gout.

It begins with chilness and shivering, followed by inquietude and thirst. Which is preceded with spontaneous lassitude, a heaviness of the joints, and coldness of the extreme parts. When the fever appears, there is an inward heat, chiefly about the præcordia, attended with anxiety. The pulse is quick and strait, the appetite is lost, and the body costive. In a day or two, sometimes sooner, the patient feels a racking pain, sometimes in one joint, sometimes in another, but more frequently in

the wrists, shoulders, and knees; frequently shifting from place to place, and leaving a redness and swelling in the part visited last. The pain is exasperated upon the least motion; it sometimes attacks the loins and cox-ndix.

When it seizes the loins, it is called the lumbago; and there is a most violent pain in the small of the back, which sometimes extends to the os sacrum, and is like a fit of the gravel, only the patient does not vomit. If this disease is unskillfully treated, it may continue several months or years, but not always with the same violence, but by fits. If it continues and increases, it may cause a stiff joint, which will scarce yield to any remedy.

Its proximate cause seems to be the inflammation of the lymphatic arteries, of the membranes near the ligaments of the joints, but not so violent as to bring on a suppuration. The blood is like that of persons afflicted with the pleurisy.

Take away ten ounces of blood on the side affected. This must be repeated three or four times, or oftener, once every other or every third day, according as the strength of the patient will bear.

The diet must be very thin, and an emulsion of the four cold feeds may be prescribed; and also a poultice of white bread and milk, tinged with a little saffron, may be laid on the parts affected.

If the patient cannot bear frequent bleeding, after the second or third time, give the common purging potion every other day, and an ounce of diacodium at night, till the patient recovers.

If the rheumatism begins with a febrile effervescence, temperate diaphoretics, with nitrous things, in a moderate dose, and often repeated, are beneficial; such as crabs-eyes, burnt hartshorn, amber, cinnabar, purified nitre, with diapnoic and gently anodyne waters, also citron-juice, or its syrup. The common drink should be whey acidulated with citron-juice or cream of tartar; or decoctions of the shavings of hartshorn, roots of scorzonera, succory, liquorice, or fennel-seeds.

To purge, it may be proper to chew or eat rhubarb, from two scruples to a dram, with raisins or currants.

In an incipient rheumatism of the shoulders, nothing is better than a blister laid between the scapulae.

But if the patient happens to be plethoric, nothing is better than a decoction of the sudorific woods, to the quantity of a quart a-day, for a month or six weeks together.

This last is good in the venereal rheumatism, when assisted with crude antimony and mercurius dulcis.

Young persons who are temperate livers, and not addicted to strong liquors, may be cured by a simple refrigerating diet, and moderately nourishing, as certainly as by repeated bleeding; for instance,

Let the patient live four days upon whey alone; and after that white bread may be allowed for dinner, and, on the last days of his illness, he may be allowed it for supper. When the symptoms cease, he may be allowed boiled chickens, or other things of easy digestion; but every third day he must live upon whey only, till his strength returns.

BOERHAAVE's method of cure is to the same effect, only he advises warm baths and strong blisters to be laid upon the part affected, nay, even cauteries themselves.

AREUTHNOT

ARBUTHNOT says, cream of tartar in water-gruel, taken for several days, will abate the pains and swellings considerably, by its acidity correcting the alkaline salts of the blood.

RIDLEY used mercurius dulcis in rheumatic cases, as a purge, with good success, giving a scruple in conserve of violets over night, and three pints of epsom waters, evaporated away to one half, in the morning.

Dr JAMES has wrote a treatise to prove the efficacy of mercurial preparations, as well in the rheumatism as in the gout, which is supported with very good authorities.

And HUXHAM says, that the obstinate rheumatic pains, which remained after the epidemical fever of 1737, would yield to mercurial cathartics; but he preferred to every else what he calls the essence of antimony, which is no thing else but emetic wine made with glass of antimony, with the addition of a little spicy stomachic. This, given to 20 or 30 drops, operates by gentle sweats, and purges in a larger dose very mildly.

HOFFMAN likewise recommends mercurials and antimonials in particular cases; that is, when a violent and obstinate pain afflicts the lower parts of the body, about the ossa ischia and the os coccygis, and the patient is of a robust constitution, then the more-powerful chemical medicines may be made use of, such as mercurius dulcis, the solar precipitate rightly prepared, or the medicinal regulus of antimony, to which a decoction of the sudorific woods may be added. From such medicines as these great relief may be expected.

CHEVENE says the hot and inflammatory rheumatisms have all the symptoms of the gout, and like it change from place to place, and by over violent evacuations may be transmitted upon the noble organs. And by the way it may not be amiss to observe, that excessive bleeding, and other violent evacuations, constantly bring on a hectic or dropy on the patient in this case; diseases of a much more dangerous nature in themselves, and far more difficult to be cured, than the original one. And therefore in this disease, only premising so much bleeding as will prevent a fever and mortification, and somewhat abate the pain (which gentle doses of calomel and gum guaiacum will do more effectually, though not more speedily, than bleeding itself) the rest is to be done by large doses of the bark and Æthiops mineral mixed; and a relapse prevented by gentle doses of gum guaiacum, with antimony diaphoretic, and cinnamon of antimony.

PRINGLE observes, that rheumatisms are generally mild, though they sometimes appeared with all the violence taken notice of by Sydenham. For which reason the first sort were generally cured in two or three days by twice or thrice bleeding, and promoting a diaphoresis by the cooler medicines, particularly by vinegar-whew. But if it was intended with an inflammatory swelling of the joints, sweating was improper, and the cure was only to be obtained by repeated and almost daily bleedings. But then it is to be carefully remarked, that those were afflicted with it who were best able to bear these evacuations; and in this disease he thinks frequent bleedings weaken the body less than in any other.

If the pain and swelling of the joints remain after this treatment, three or four leeches must be applied to the

part where the inflammation and tumour are the greatest, and the blood is to ooze till it stops of itself. This may be repeated freely without danger. But unless there is both an inflammation and swelling, leeches will do no service. The best internal medicines, in a true acute rheumatism, are neutral salts, with very small doses of camphor. The diet must be of the lowest kind. All outward applications are to be omitted as long as any fever or inflammation remains.

The chronic rheumatism is either the remains of a rheumatic fever, or a continuation of pains that proceeded at first from lesser but neglected colds. The blood in this case is sly. It is an obstinate disease, but bleeding is the most efficacious remedy. Eight ounces of blood is to be taken away once in eight or ten days, as long as it is sly, or the complaints remain.

Bleeding has been repeated, in many cases, three or four times, to no manner of purpose; nor would the pains abate without decoctions, diaphoretics, purges, and anodynes. Sometimes they have yielded to the cold bath alone.

Dr Clerk of Edinburgh declares the ARTHRITIS VAGA, or flying gout, erroneously called the SCORBUTIC RHEUMATISM, may be often distinguished by the urine of the patient; for certain filaments float in it not so transparent as the urine itself, but when taken out they appear as pellucid as crystal. They will rope to a great length, and when dried turn to a white calx. This he takes to be the moribund matter of the gout, gravel, goutish sciatica, and all true arthritic pains, distinct from the rheumatism. Soap is the best dissolvent of it yet known, half an ounce of which to an ounce may be taken in a day for a month together, if necessary, in the sciatic and other arthritic pains.

Of the Gout.

THE gout is a very painful disease, whose seat is in the joints and ligaments of the bones of the feet; the principal times of its invasion are the spring and the autumn.

In treating of this disease, we shall first give an account of the regular gout, and afterwards of the irregular.

The regular gout usually seizes the patient in the latter end of January or the beginning of February all of a sudden, and without any previous notice, unless the patient has been troubled with crudities of the stomach and indigestion for some weeks before; the body likewise may have seemed to have been puffed up with wind, with a kind of heaviness, which daily increases, till at length the fit comes on; a few days before which, there is a torpor, and as it were a descent of wind down the muscles of the thigh, with a kind of spasmodic affection of them. Likewise, the day before the fit, the appetite is more voracious, but not natural.

Though the patient seems to go to bed in good health, yet about two in the morning he is awakened by a pain which most commonly affects the great toe, sometimes the heel, the ankle, or the calf of the legs, which pain resembles that of dislocated bones; there is likewise a sensation as if water almost cold was poured on the membranes of the part affected. Soon after, a shivering and shaking supervene, with a feverish disorder. The pain which at first is tolerable, becomes more violent in proportion as

the shaking decreases, and grows more intense every hour till night, and then it is at the height; settling itself about the little bones of the tarsus and metatarsus, whose ligaments it affects. Now there seems to be a violent extension of the ligaments, or there is a sensation of their being lacerated, or gnawed by a dog. Sometimes they seem to be pressed or squeezed together. At this time the part affected becomes so exceeding sensible, that they cannot bear the weight of the sheet, nor the shaking of the room by a person's walking about.

The patient is now in great torture, and is continually shifting his foot from place to place in hopes of ease. His body likewise is in as constant agitation as the part affected. This always happens at the accession of the fit. But the pain continues without remission till two or three in the morning, that is, twenty-four hours from the first onset, at which time he begins to be at ease, which he is willing to attribute to the last posture in which he placed the affected member. Now he falls into a gentle breathing sweat, and gets a little sleep, and, when he awakes, perceives the part to be swelled, and the pain much abated; for before, the veins of the member, being turgid, were only more conspicuous than usual.

The next day, or perhaps two or three days afterwards, if the gouty matter is copious, the part affected is a little in pain, which grows more violent towards the evening, and abates at the crowing of the cock.

In a few days the other foot begins to be affected in the same manner; and, if the pain has ceased in the first, the weakness which is left behind soon vanishes. The same tragedy is now acted over again. Sometimes, when the gouty matter is in great plenty, it attacks both feet at once, but it generally seizes one after the other.

After both the feet have been tormented, the fits which follow are out of rule, both as to the time of invasion and the duration; only the pain grows more intense at night, and remits in the morning.

From a series of these small fits arises what is called a fit of the gout, which is longer or shorter, according to the patient's age. For it is not to be supposed that, when a patient has been laid up with the gout two or three months, that it is a single fit, but rather a series or chain of small fits, which continually grow shorter and milder, till the peccant matter is at length consumed, and the former health restored. This happens to the more vigorous, and whom the gout seldom visits, in fourteen days; to persons advanced in years, who have often felt its rage, in two months; but those who are debilitated with age, or the long stay of the disease, it does not leave, till summer, being pretty far advanced, drives it away.

For the fourteen days the urine is higher coloured, and deposits a sediment like gravel, and not above one third of what the patient drinks passes off by urine; the body on the first day is costive, the appetite decayed, there is a shivering towards the evening, as also a heaviness and troublesome sensation in the parts not affected. When the fit goes off, there is an intolerable itching in the affected foot, chiefly between the toes, from which and from the feet fall branny scales, as if the patient had swallowed poison.

The disease thus terminated, the patient's good habit

of body and appetite return in proportion to the severity of the pain in the last fit; and in the same proportion the next fit will be either accelerated or retarded; for, if the last fit was very severe, the next will not come on in less time than a solar revolution.

Hitherto you have an account of the regular gout, and its genuine phenomena; but when it is disturbed by incongruous medicines, and the patient is worn out by the long continuance of the disease, it becomes irregular, and the substance of the body is as it were changed into a fomes of the disease, and nature becomes unequal to the task of conquering the malady thus changed, in the accustomed manner.

The feet were at first the seat of the disease, but now it attacks the hands, wrists, elbows, knees, and other parts of the body. Sometimes it so distorts the fingers, as to make them resemble a bunch of parsnips, and at length stony concretions appear about the ligaments of the joints, which, breaking through the skin, resemble chalk, or crab's eyes. Sometimes the gouty matter invades the elbows, and creates a whitish swelling of the size of an egg, which soon assumes a red colour, and becomes inflamed. Sometimes it affects the thigh in such a manner, as if a great weight was hanged thereon, and yet without any remarkable pain. From thence it descends to the knee, which it handles more roughly, hindering all motion, for the patient continues in the same place and posture as if he were nailed to the bed.

Now the gout afflicts the patient all the year, except two or three months in summer; and the particular fit, which did not last above a day or two, continues ten or fourteen days; and the first or second day after the onset, he is disturbed with sickness as well as pain, and a total loss of appetite.

His limbs also begin to be contracted and unapt for motion; and though he can stand, and perhaps creep about a little, yet so slowly, that you can scarce perceive he gets forward at all. If he strives beyond his strength, hoping by exercise to regain his legs, and to become less susceptible of pain, the fomes of the disease will attack the viscera in a more dangerous manner. The urine is like that of a person troubled with a diabetes, and there is a troublesome itching in the back and other parts, especially at bed-time.

Nature being at length oppressed with the disease and old age, the fits begin to grow more mild, and, instead of the usual pain, there is a kind of sickness, with a pain in the belly, a spontaneous weariness, and sometimes a disposition to fall into a diarrhoea; which symptoms vanish as often as the pain returns to the joints. And thus, the patient being alternately afflicted with pain and sickness, the paroxysm becomes very long and very tedious.

This disease seldom invades any patient till he is upwards of thirty, and men are more subject to it than women; as also persons of acute parts, who follow their studies too closely, especially in the night, with an intense application of mind. Likewise those who live high, and indulge their appetites, drinking plenty of rich generous wines; or who use acids too freely, or white eager wines; or who have been addicted too early to venereal pleasures; or whose bodies are large, gross, and full.

Those

Those also are liable to it, whose sweaty feet are too suddenly chilled; or who suffer their feet to sweat in wet shoes and stockings. Hence hunting and riding in in the cold are pernicious. It may likewise be received by contagion, and is hereditary, descending from father to son.

The curative indications require, first, that the primæ viæ be set free from a load of indigested crudities, and the viscera be restored to their pristine vigour: that by these means the aliments may be duly concocted and assimilated into healthy fluids, and such as will pass freely through the smallest vessels; while whatever is unfit for nourishment may pass off by perspiration, in due time and quantity. Secondly, that the fluid stagnation in, and stufing up the smallest vessels, may be expelled the body, and a free passage through the contracted vessels be restored.

The first intention may be answered by vomits and gentle cathartics, repeated as occasion requires; by bitters, aromatics, antiscorbutic medicines; by alkaline fixed salts, taken in small quantities for a long time; by aliments and drinks that are nourishing, light, easy of digestion, quickly assimilated and taken in due quantity; by powerful exercise often repeated and long continued, and especially by riding in a dry, pure, serene air; by friction, by motion of the affected parts, by going to sleep at early hours.

The second intention may be answered partly by the preceding article, as well as by procuring gentle sweats, by bathing in natural and artificial baths; by sweating in a bagnio; or by the use of volatile salts, and copious drinking of attenuating liquors actually hot, in the morning while in bed, in order to procure a sweat; as also by mercurial purges, taking a large quantity of diuretics after them: by frictions of the whole body, especially the parts affected, with hot, dry linnen cloths, till a redness appear; by cold baths, and the like. These things being used with prudence, and according to the various temperaments of the patient, will yield no small relief, even in the nodous gout itself.

As the proximate cause lies in the vitiated state of the smallest nervous vessels of the body, and of the fluid that passes through them, it is no wonder that bleeding will not reach the matter, state, or cause of the disease: yet it may sometimes do good by accident, by causing a small revulsion, and by abating the urgent symptoms.

Nor will emetics or cathartics yield so much relief as is commonly thought, because they often raise a disturbance in the nervous fluid, diminish the other fluids, and weaken the expulsive faculty. But much greater benefit may be expected from sudorifics rightly administered.

Nothing is more fatal than to hinder the gouty matter, now grown mature, and remaining unexpelled, as well as uncorrected by proper medicines, from falling on the usual parts, which indeed cause great pain, but no danger. If it invades the brain, it will occasion apoplexies, palsies, a delirium, weaknesses, dozing, tremors, or universal convulsions: If it attacks the lungs, it produces an asthma, a cough, or a suffocation; if the intercostals and pleura, a convulsive pleurisy; if the abdominal vi-

scera, nausea, anxieties, vomiting, belching, gripings, or spasms of the viscera. It is almost incredible how many diseases it creates, which are suddenly mortal; or at least not to be cured: but by reviving the fit of the gout, which had been disturbed, and rendering it as severe as possible.

These last mentioned evils happen from injudicious applications of narcotics, refrigerants, astringents, or incraffants; or from medicines which cause a revulsion from the diseased part, or from debilitating, evacuating, or suffocating remedies. Hence bleeding, purging upwards or downwards, plasters, poultices, of the nature above-mentioned, and all opiates, produce these effects; as also a spontaneous weakness brought on by extreme old age; or from the extreme parts being so obstructed, corrupted, withered, or perished, that the morbid matter cannot pass through them any longer.

To abate the excessive pain in the part affected, if there be an absolute necessity, opiates may be given internally, and the patient may drink plentifully of hot whey, or any other liquor of the like nature. External emollients and anodynes may be used laid on pretty hot, or the part affected may be beat with nettles, or it may be anointed with terebinthinated balsam of sulphur, or tow may be burnt thereon.

Though there is nothing of any moment to be done in the fit, yet it will be proper to abtain from flesh for some days, and to live upon water-gruel, or such like diet; but no longer than the stomach is averse to flesh, for fear of bringing on a disturbance of the animal spirits; but then great care should be taken in the diet, both as to quantity and quality.

As soon as the pain is almost gone, and the swelling and the weaknesses only remain, nothing can be better than warm stomatic and spicy purges, doled and repeated according to the strength of the patient. This being premised, if the patient's strength is impaired, and his flesh wasted, give asses milk with pearl, half a pint or a pint in a morning early, and at five or six o'clock in the afternoon; and to keep up the appetite which the milk commonly palls, and to prevent its cooling effects on the stomach, a light bitter made of gentian, cinnamon, and orange-peel only, the last double to the other two, infused in sherry or white wine, and taken two hours before meals, may be used most conveniently. This course may be continued two or three weeks; after this a course of Bath or German spaw waters with steel, riding, a light white food diet, and generous wine drank temperately, will be most proper.

Out of the fit, those things are most proper which promote the concoction of the aliment, whether by medicines, exercise, or diet.

In the diet there is a medium to be observed; the patient should neither eat more than the stomach will digest, nor be so abstemious as to defraud the parts of such a proportion of aliment as is necessary to maintain the strength and vigour. As to the quality of the food, the patient's palate is to be consulted: but he should dine upon one dish of meat only; for several kinds of flesh, eaten at the same meal disturb the digestive faculty more than the same quantity of any one sort. As for other things,

the patient may feed upon what he likes best, provided it is not sharp, nor salted, nor seasoned with spices. He should eat no fupper; but instead thereof should drink a draught of good small-beer, whereby the breeding of the gravel may be prevented. If the patient is troubled with the gravel or stone, and makes bloody water, he may purge with manna once a week, and take a paregoric at night.

The most suitable drink is such as is not so strong as wine, nor so weak as water, for the latter by its coldness will deprave the stomach. Of this sort is the London table beer, or water with a little wine. But, when the gouty matter has seized the whole body, he must abstain from all fermented liquors, though ever so mild and small.

But if the patient has been used to strong or spirituous liquors, or is advanced in years, or through weakness cannot digest his aliment, he may, at meals, indulge himself with a draught of Spanish wine, which is better than French.

Regard must likewise be had to the symptoms, which, in the fit, endanger the patient's life. The most common is a weak and languid stomach, attended with sickness and gripes, as if from wind. In this case nothing is better than a glass of Canary drank now and then, together with exercise. But, if the symptoms will not admit any truce, give twenty drops of the thebatic tincture in spirituous alexiterial water, provided the head is not attacked, and let the patient compose himself to rest.

If the nephritic pains should come upon the gout, which often happens, let the patient omit all other medicines, and drink a large quantity of posset-drink, in which the leaves and roots of mallows and marshmallows have been boiled. Then let a clyster be given, and afterwards a large dose of laudanum.

When the gout has seized on the head, it is to be treated as any other head-ache, or as an inflammation of the brain and its membrane; bleeding in the arm or jugular, cupping on the back, and blistering between the shoulders, but especially on the ancles, to give the gouty humour a vent downwards. In young and strong constitutions mercurial and antimonial vomits will do wonders. Likewise gentle stomach purges are to be poured down continually, that is, two or three spoonfuls every third hour, till the effect is obtained.

Mercurial vomits are not only proper for the gout in the stomach, but they are absolutely necessary as well as mercurial purges, when the gout becomes fixed to, and permanent in a place, as also when it is dispersed all over the habit like a rheumatism. These active medicines must first render the humours fluid, which gum guaiacum, with diaphoretic antimony, persisted in, will afterwards carry off.

Of the SCIATICA, or HIP-GOUT.

THE sciatica is a violent and obdurate pain in the hip, chiefly in the joint where the head of the thigh bone is received into the acetabulum of the coxendix. The pain will sometimes extend itself to the lower part of the loins, to the thigh, leg, and even to the extremity of the foot; yet, outwardly, there is no swelling, no inflammation, nor change of colour in the skin.

Sometimes there is such a spasm of the muscles on the side affected, that the patient cannot stand upright, without the utmost pain.

When the sciatica has continued very long, there is such a collection of pituitous humour in the cavity of the joint, that, by relaxing the ligaments, it often causes a luxation. Sometimes it causes an aridura, or wasting away of the adjacent parts.

When the pain leaves the hip, and moves downwards, it is a sign that the spasms are resolved. A violent motion of the body generally exasperates the pain.

After a gentle cathartic, or clyster, bleeding will be proper, especially in the ancle; also leeches applied to the hæmorrhoidal veins have been found beneficial. Strong purges are hurtful; but mercurius dulcis given with scammony, or some other purgative, will be of service.

If the patient is old or weak, lenient purges will be most proper; and on the intermediate days a dose of calomel, which is afterwards to be purged off; and so repeated alternately for some time.

Baglivi observes, that if nothing else will do, in pains of the external parts, recourse must be had to caustics, particularly the leaves of ranunculus, or a mixture of quicklime and soft soap, which are beneficial in the hip-gout.

Cheyne observes, that when the gout is dispersed over the whole habit, or is fixed and settled on a particular joint, mercurial vomits and purges are necessary to dislodge it; but the sciatica will not yield to this, and but rarely to any other methods of use; but, by the following method, a perfect cure may always be obtained, if the distemper is a genuine sciatica, though of many years standing.

It consists in taking one, two, or three drams, to half an ounce, according to the strength of the patient's stomach, of the ethereal oil of turpentine; which is that which comes off between the spirit and the oil in drawing off the common oil of turpentine; this is to be taken in triple the quantity of virgin honey, in a morning fasting, for four, five, six, or eight days at farthest, intermitting a day now and then, as the patient's occasions require, or his stomach suffers by it. Large draughts of sack-whey must be drank after it, to settle it on the stomach, or carry it into the blood; likewise every night must be taken a proper dose of Matthew's pills [or half a scruple of the *pil. Japonacæ*] that is, if the oil has been taken in the morning.

To remove the grosser remains and strengthen the weakened part, the patient must take a dram or two drams of flower of brimstone, for some time twice a day, in a tea-cup full of milk. If through great intemperance, or a violent cold, the patient relapses, let him repeat the former medicines for a day or two. Then, to strengthen the *primæ viæ* and enliven the spirits, let him drink the Bath or Spaw waters with steel, and bitters with volatiles.

Of a VIRULENT GONORRHOEA.

A VIRULENT GONORRHOEA, or CLAP, proceeds from impure coition with an infected woman.

This distemper begins and makes its progress in the following manner. The patient, sooner or later, according as the woman with whom he has had conversation was

more

more or less infected, and according to his constitution, by which he may be more or less disposed to receive the infection, is first seized with an unusual pain in the genitals, and a kind of sensation like a rotation of his testicles. Afterwards, if the prepuce constantly cover his glands, there appears an eruption or pustule, which by its size, colour, and figure, resembles a spot of the measles; presently after appears a weeping matter like semen, which daily changes colour, and becomes more purulent and more yellow, till at length, if the disorder be highly virulent, it assumes a greenish hue, or appears like a thin sanious matter mixed with blood.

The pustule at length becomes an ulcer, commonly called a chancre, at first not unlike the thrush in children's mouths, which, daily eating deeper and wider, at last is encompassed with hard and callous lips.

Those whose glands is uncovered, seldom have such a pustule, either because it is hardened by being continually exposed to the air, or by the frequent rubbing of the shirt, and so is less liable to imbib the infection.

The running brings on a heat or smarting in making water, which is most violent when it is over, for then it seems to burn the whole duct of the urethra.

Another symptom is the cordee, or contraction of the frænum, by which the penis is bent downwards. There is likewise, when the penis is erected, great pain as if compressed transversely with a strong hand. This chiefly happens in the night, when the patient is warm in his bed.

Sometimes the urethra being eaten and excoriated with long running of the acrimonious pus, nature breeds a soft spongy flesh, to supply the defect, which daily increasing forms caruncles or carnosities, so far as to plug up the urinary passage and stop the urine. However, the little adjoining ulcers continue to pour forth a kind of an ichor; and this state is not only troublesome to the physician, but almost as bad as death to the patient.

It also often happens, through some violent motion, or the ill-timed use of astringents, that the sanies which should be carried off by the gonorrhœa, is translated to the scrotum, and causes one or both of the testicles to swell and inflame with intolerable anguish and pain; the running at the same time decreasing, while the scalding of the urine is as great as ever.

To these symptoms may be added the phimosis, which happens when the prepuce cannot be drawn back to uncover the glands; but this the case of many in a healthful state. Also the paraphimosis or paraphimosis, when the prepuce, being swelled, cannot be brought forward to cover the head of the penis. There are sometimes also watery bladders or vesicles called crystallines, and at length buboes or swellings of the glands in the groin. When these last appear, the lues venerea is generally supposed to begin.

Women are not subject to such a variety of symptoms as men; their chief complaints being a difficulty of urine, and a running; however, they are liable to chancres and venereal warts as well within as on the outward parts of the labia pudendi, as also to buboes in the groin. As for the cordation of the sphincter vaginæ, purging up as it were the external orifice, this is not a phimosis, though by some improperly so called.

The cause of a virulent gonorrhœa is a taint by impure coition, conveyed from a woman infected with a malignant gonorrhœa, or the lues venerea, first to the genitals of a man, and afterwards through the pores to the lymph or seminal liquor; the due crasis and natural mixture it entirely destroys, by inducing partly a caustic and corroding, and partly a putrid state thereof. Hence arise the pains and heats, the tumours, the inflammations, and the exulcerations of the genitals: For at first the glands is only affected, whilst, in coition, the poison insinuates itself into the open pores. Then it soon proceeds to the glands of the urethra, then to the præstata, which are porous, and afterwards to the vesiculæ seminales.

If the infected lymph is conveyed to the inguinal glands through the lymphatic vessels, which Cowper discovered to run from the prepuce to the groin; then a venereal bubo is formed, which is a hard tumour without pain. But if the seat of the gonorrhœa is deeper, and an inflammation arises at the beginning of the urethra, where the vesiculæ seminales discharge the seminal fluid, then these vessels are so compressed by the tumour, that the semen cannot be conveyed to them from the testicles, whence it happens that the testicles swell.

As to the prognostics, we must observe, that the greater the infection is, the more violent and obstinate the disorder will prove; though it seldom brings on a pox unless the discharge is imprudently stopped by the preposterous use of sudorifics and astringents; for, immediately on the suppression of the discharge, buboes, tumours of the scrotum and testicles, caruncles of the urethra, and other terrible symptoms appear, together with a confirmed pox. The more regular the discharge is made, the more mild all the symptoms are.

But when the running is small in quantity, the urine is highly fetid, and the matter yellow or green, it is a bad sign.

It is a certain sign the disorder is mitigated, when the painful constriction of the penis in erection, and the heat of urine, are removed; as also when the impaired strength begins to return, and the countenance, which before was pale, assumes a florid or a natural colour.

It is a sign the gonorrhœa is cured, if, upon compressing the penis, a drop or two of thin limpid liquor, like the white of an egg, is discharged.

The regimen, during the time of the cure, requires the patient to abstain from all oily food; and he must also avoid every thing which by its acrimonious quality stimulates to venery; such as spices, bulbous roots, flesh, eggs, fish, and fermented liquors; for the inflation of the penis retards the cure. This is of the utmost consequence; and therefore all venereal incitements, such as obscene books, and whatever else inflames the fancy, should be shunned like death.

Water and whey are the best drink, and seeds and summer-fruits the best aliment.

All possible care must be taken that cold never reach the penis; and that it be kept always moist, lest the pores contracting repel the flux of matter. An emollient and somewhat antiseptic cataplasm will be beneficial.

In the place of mercurials given internally, Astruc dis-
† K k rectis

rests the use of crude quicksilver, as in the common unction, to be rubbed upon the parts, as about the body of the penis, especially under the urethra to the perineum, and so up to the pubes and testicles.

Turner approves of this method in all local affections, such as chancres, a phimosis and paraphimosis from a venereal taint: As also when there is a callosity in the urinary passage, or an induration of the testicles, particularly their epididymes, left after the hernia humoralis, and the like. Nor does he disapprove of it in common claps during the course of the purgation.

If there is no discharge of virulent matter from the penis, it is called gonorrhœa sicca, or a dry clap, the symptoms of which are a dysury or difficulty of making water, and after, from the increase of the inflammation and tumefaction, an ichthy or total suppression of urine.

In the cure of the dry clap, Astruc advises plentiful bleeding in the beginning, to take off the tension, and to abate the inflammation; as also emollient decoctions of mallows, linseed, &c. in milk, to foment the parts; but perhaps it might be better to make a poultice of these ingredients, after Boerhaave's method. to lay to the parts affected; or, which is best of all, to use them one after the other.

He likewise advises lenient clysters, cooling emulsions, and pitans with sal prunella and anodynes between whiles. During the continuance of the inflammation, no mercurials must be used; and if the symptoms increase, threatening an abscess outwardly in the perineum, it is to be forwarded as much as possible by suppurative poultices, and the matter discharged.

Of the Cure of the SYMPTOMS.

I. Of the HERNIA HUMORALIS, or Swelling of the Testicles.

ASTRUC, in the cure, recommends frequent bleeding, and an antiphlogistic regimen, and fomenting the parts with a decoction of mallow-roots and linseed; or milk pretty warm; or an anodyne cataplasim of lily-roots, with leaves of henbane, mallows, and branc urfine, boiled to a mucilage, and mixed with the flower of linseed and oil of lilies. After the inflammation and fever are abated, he advises a gentle purge; after mild resolvents externally, and antivenereals internally.

The hardness of the epididymes is to be dissolved by succinated balsam of sulphur, mercurial plasters, and ointments. During the use of these applications, a suspensory bandage should not be neglected.

When pus is formed in the testicles, it must be discharged with a lancet. If it should leave a fistulous ulcer, he advises a mercurial ointment.

II. Of a BUBO.

ASTRUC asserts, that venereal buboes are of two kinds: the first is essential, happening immediately after coition with an infected person; the second symptomatical, which follows the suppression of the gonorrhœa, or the drying up of the ulceration. He likewise mentions a third, which does not appear so early as the other two, and is therefore a pathognomonic sign of a lues venerea or pox.

He proposes to cure it by mercurial purges, to carry off the humour; in the mean time rubbing a mercurial ointment into the part, to dissolve the induration; which he thinks is more gentle and easy, than to promote the supuration by ripening poultices, and then opening the tumour by a caustic, giving mercurials inwardly at the same time.

De Salt cures all the symptoms by rubbing into the parts a strong mercurial ointment, causing the patient to anoint himself from the anus all along the urethra to the glans and prepuce. The following day he gives a strong dose of jalap, that is, from two scruples to a dram. His diet drink is to be spring-water in which mercury revived from cinnabar has been boiled. If the patient cannot bear much purging, he may have a truce for a day or two, but the ointment is to be continued every night. The first friction gives considerable relief, the second yet more, the third commonly makes the pain cease, and the fourth and fifth generally silence the complaints. Five or six weeks generally perfects the cure.

In buboes, the patient is to rub the ointment into the groin, scrotum, and parts in either sex; purging every day, and drinking the mercurial water; by which means the buboes melt away, the phimosis, paraphimosis, and chancres disappear, and the former health returns. If there is matter already formed in the bubo, then he allows it must be opened. Heister's method is much the same.

III. Of Caruncles and Carnosities in the Urethra.

THE obstacles which hinder the free passage of the urine, according to Astruc, are these which follow. 1. Ulcers in the urethra. 2. Cicatrices left behind after the healing these ulcers. 3. Caruncles. 4. A schirrus on the verumontanum, or caput gallinaginis. 5. Indurations of the prostate and vesiculae feminales. 6. Carnosities rising in and straitening the canal.

He proposes to cure the ulcers by the same regimen as the first period of a gonorrhœa, viz. by repeated bleedings, lenients and refrigerants, to abate the fluxion, and take off the inflammation.

Turner, in the worst cases, would not have the urethra laid open, but only have the perineum well greased with the mercurial liniment, by which he has known many large callosities insensibly dissolve, while the candle or leaden probe, smeared also therewith, has been kept within.

But there has been lately introduced into practice by Daran a new method of curing these disorders with bougies, the composition of which he keeps a secret.

According to him, if the canal of the urethra be open enough to admit the extremity of the bougie, a suppuration will ensue from the diseased part of the urethra, which will in time relax and open the stricture; or, if the stricture opposes the entrance of the bougie, yet still the mere point of the bougie will suppurate it in a small degree, and by and by, though much more tediously than in the other case, by relaxing, open it.

The first discharge procured by a bougie is generally very sanious, and evidently flows from the place where the obstruction is, that part of the bougie only being covered

covered with matter that answers to the obstruction. Again, the cordee, excited by the use of the bougie, is infinitely more painful where the obstruction is, than in the other parts of the penis. It will, it must be owned, produce a cordee in a sound penis; but then it extends through every part of it, and is by no means so painful as the other.

If the symptoms of the strictures, callous scars, caruncles and tumours of the corpus spongiosum urethrae are essentially different, those differences are not mentioned by any writer; except that, when the urethra only is affected, the patient, in making water, voids matter before his urine; but when the prostate glands or vesiculae seminales only are concerned, matter follows the last drop of urine. But it frequently happens that one is complicated with the other.

The properties requisite in a bougie, are a sufficient degree of firmness, that it may be introduced with some force: A suppleness and tenacity, that it may conform to the motions of the body without breaking: A lenient suppurative disposition, to bring on a discharge without pain: And, lastly, a smoothness of surface, that it may not only be introduced with more ease, but that it may lie easy in the passage till it begins to dissolve.

That chiefly made use of is as follows;

R. Emplastr. commun. cum pice Burgund. ʒij. Argent. viv. ʒj. Antimon. crud. pulv. ʒss. M.

The *emplastr. com.* or diachylon, must be made with oil and a little Burgundy pitch added to it, to render it sufficiently tenacious: the antimony must be finely levigated, that it may give a smoothness and good consistence to the bougie.

The quicksilver, whether it be divided in *bals. sulph.* or honey, must not be put into the plaster till the moment before the bougies are made, nor must the plaster be boiling hot at that time. When the quicksilver is mingled with the plaster moderately hot, slips of fine rag must be ready to dip in the composition. They must be of different lengths, from six to nine or ten inches, and about three inches broad. Roll them up loosely, and, taking hold of one extremity with the left hand, let it fall gently on the surface of the plaster, and then draw it out gently. As it is drawn out, it will unroll, and take up a quantity of the plaster upon its surface, equal to the thickness of a silver groat. It may be proper to assist the unrolling with a spatula. The plaster must be hot enough to soak through and discolour the rag. The ladle in which it is melted ought to be broad and flat at the bottom; and the plaster must be kept stirring to preserve it in equal consistence. The bubbles on the surface of the cloth may be smoothed with an iron spatula a little warmed.

One rag will make six bougies of a moderate size; they are best cut with a knife and ruler. They should be made taper at the end, by cutting off a slope about an inch and a half long. When they are rolled up, it must be with that side outward which is covered with plaster; and they must be first rolled up with the finger and thumb as close as possible, before they are rolled upon a board or marble. In the winter it will be proper to hold them a little before the fire to facilitate their rolling.

Before a bougie of any kind be introduced into the ure-

thra, it will be necessary to smear it with sweet oil, that it may go in easily, and not stimulate too much at first. The patient may either stand or lie down in the posture of being cut for the stone; then the surgeon must grasp the penis near the glans, and extend it gently, that the urethra may not be wrinkled, and then it will meet with no impediment but what is occasioned by the disease.

It often happens at the beginning, that the bougie cannot be too small; and then the end must be round, that it may readily slip over the plicae of the urethra; it is also exceedingly desirable that it enter within the obstruction. However, it is necessary to desist from pushing it when once it begins to bend. When it meets with any resistance, to avoid the bending, turn it round with your finger and thumb several times, and, as you turn it, press it a little forwards. If by this method it advances, continue to do the same thing till it stops. But it must be owned that the operator in this case may be easily deceived.

The bougie must be confined in the penis by some kind of bandage, or rather we may keep it fixed in the urethra by a cotton string tied about its extremity, and then passed round the penis; no other thread is necessary.

When the patient is timorous, or the part tender, it may be left in two or three hours in a day only at first, but otherwise six or seven. When the patient finds he cannot bear it, it may be discontinued two or three days, according to the nature of the symptoms.

There are instances of its having first cured, and then brought on a fresh stranguy. In this case, forbear its use for two or three days, and the stranguy will cease.

Some have been able to wear it night and day without intermission; and as they withdrew one, introduced another. And this is a prudent step; for the more suppuration is procured, and the longer the urethra is kept distended, the cure is more likely to be radical. When this cannot be done, the day is better for its use than the night, because in the night it is more subject to erections.

Two bougies in a day generally answer the purpose; one in the morning, and one in the evening, as more suitable to the patient's avocation; though some can walk about with them.

If the testicles should inflame, or any feverish disorder come on, they may be kept in an hour, or half an hour in a day, to prevent the urethra from contracting again till the symptom is removed; to prevent these disorders, the patient should observe a cooling regimen during the treatment.

Some are relieved by the bougie in a few weeks, some not till many months. Generally the cure may be performed in seven, eight, nine, or ten weeks. This is known by the removal of every symptom of the disorder; for some degree of running will generally continue as long as the bougie is employed.

When the patient judges himself well, it will be best to desist gradually, wearing it at first only an hour or two in a day, and then two or three times a week, after which it may be entirely left off. If any gleet still remain, or any obstruction threatens to return, it will be necessary to use the bougie four or five weeks longer.

In suppressions of urine it will be always advisable to introduce the catheter if possible, and indeed to keep it

in the bladder two or three or four days; after which, the canal will perhaps admit a bougie, and then, a suppuration being once procured, it may easily be preserved open.

IV. *Of a GLEET.*

In what manner, says SHARP, a gleet is furnished, cannot well be determined, without first ascertaining the exact seat of a gonorrhœa. That the lacunæ of the urethra are usually ulcerated in a gonorrhœa, is now generally assented to. Yet though all allow the existence of ulcers during that disease, they will not admit that a gleet is the discharge of an ulcer.

But it is most probable, that the running is not all of it a purulent matter, but partly matter, and partly a discharge from the secretory organs, as also from the vesiculæ seminales, when they or their ducts are affected. For the running is produced in less time after the infection than is requisite for the formation of matter in every other instance; and the appearance of matter is frequently the first alarm in a gonorrhœa, the heat of urine and other symptoms of an inflammation and ulceration following sometimes two or three days after.

For these reasons, it is supposed, that the venereal poison, in its first operation, irritates only, and thereby increases the secretion; especially as the same thing happens to the glands of the intestines from purgatives, from the salivary glands, from smoking, &c. As the poison operates more strongly, the inflammation increases, and the ulcers form and extend, when not only the matter from the ulcer is sanious, but all the secretory vessels communicating with the ulcerated lacunæ secrete a thinner fluid than usual; and both the matter and secreted fluids continue to be thin so long as the inflammation is violent.

It is even possible that in some slight gonorrhœas, which disappear in a few days, the venereal poison may not have activity enough to bring on an ulceration of the urethra, but only a mere irritation of the lacunæ. Besides, in other cases, the quantity of the running is generally much greater, if we may judge by analogy, than a few ulcers in the urethra could possibly furnish. Of this we have almost ocular proof in women; for, though the gonorrhœa be exceeding plentiful, yet, upon the nicest inspection, we often cannot find the least degree of ulceration of the vagina, though, if the discharge was purely the digestion of ulcers in that part, it is likely some few of them may be visible.

When the inflammation ceases, and the ulcers of the urethra heal at the same time, the cure of a gonorrhœa is perfected; on the other hand, if the inflammation be only removed, and the ulcers remain open, a gleet must ensue.

It is upon this principle of ulcers subsisting in the urethra, that Daran accounts for the action of his bougie, supposing it to have the property of healing them with a sound cicatrix after the urethra is opened. And, if in the operation it can be understood when there are ulcers, it will not be difficult to comprehend it when there are none; since it seems to have the power of opening every unsound cicatrix of the urethra, and bringing them immediately into an ulcerated state.

There are many who imagine that the prodigious in-

crease of certain gleets at particular times, lasting only for two or three days, and then suddenly abating to their wonted quantity, is inconsistent with a purulent discharge; and therefore conclude a gleet to be nothing but a preternatural excretion from the relaxed vessels of the urethra. But it is probable, that, however the matter of a thick gleet may be furnished by secretion, still the stimulus provoking the secretion is kept up by the subsistence of ulcers, and also that, when the gleet is very thin and in small quantities, it is the mere discharge of those ulcers. A temporary increase of a gleet is not wonderful, because habitual ulcers of every other part of the body are often in a fluctuating state, and generally suffer from excesses of every kind.

Altruc, in this disorder, recommends milk, either of asses, goats, or cows, to be drank morning and evening for some time; then mineral waters, whether chalybeate or vitriolic, for 15 or 20 days; and afterwards ballamics, to deterge and cicatrize the ulcers concealed in the urethra, such as balsam of capivi, from 6 to 12 drops, made into a bolus with powder-sugar; last of all, astringents to dry up the ulcers, and to recover the lost tone of the parts, such as infusions of the leaves of mint, horshound, agrimony, plantain, red roses, shepherd's purse, sage, &c. or the mint-water of Quercetan, so often recommended by Riverius against obstinate gleets.

V. *Of CHANCRES.*

ASTRUC observes, that chancres were the *caries pudendorum* of the ancient writers, and are generally seated on those parts which have a fine and tender covering, through which the virulent sanies, issuing from the exulcerated genitals of either sex, has the easier admittance. Such are the inward duplicature of the prepuce, the inside of the pudenda in women, the nipples of nurses, the lips and tongue of prostitutes. In very bad cases they will appear on the dorsum penis, as well as on the pubes and inside of the thighs.

In the cure of the recent chancre, he first orders bleeding, to abate the inflammation; then fomentations, to resolve the induration; not omitting mercurials in the mean time, but so as to avoid a salivation. After which he advises the use of sudorific decoctions of china, sarsaparilla, guaiacum, and saffras boiled with antimony.

Turner formerly used red precipitate sprinkled on a proper ointment.

Of late years, he says, he always found smocking the parts with cinnabar successful in chancrous ulcerations on the glans and præputium of men, as well as the labia and sinus pudoris of women. His method was to throw a dram of cinnabar on a heater or hot iron, letting the fume ascend through a funnel, or a seat perforated like a clove-stool, all round the diseased parts. This was done every day, and sometimes twice a day for a week. The iron was hot enough to raise flame with smock, but not so fiery red as to make it instantly consume away in flame alone.

VI. *Of the Phimosis, Paraphimosis, and Crystalline.*

THESE are disorders proper to men, except the crystalline; but Astruc affirms, that women have something of the

the same nature; and even extends them to their nipples, where the ulceration constricting the areola or circle round about them irritates the same. The phimosis of women is the constriction of the entrance into the vagina.

He begins the cure with bleeding and gentle purgatives, such as *castia cum manna* and *merc. dulc.* instead of brisk cathartics and emetics, which, as Turner thinks, by making a stronger revulsion, afford speedier relief.

He then advises anodyne emollient fomentations and cataplasms to relax and soften, and afterwards discutients to breathe forth the humours; and, if the penis is soaked therein an hour or two twice a day, the effect will be more certain; but if a stagnation is threatened, and thence a gangrene, the prepuce is to be divided in the phimosis on each side the glans, and the folds of it to be cut through in the paraphimosis; by which the strangled glans may be set free, and the chancre, if any, brought into view. The like must be done for the crystalline, in order to discharge the imprisoned lymph, and forward the subsidence of the prepuce, thereby inflated and puffed up.

The affected parts in women should likewise be fomented with the like emollient and mucilaginous decoctions, of the roots of marsh-mallows, white-lily, water-lily, and the leaves of branc ursine, mallows, linseed, &c. several times a day. Afterwards, a pessary made of linen or sponge dipped in the emollient liquor should be introduced into the vagina.

VII. Of Tubercles and Scirrhus Cords.

The tubercle is a callosity remaining after healing the chancres of the glans, which hinders the free play of the foreskin over the glans. If this will not yield to a strong mercurial unction, the only remedy is circumcision.

The scirrhus cords are tubercles which arise where there has been an ulceration; and may be left under the skin of the penis, sometimes round, and sometimes like a cord. They arise gradually, and disappear with the help of a little mercurial unction, and a course of mercurial purging, unless complicated with other symptoms of a worse kind.

VIII. Of the Porri, Condylomata, Chiristæ, and the like Excrescences.

THE venereal porri, whose seat is the pudenda, if they are recent, small, and soft, sometimes dry and fall off of themselves, after the poison has been destroyed by mercurial frictions; but if they are hard, large, and have deep roots, they will sometimes continue after them, and grow like warts in other parts of the body. In this case they must be cut with the point of the scissors as near the skin as possible, and a mercurial plaster must be prepared with a large proportion of mercury, and mixed with *diach. cum gum.* to promote a suppuration, and to dissolve the callosities at the bases of the porri, before a cicatrix is formed.

But if the basis is hard, and surrounded with hard and deep callosities, slight mercurial frictions must be used; and the wound must be dressed with basilicon, sprinkled with red precipitate, to consume the callosities by little and little, to soften the edges of the ulcers and dispose them to heal. If this should fail, stronger corrosives should be used.

The same directions are applicable to the whole tribe of condylomata, chiristæ, mora, sici, either about the pudenda or anus.

Of the LUES VENEREA, or FRENCH POX.

WHEN a gonorrhœa has continued a long while, or long enough for the poisonous matter to make its way into the blood, or, by astringents given unseasonably, it cannot make its exit, then the patient is infected with the pox.

The buboes in the groin constitute the first degree; then follow pains which cruelly torment the head and joints of the shoulders, arms, and ancles, coming on by fits, but at no certain intervals, unless in the night when the patient is warm in his bed, seldom leaving him till towards the morning.

There are also scabs and scurf in various of the body, which are as yellow as a honey-comb, and which distinguish them from all others. Sometimes they have large surfaces, answering the description which authors give of the leprosy. But the more these scabs are dispersed over the body, the less he is tormented.

All these symptoms gradually increase, especially the pain; which becomes so intense, that the patient is unable to lie in bed. Afterwards nodes or exostoses arise in the skull, shin-bones, and bones of the arms, which, being attended with constant pain and inflammation, at length grow carious and putrefied.

Phagedenic ulcers likewise seize various parts of the body; but generally first begin with the throat, and from thence gradually creep by the palate to the cartilage of the nose, which they destroy, and the nose, being destitute of its prop, falls down flat.

The ulcers and pain daily increasing, the patient sinks under the torment; and being not able any longer to struggle with stench, rotteness, and the loss of one member after another, his mangled offensive carcase is hurried into the grave.

Besides the symptoms proper to the pudenda and parts adjacent, which have been already mentioned, the following are observable in a confirmed pox; which however do not appear in all patients, nor at the same time.

I. The skin, especially about the neck and breast, and between the shoulders, is covered with flat spots like freckles, of a rosy, purple, yellow, or livid colour, sometimes distinct, small and round like lentils, sometimes more large and extended.

It is full of itchy pustules, tetters, and ringworms, a serpigo, a herpes miliaris, and exedens. There are chaps in the palms of the hands and soles of the feet, with itching, from whence proceeds a clear serous liquor, and the epidermis peels off in large flakes.

It abounds with hard, callous, round pustules, rising a little on the top, generally dry, but sometimes moist, scaly, branny, and yellow; frequently on the corners of the lips, and the sides of the nostrils, but more especially on the forehead, temples, and behind the ears. where they appear in rows like a string of beads, and gradually creep among the hair.

The hair not only falls off from the head, but all parts of the body where it grows. Then the nails become unequal,

equal, thick, wrinkled, and rough; afterwards ulcers arise which cause them to fall off.

II. The inside of the mouth, throat, and nose, are also affected; the uvula and tonsils become painful, hot, inflamed, and ulcerated; pustules appear in the roof of the mouth, which degenerate into round, malignant, phagedenic ulcers, which rot the bone as far as the nostrils. The pituitary membrane is likewise liable to pustules, which produce malignant ulcerations that infect the bones of the nose with a caries, particularly the vomer; which being eaten away, the nose falls down; the voice becomes hoarse and low; the gums being covered with aphthæ, ulcerate and rot; the teeth ache, grow rotten, and fall out; and the breath is very offensive.

III. The patient is excruciated with pains in the night-time, when in bed and covered with cloaths: these are either tensive, pricking, pulsative, or rending; fixed or wandering; which sometimes occupy the muscular and membranous parts like the rheumatism, sometimes the tendons and ligaments about the joints resembling the gout; sometimes they are with tumour or inflammation, sometimes without.

IV. The bones are affected in various manners; in the middle exostoses arise, either soft or hard, sometimes with intense pain, sometimes without. The heads of the bones enlarge every way, but unequally, which produces tumours, pains, difficulty of motion, and stiff joints. As the caries increases, they become brittle, and break upon the least effort. Sometimes they are so far dissolved, as to bend like soft wax.

V. When the lymph is infected, the lymphatic or conglobate glands become hard and callous, and form, in the neck, armpits, groin, and mesentery, hard, moveable, circumscribed tumours, like the king's evil. The lymphatic vessels are dilated, extended, and enlarged by a thick stagnating lymph, and form soft encisted tumours or gummata: In the tendons it causes nodes, in the nerves ganglions, and in the ligaments of the joints topus.

VI. Neither do the ears and eyes escape the fury of this disease: for the latter are externally affected with pain, redness, itching, and lippitude; and internally, being loaded with humours, the sight is destroyed, and sometimes a suppuration supervenes. If the vitreous humour of the eyes is thickened, it causes a glaucoma; if the crystalline, a cataract; if the aqueous, hairs or spiders webs seem to float in the air.

The ears are affected with a singing noise, hardness of hearing, deafness, and pain, whilst their internal substance is ulcerated and rendered carious.

After this catalogue of symptoms, it is no wonder that all the animal, vital, and natural functions should be depraved, the face be pale and livid, the body emaciated and unapt for motion, and that the patient should fall into an atrophy and marasmus.

Women have disorders proper to the sex; as, cancers in the breast, a suppression or overflowing of the menses, the whites, the hysterical passion, an inflammation, abscesses, scirrhus, gangrene, ulcer and cancer of the womb. They are either barren or subject to abortion; or the children they bring into the world have an universal erysipelas, are half rotten, and covered with ulcers.

The methods of curing the pox are principally four; 1. The common, by salivation; 2. By giving quicksilver pills; 3. By mercurial frictions, which are to be purged off before a salivation is raised; 4. By sweating, with a decoction of guaiacum.

The safest and most commodious method of salivation is by mercurius dulcis six times sublimed, given inwardly in the milder pox; or by mercurial unction, when the disease is got into the bones.

Fifteen grains of mercurius dulcis may be given in a morning, and the like dose at night, with *electar. e scordis*. After three, four, or five days with this management, we usually observe the fauces to inflame; the insides of the cheeks to be tumid, or high and thick, being ready to fall within the teeth, upon shutting the mouth; the tongue looks white and foul, the gums stand out, the breath stinks; and the whole inside of the mouth appears shining, as if parboiled, and lying in furrows.

The inside of the mouth thus beginning to be wheeled, you may expect soon to see them ulcerated, especially about the salival glands, which empty themselves thereinto. Now it may be proper to desist a day or two, to observe the increase of the ulcers, what sloughs are like to be raised, and what their depth and dimensions are like to prove; from which a near conjecture may be made of the duration as well as quantity of the spitting now begun, and the consistence of the drilling lymph whether more or less fluid.

When the salivation is thus begun, your only business is to encourage your patient cheerfully to go on. Let his diet be small chicken-broth, water gruel, and panada. His drink, small sack-whey, or posset-drink, with a draught of good small-beer with a toast between whites.

Thus, after some days respite, if, after the spitting comes on, you find the patient hearty, his chaps but little swelled on the outside, and as little sore within, the ulcers not increasing, with few or no sloughs appearing therein, the flux also inconsiderable in quantity, you may now give a scruple of *merc. dulc.* in *elect. e scord.* at going to rest, repeating it two or three days following, as you find occasion, and then wait the issue again. This is the safest and most prudent method.

If he should have taken half an ounce of calomel, with little alteration as to the swelling and soreness of his mouth, and as little appearance of his slavering, his pulse and other circumstances favouring the same, and no ill symptom appearing, you may vomit him with viij or x grains of turpeth mineral in conserve of roses, or mixed with x or xv grains of calomel, encouraging the operation with small draughts of common posset-drink between whiles, upon each motion to reach, but not loading the stomach therewith, as is customary in other emetics. If there is occasion, it may be repeated two or three days after, which will forward the salivation more effectually than more doses of calomel simply repeated would have done.

If a salivation cannot be raised to any quantity, as in some it cannot, you must forbear and purge it off, and give calomel once or twice a-week, and purge it off the next day, or two days after.

When the spitting goes well forward, it may be left to take its course till it declines of itself; which, in proportion

portion to the ulcers and thickness of the sloughs about the parts of the mouth, may happen at the end of twenty-one days, or a month from its rising; that is, from the time of spitting a pint and a half a-day, till it comes to three pints, or even five pints, in twenty-four hours, when it gradually goes off again. For often the first four or five days, or a week, are spent in bringing it to the first proportion.

In the more stubborn and rebellious pox, attended not only with cruel night pains, gummata, tophs, nodes, and also rotten or foul bones, if the patient has been used to mercurials, or if salivated before, then the cure must be attempted with salivation by unction.

You may mix an ounce of quicksilver with three ounces of axungia; of which, an eighth part is to be used night and morning, letting the patient rub it in with his own hands gently by the fire, beginning with his ancles up to his thighs and knees, all round his joints, and so to his thighs, which are presently after to be covered with yarn stockings and flannel drawers; then let him use what remains of his eighth part about his elbows and shoulders, wiping his hands clean about the glands of his arm-pits, or those of his groin. His body, during the unctions, should be screened from the cold with a blanket hung behind him, and then be wrapped up in a warm flannel; that is, he must have a flannel shirt, waistcoat and drawers, a cap, a muffler pinning it up thereto behind, and covering all his throat, chin, and cheeks before, to defend them from the cold air. The same things are requisite in the former way. The weak need only be anointed one day.

If, when the ointment is divided into four parts, after the third unction the patient begins to complain of his chaps, you must stay a day or two before you proceed farther: The same when gripes or bloody stools approach.

Where there are a gummata, tophs, and nodes, the ointment must be chafed particularly into those parts, and then apply the mercurial plaster upon them. If the spitting declines too suddenly, give a scruple of calomel every day, or every other day, for two or three times, as you shall see occasion.

When he is a little recovered, and his chaps pretty well, he may eat a little chicken, veal, rabbit, or mutton, well roasted, without sauce or gravy.

The patient should be prepared for a salivation by a lenitive purge or two; and, if plethoric, he should bleed: Likewise bathing in warm water, for some hot, lean, emaciated people, has been found serviceable. Women should be laid down just after their menstrual flux is over. Temperate weather is the most suitable.

If the patient is troubled with sickness and vomiting; if mild, give him freely of a small chicken-broth, posset-drink, or thin water-gruel, refreshing him with a little mulled wine between whiles. But if there is a cardialgia, and intolerable pains at the mouth of the stomach, with incessant vomiting, spasms of the members, fainting, cold sweats of the forehead and eyebrows the patient is in the utmost danger, and you must cease giving mercury, and if possible turn it downwards, by directing the common clyster with 2 or 3 ounces of brown sugar, and as much oil-olive.

To prevent the jaws from being locked up, it is necessary to use a bit of stick covered with a soft rag, which must be held between his backward teeth: But, if there should happen an adhesion of the inside of the cheek to the gum, hindering the patient from eating and opening his mouth, the same is to be carefully avoided.

If, during the salivation, a blood-vessel bursts open, make a little pellet of lint, and cover it with the fine powders of alum or vitriol, or dip it in the tinctura styptica, and thrust it close down into the cavity, which will secure the effusion, being held tight with the finger for a little while. If it happens from the separation of the sloughs from the side of the cheeks, a little oxybate held in the mouth will do the business, or an astringent decoction of oak bark.

If the patient has been without a stool for some days, give an emollient clyster of warm milk, sugar, and oil. At this time he may drink freely of small beer with a toast, barley water, small sack-whey, or posset-drink. For diet, water-gruel, oatmeal-caudle, small chicken or veal broth, a roasted pippin, or a few stewed prunes.

If, notwithstanding your care in giving small doses of mercury, the fauces should suddenly inflame and tumefy, endangering a suffocation of the patient, the most certain relief is to bring the humours downward by sharp clysters, and, if he can swallow it, a cathartic by the mouth.

An ozæna, or ulcer of the nostril, is best cured by a cinabarine fumigation, which subdues the malignity, dries up the ulceration, and disposeth the caries, if any, to a separation beyond all others after which, and sometimes before, calomel must be given and purged off; or, if there are other symptoms of a profound infection, you must salivate by unction.

The like method must be used for ulcers of the palate, uvula, and tonsils. The fume rarely fails to stop the farther erosion, and therefore it is always to be directed, though a salivation is intended. It cures, in two or three days time, the most putrid and corrosive venereal ulcers, or after the second or third smoking.

Astruc disapproves of any other method of salivation but by frictions; and he would have pure mercury ground in a mortar, with just so much turpentine as will reduce it into a brown or black powder, and mix with it equal parts of fresh lard, and so well mixt, that the particles of the mercury shall not be visible by a magnifying glass. He also allows that occasionally there may be double the quantity of lard.

He distinguishes the frictions into weak and strong; for the strong he allows not less than two drams of the ointment, nor more than four. The first time, the patient is to be anointed from the feet to the calves of the legs; two days after, from thence to the middle of the thigh; then the third time, as far as the buttocks. If after the seventh day there appears no sign of a salivation, you must proceed to the fourth friction, from the buttocks along the loins and back to the neck, with a large quantity of ointment. If on the ninth day nothing appears, another friction must be from the wrists to the shoulders.

During the salivation, he allows the patient, if he has strength, to get up sometimes, and sit by the fire; or, if he cannot, to sit up in bed: when he lies down, he would have

have him lie in as prone a posture as he can, that the saliva may be evacuated more easily, and not fall into his stomach.

In the weak or slight friction he allows from one to two ounces of the ointment. The first friction is to be only on the feet; the second on the legs; the third on the knees; the fourth on the thighs; the fifth on the buttocks and perinaeum; the sixth on the loins; the seventh on the back and between the shoulders; the eighth and ninth, if there is occasion, from the arms to the wrists. There may be three, four, five, or even six or seven days between each friction, if the patient is very weak: But the rule is, to look into the patient's mouth before a new friction, that you may be certain not to bring on too plentiful a salivation. The dose of the ointment must be so managed, that, after the fourth or fifth friction, a salivation may come on that is gentle, easy, governable, without a swelling of the head; with only a few aphthae in the mouth, or at most a few superficial ulcers, and the patient not spitting above a pint or two in twenty-four hours: and to this point it must be kept up, with a new friction, if there be occasion. Likewise it may be kept under with clysters and plentiful drinking of the ptisan; and, if necessary, with lenitive purges. This treatment may be continued, *pro re nata*, from 30 to 50 days, or longer.

Till the salivation comes on, the patient may be indulged in weak soups, rice, cream, panada's &c. and even milk for breakfast; but after that they must be left off; and he must drink a large quantity of ptisan to dilute the blood. He may sit up all day, if his room be warm.

If, after a due repetition of mercurial frictions, a salivation does not appear, it generally happens that a looseness, a flux of urine, copious sweats, or at least a plentiful transpiration, will supply that defect, and serve in its stead. In this case, the patient may think himself exceeding happy and fortunate, that he has obtained a complete cure by a method more certain and convenient than by salivation, and without its inconveniences and dangers.

The second method of curing the pox is by a quicksilver pill. This was brought into reputation by Belloste; and though he has kept the composition a secret, yet there is no reason to doubt but it is quicksilver mixed with a certain proportion of a cathartic.

The third method of curing the pox is by mercurial frictions, which De Salt gives as follows:

When the patients have a pox of a long continuance, and the venereal poison is dispersed all over the body, they should be prepared by bathing and drinking whey. But in a recent pox the bath is not necessary, or at least need not be used long, because the blood is sufficiently diluted.

After this, instead of raising a salivation, bring on a flux of the belly; the whole secret of which consists in keeping the body open by clysters of a decoction of fenna and the pulp of cassia, before the frictions are administered; by which the intestinal glands being opened, the mercury will more readily tend that way. When the looseness does not answer the number of the frictions, nor the quantity of the mercury made use of, purge the patient with powder of jalap, and procure copious stools,

which secure the mouth. While the looseness is going on, the friction does the office of a purge; and in proportion as they are repeated, the flux of the belly revives; and when it slackens or stops, have recourse to the clysters and purges of jalap. Pursue this method till the symptoms cease, and till, by the abundance of the evacuations, the venereal poison is entirely drained off.

The last method is sweating with strong decoctions of guaiacum. This we have the first account of from Sir Ulrick Hutton, who pursued it himself. A pound of guaiacum is to be boiled in a gallon of spring-water to one half, and the scum reserved to anoint the sores, and a secondary decoction was to be used for common drink.

But, when salivations and other mercurial courses have failed, the best method of cure is by the root of sarsaparilla; which discovery we owe to Dr Hunter, who put Mr Fordyce, a surgeon in the army, upon making a trial of it; the result of whose experience is as follows.

1. It will commonly relieve venereal head-achs and nocturnal pains in a very short time; and, if persisted in, he believes it will always cure.

2. In emaciated and consumptive habits, from a venereal cause, it is the greatest restorer of the appetite, flesh, colour, strength, and vigour, that he knows.

3. When the throat, nose, palate, or the spongy bones in general, are affected with a slough or caries, it will commonly complete the cure, if persevered in long enough, provided a mercurial course by unction has preceded the use of the sarsaparilla.

4. When the body is covered with dry blotches or moist sores from a venereal cause, it will greatly promote the cure, nay often complete it; but, without the assistance of mercury, there will be danger of a relapse.

5. In simple chancres it will do little service; but, if it is given in cases where the chancres or buboes will not heal or dissolve after the use of the mercurial unction, it will often cure, and do always manifest service.

6. It will often answer, and that speedily, without sweating, confinement, or any strict regimen, at all seasons of the year, when mercurial unctions and long continued courses of strong decoctions of guaiacum, either by itself simply, or compounded with a small proportion of sarsaparilla, have failed.

7. It seems probable, that sarsaparilla root is the only medicine to be depended upon in venereal cases where mercury has failed, or at least has preceded the use of the decoction; for it is not to be trusted alone. When no mercury has been given, it and this decoction may be administered together, and then there will be no room to doubt of success.

8. Mercury alone will cure most venereal complaints, and sarsaparilla will perhaps always cure them when they resist the power of mercury; and therefore a proper combination of mercury and sarsaparilla will probably cure every case that is truly venereal.

The method of using it is this; to three ounces of the sarsaparilla root, which has not been spoiled with age, worms, sea-water, or moisture, add three quarts of river-water, and make it boil as speedily as possible, in an open vessel, till two pints of the strained liquor remain, that is, about two pounds avoirdupois weight; a little liquorice-

liquorice-root added to it will make it more palatable. This quantity is enough for twenty four hours, and may be given at two or three doses either warm or cold. It must be made fresh every other day, and what is not used on the day it is boiled must be kept in a cold cellar. The patient should live abstemiously while he takes it, particularly with regard to wine.

There is another compendious and efficacious method of curing the lues venerea, which has formerly been attempted by the same medicine, but in a different manner, and not with the same success.

Dr. Pringle recommended a method of curing the lues venerea, which at first was brought into a regular practice by baron Van Swieten. His method consisted in giving corrosive sublimate in French brandy or molasses spirits. The proportion was a grain of the mercury to two ounces of the spirits; and his common dose was from half an ounce to an ounce, or, which is the same thing, from one spoonful to two, twice a day; adjusting the quantity to the strength of the patient and to the virulence of the disease. The operation was either by sweat or urine, especially when the medicine proved most successful. It was continued as long as any of the symptoms remained, with a low, spare diet, plenty of barley-water, and a little milk, or some such diluting liquor.

Of the Yaws.

THE Yaws is a distemper endemic to Guinea and the hotter climates in Africa; but has of late spread by infection over many parts of Europe. All are liable to it, but more especially in childhood or youth.

It makes its first appearance in little spots on the cuticle, not bigger than a pin's point, which increase daily, and become protuberant like pimples. Soon after, the cuticle frets off; and then, instead of pus or ichor, there appear white sloughs or fordes, under which is a small red fungus. These increase gradually, some to the size of a small wood-strawberry, others to that of a raspberry, others again exceed the largest mulberry, which in shape they very much resemble. In the mean time, the black hair in the yaws turn to a transparent white.

It is not an easy matter to determine the exact time which the yaws take in going through their different stadia. Lusty well-fed negroes have had several yaws as big as a mulberry in a month's time; whereas the low in flesh, with a scanty allowance, have passed three months, without their growing to the size of a strawberry.

The yaws appear in all parts of the body, but they are most plentiful and of the largest size about the groin, privy-parts, anus, arm-pits, and face. They are largest when fewest in number, and *vice versa*. They are not painful unless handled roughly, nor cause a loss of appetite. They continue long without any sensible alteration; and whether they would not in time, when the peccant matter is exhausted through the skin, vanish of themselves; or turn to corrosive ulcers, and affect the bones with nodes, exostoses, and caries; or, by enlarging the excretory ducts of the milary glands, cause a fluid to transude more viscid than sweat, which by drying on the skin would render the patient scorbatic, scabby, or leprous; is hard to say. It is an infectious disease.

The yaws are not dangerous, if the cure is skillfully managed at a proper time; but if the patient has been once salivated, or has taken any quantity of mercury, and his skin once cleared thereby, the cure will be very difficult, if not impracticable.

The negroes who have been cured in Africa never have them again in America.

As soon as the yaws begin to appear on a negroe, he must be removed to a house by himself; or, if it is not certain whether the eruption is the yaws or not, shut him up seven days, and look on him again, as the Jews were commanded to do with their lepers, and in that time you may be commonly certain.

As soon as you are convinced that it is the yaws, Take a scruple of flowers of sulphur; five grains of camphorated spirit of wine; a dram of Andromachus's treacle; and a sufficient quantity of Syrup of saffron. Make them into a bolus, to be taken at bed-time.

Repeat this bolus every night for a fortnight or three weeks, or till the yaws come to the height; that is, when they neither increase in size or number: Then throw your patient into a gentle salivation with calomel given in small doses, without farther preparation; five grains repeated once, twice, or thrice a-day, is sufficient, as the patient can bear it. If he spits a quart in twenty-four hours, it is enough. Generally, when the salivation is at this height, all the yaws are covered with a dry scaly crust, or scab; which, if numerous, look terribly. These fall off daily in small white scales, and in ten or twelve days leave the skin smooth and clean. Then the calomel may be omitted, and the salivation permitted to go off of itself. A dram of corrosive sublimate dissolved in an ounce of rum or brandy, and the solution daubed on the yaws, will clear the skin in two days time. After the salivation, sweat the patient twice or thrice.

He may likewise drink the decoction of guaiacum and sassafras fermented with molasses, for his constant drink.

Sometimes there remains one large yaw, high and knobbed, red and moist; this is called the master-yaw. This must be consumed an eighth or a tenth part of an inch below the skin, with equal parts of corrosive mercury and burnt alum, and digested with an ounce of yellow basilicon and a dram of corrosive mercury, and cicatrized with lint pressed out of spirits of wine, and with the vitriol stone.

To children under six or seven years old, at the proper time of salivating, [when the yaws are come to their full growth,] give a grain or two of calomel in white sugar, once a-day, one in two days, or once in three days, so as only to keep their mouths a little sore till the yaws dry, and, falling off in white scales, leave the skin clean. This succeeds always, but requires a longer time than in adults.

The venereal disease and the yaws seem to be very distinct distempers; but the symptoms, in consequence of the yaws ill cured, coincide so exactly with the symptoms of an inveterate French pox, that in most cases it will be very difficult if not impossible to distinguish them.

Of the SCROPHULA, or King's Evil.

THE King's evil is attended with hard, scirrhous, and often

often indolent tumours, which arise by degrees in the glands of the neck, under the chin, armpits, groin, ham, arms, and wrists; but it is most commonly seated in the neck, and beneath the ears.

Likewise cold tumours, which appear on the joints and bones, as on the knees, elbows, hands, and feet, but more particularly on the fingers, are disorders of the serophulous kind: as also the greatest part of those obstinate fluxions, which fall gradually on the joints, without a manifest cause; and which are attended with an abscess, a caries, and swelling of the bones, called the *spina ventosa*; especially of the apophyses and epiphyses. Of the same kind are likewise the pedemata or white swellings which arise in the arms, legs, and feet, principally about the joints. They consist of a jelly or coagulated lymph, which puffs them up, but do not pit when pressed with the fingers like dropical swellings.

In the eyes the serophula creates inflammations; in the eye-lids a puffing up of their edges with great soreness and small ulcers; in the angles of the eye a fistula lachrymalis, by ulcerating the gland planted there for the percolation of tears; in the lips, excessive and preternatural thickness; in the nose it often creates the crusty ulcer called *ozæna*. All which, except the last, are often the forerunners of this disease, antecedent to the great swellings and foul ulcers which appear in its maturer state.

The glands of the external parts are not alone attacked with this disease; for those of the mesentery are almost always affected; which appears from the opening of persons dying of this disease. Sometimes the disease begins in the mesentery; and sometimes the liver, spleen, womb, lungs, windpipe, brain, and other internal parts, are serophulous: Hence scirrhus tumours, incurable cancers, obstinate fluxions, rebellious ophthalmies, malignant abscesses, fistulous ulcers, dangerous quinleys, terrible epilepsies, mortal consumptions of the lungs, stubborn jaundices, dropsies, cholics, hypochondriac and hysteric affections.

The serophulæ are hard tumours, because they are produced by a thick coagulated matter; they are cold, because they are caused by a stagnation of the lymph in the part affected.

The serophulæ may be said to be benign, when they are superficial; when they do not much raise the skin, nor change its colour; when only the glands are puffed up, and are soft, moveable, without adhesion and indolent.

The malignant serophulæ are evident from the largeness of the tumour, its hardness and adhesion; from its becoming livid or red; from its being painful; and, when ulcerated, from the callosity of the lips of the ulcer, and from their difficult cure.

As to the prognostics; the benign serophulæ admit of an easy cure, especially if they are seated in the conglobate glands, and are moveable, superficial, and soft. Those which attack the joints, the tendons, the ligaments, the bones, which are near large vessels, or compress the *aspiræ arteria*, or the oesophagus, are very difficult to cure. The internal serophulæ are much more dangerous than the external; for when they turn to an abscess, they are incurable. They are also more or less troublesome in proportion to the progress they have made, the parts which they attack, and the temperament of the patient. If the strumæ have been long ulcerated, and are become sinous and vi-

ruent, and if they lie near one another, they often find a communication, though they appear distinct: In this case the lips grow callous, and the ulcers corrosive, frequently ffordid; and the cure is not to be expected as long as one cyllis remains of the vessels that feed them. Those who are seized with strumæ in the neck after forty years of age, seldom recover.

If strumous tumours arise from a caries in the bones of the fingers or hands, the cure is difficult; but more so in the feet and toes. If in the os calcis, joint of the ankle, or astragalus, or in the knee-bones, or ilchia, or the like, where they cannot be safely laid open, the case is deplorable, and the patient generally dies of a marasmus.

In the cure, the diet should be thin and attenuating, light and easy of digestion; and all salt and smoke dried meat should be carefully avoided; as also beef, pork, fish, hare, cheefe, and in general all things that are hard of digestion, or which yield indifferent nourishment. The air should be pure, sweet, and dry; and the body should be kept always open.

The cure may be begun by bleeding, especially if the patient is plethoric, and then a mercurial or antimonial vomit; after which he should take a gentle purge, often repeated, such as the common purging potion of Sydenham; and, as almost all remedies which are good in venereal cafes are useful in this, mercurial vomits and purgatives will be proper.

Some give ethiops mineral alone for three months; beginning with twelve grains, and increasing the dose gradually to a scruple, or half a dram, and decreasing in the same manner.

It is certain that the united force of mercurials and antimonials will do wonders in these cafes, if prudently given and long continued; always beginning with small doses at first.

Some make use of the decoction of sponge; the dose is four ounces: others, burnt or calcined sponge; the dose is half a dram morning and evening. Turner mentions a cure from an electuary made of the most gritty and fabulous sponges that could be got, which were dried in an oven so much as to be fit to pulverize. The dose was a spoonful night and morning.

Others recommend the absorbent powders and diaphoretic antimony; others again, tincture of antimony in a glass of the decoction of the woods; Dr Francis Fuller, the decoction of colts-foot used for a long time. Fallopius praises the root of butchers-broom; the dose is a dram with x. gr. of the root of common flower-de-luce. *Ann. de Villanova* looks on the root of serophularia or figwort as a specific; the dose is a scruple in powder. And Allen mentions two cures performed by white archange, boiled in milk, which it coagulates; the whey of which must be drank, and the curd applied to the sores. Of late the mineral waters of Moffat in Annandale have been drank with great advantage.

Epsum salt dissolved in a pint of water in such a quantity as to keep the body open, and taken like sea water, has often cured this disease.

After all, we have another medicine whose virtues in curing this disease have been lately celebrated, viz. the j-suits bark.

1. Take of the best rhubarb, half an ounce; of Florence

rentice orris, an ounce; of dried red roses, a dram and a half. Infuse these, after they have been cut and bruised, in two quarts of small ale; and let the patient drink a glass of the colature twice a day, with the quantity of a nutmeg of the following electuary:

1. Take of the powder of the Peruvian bark, six drams; of Salsaparilla bark in powder, two ounces. Make them into an electuary with a sufficient quantity of the syrup of sugar.

Dr Fothergill has likewise long given the bark in scrophulous disorders, and affirms that it may not only be given with safety, but to manifest advantage in many of these cases.

He gives the bark in a liquid form, in the following manner:

3. Take of Peruvian bark in powder, an ounce; and boil it in a quart of pure water to a pint. Towards the end, add of sliced liquorice-root half an ounce. To the colature add of nutmeg-water two ounces, and mix them. The dose is two, three, or four spoonfuls, with ten, twenty, to forty drops of the volatile tincture of guaiacum, twice or thrice in a day.

A small quantity of winter's bark, added to this medicine, gives it a grateful warmth, and renders a quantity of the compound water less necessary; and a little liquorice, a few raisins, gum arabic, or the like, added to the decoction before it is taken off the fire, by making the liquor viscid, enables it to suspend more of the fine particles of the bark, and at the same time renders it less disagreeable.

The swellings of the joints, commonly called white-swellings, are of the strumous kind, and of two sorts; they are both made by congestion, and increase gradually; the one arises externally upon the tendons, and between them and the skin, or between them and the bone; the other internally, within the bone itself.

That which arises externally affects the ligaments and tendons first; and sometimes relaxes them to such a degree, that the heads of the joints frequently separate one from another, and the member wastes away and grows useless. But most commonly the humours, by over-moistening the ligaments and tendons, produce a weakness and uneasiness in the joints, raising a tumour externally, and, in its progress, the membranes and bones are corroded by the humour. It will be more certain that the tumour is the offspring of the king's evil, if there are strumous symptoms in any other part of the body.

In order to the cure, in the beginning of the fluxion, apply astringent and drying plasters of red lead and bole, with moderate bandage, and place the member in such a position as may prevent the descent of the humours. The internal remedies may be the same as in the general cure. Cheyne and Allen say, water pumped on the tumour is a certain remedy.

Of the Cancer.

A **CANCER** is a hard, round, unequal, painful, and generally immovable tumour, of a livid, blackish, or leaden colour, surrounded with swelled, crooked, varicose ves-

sels, in some sort resembling the feet of a crab, from whence this tumour takes its name.

A cancer is either occult or manifest. An occult begins at first with a small and almost indolent tumour, about the size of a pea, or a hazel-nut, which does not change the colour of the skin, and sometimes lies dormant for several years without making any progress.

But as soon as the virulent humour begins to become more active, the small tubercle becomes all of a sudden a large, round, livid tumour, with an unequal superficies. It is generally attended with an intense shooting pain. At length it begins to eat and break through the skin, and so becomes a manifest or ulcerated cancer, from whence proceeds a fœtid, viscid, bloody, sanious or ichorous matter, attended with an insupportable stench.

Though a cancer may infest any part of the body, it generally appears in the breasts, armpits, behind the ears, in the lips, nose, and private parts: women are more subject to them than men. Its general seat is the glands, and is a-kin to a scirrhus.

An occult cancer is known to be formed, when, after the signs of a preceding scirrhus, a titillation, itching, heat, redness, are gradually perceived, with a shooting, burning, pricking pain. The colour of the skin likewise changes from a carnation to a deep red; then it becomes purple, bluish, livid, and at length black: The part feels very hard, unequal, and rough; then it rises with an apex in the middle; the swelling increases, and the adjacent veins become tumid, knotty, varicose, thick, and black.

When it begins to break, the skin is excoriated, and there transudes through it a thin sharp ichor.

After this the sound vessels on the edges of the cancer, being distended by the rising of the tumour, are broken; hence arises a putrefaction, which turns into a subtil, sharp, fetid, cadaverous sanies, which, corroding and eating away the sound parts, makes a progress in depth as well as in circumference, and sends forth malignant roots, by which it takes fast hold; the lips become tumid, parched, and offensive to the sight; the pain is intolerable, with a sense of burning, pricking, and gnawing; the colour becomes cineritious, livid and black. Afterwards arise occult cancers communicating with the glands; hæmorrhages; convulsions; a slow fever; a general wasting; loss of smell; callous tubercles in the ears without pain; fainting fits. The parts being thus eaten away and consumed, death ensues.

In persons of a good habit, an occult cancer may be pretty easily borne; but if it be disturbed, the preceding ravage must be expected.

A small, incipient, free cancer, seated in a suitable place, not joining to large vessels, arising from an external cause, in a juvenile, sound body, and being the only one in the body, should be extirpated without delay.

Outward applications of all kinds, except the plumbous and narcotic, are to be shunned, because they have a tendency to ulcerate an occult cancer.

If the cancer be large, old, adherent, in a place unapt for extirpation, growing to or lying upon large vessels arising

arising from an internal cause; and the patient being old, disposed to these kind of disorders, and having more than one; neither excision nor topics are proper.

For unless it be extirpated, root, branch, and seed, it will be exasperated, and strike inwards, generate others, and increase those already formed.

The cause of a cancer must be taken away with it, or before an attempt of that kind is made.

A cancer of the fauces, palate, armpits, or groin, is incurable; of the lips is hard to cure.

When a cancer is large, &c. as above-mentioned, all we can do is to leave it at rest, and to appease the symptoms.

The first point is obtained by defending it from external injuries, by applications consisting of plumbeous ingredients and narcotics; by diminishing and correcting the cause. For this purpose cathartics with mercurials in a small, and sometimes in a double dose, will be proper; as also diluents, aperients, and subalkalious remedies; taking care not in any manner to increase the cause.

When the cancer is ulcerated, if it cannot be taken off, it should be kept as clean as possible, and be appeased with the most soft saturnine applications.

Mr Gataker has found, that the solanum hortense, as well as the lethal, otherwise called belladonna, has had surprising effects in the cure of obstinate pains, ulcers without malignity, scorbutic eruptions, and even cancerous ulcers of the face, and scrophulous sores on the thighs. Junker affirms belladonna has cured a most deplorable cancer of the breast. The dose of either is a grain or two at night going to bed, which sometimes makes the patient giddy at first. Three will often vomit, sweat, or purge the patient moderately. Boiling water must be poured upon the herb, which must be afterwards squeezed out.

Of the ELEPHANTIASIS, or Leprosy of the Arabians.

THE leprosy is said to be of two kinds; that of the Greeks, and that of the Arabians. The latter is called elephantiasis, from the roughness, inequalities, and tubercles in the skin, resembling that of an elephant. Lucretius supposed it to be generated in Egypt, and no where else; but if the leprosy of the Jews is the same as that of the negroes, which is highly probable, then we may affirm that it is endemic to the Southern and inland parts of Africa.

That it was contagious, all histories agree, as well as far as profane; and the Persians would not let a leprous person come within the city-walls.

Pliny informs us, that the first appearance of the elephantiasis is in the face, particularly a small speck appears on the nose or nostril; and, as the disease increases, the whole body is full of spots of various colours; the skin is thick in one place, and thin in another, hard and rough, with scabs. In process of time, the skin turns black, and the disease eats away the flesh to the very bones. Celsus observes, that the spots grow tumid and red, and then turn black, and the skin is covered, as it were, with scales. Then the body falls away, the mouth, legs, and feet swell, and the fingers and toes are hid with a swelling; even the bones themselves do not escape; afterwards a fever arises, to which the patient falls an easy victim.

But to set this matter in a still clearer light, it will be

necessary to add the description of this disease from *Guido de Chauliari*. The leprosy, says he, commonly begins in the face and forehead, in which filthy tubercles make their appearance, and by degrees spread all over the body. The eyebrows swell; the nostrils grow wider outwardly, and straiter inwardly; the lips are disfigured with an unsightly tumour; the voice is hoarse and snuffling; the ears are turned back; the forehead is protuberant; the face is of a purple colour; the veins under the tongue are varicose and black; the muscles between the fore-finger and the thumb are eaten away; the hair falls off from the head and eyebrows; afterwards the skin of the whole body becomes black and full of spots, rough and unequal, with crusty scabs full of knobs and fissures, of horrible aspect, which makes it appear like the skin of an elephant. After this, the fingers and toes begin to swell; and then the legs, which, being covered with rugged inequalities, seem like two sacks for magnitude. Besides all this, the patient is insatiable with regard to venereal pleasures. The blood is fetid, spotted and black, and will not coagulate.

This disease is hereditary and infectious: for it may be caught by the saliva of a leper, if a sound person drinks after him; by touch; by lying in the same bed; and by coition.

An inveterate leprosy was judged to be absolutely incurable. But Aretæus says, when the disease is new and recent, there are hopes of a cure. What he and Celsus prescribe in order to the cure, are not worth repeating; for, if any medicines will do, they must be of the Herculean kind. Authors are excessive in the praise of viper's flesh, which Hoffman judges to be quite insignificant. Joel advises bleeding and purging, with xij grains of the extract of black hellebore, or iij gr. of the glass of antimony in conserve of roses; but the vitrum ceratum is more safe, and may be given in a larger dose. Towne confesses, that antimonial preparations yielded most relief in Barbadoes; but he could not say that they perfected the cure. On the other hand, mercury exasperated the distemper, irritated the ulcers, and made them spread the faster.

Of the IMPETIGO, or Leprosy of the Greeks.

THIS distemper begins with red pimples or pustules breaking out in various parts of the body; sometimes they appear single; sometimes a great number arise together, especially on the arms and legs: as the disease increases, fresh pimples appear, which joining the former make a sort of clusters, all which enlarge their borders and spread in an orbicular form. The superfluous of these pustules are rough, whitish, and scaly: when they are scratched, the scales fall off; upon which a thin ichor oozes out, which soon dries and hardens into a scaly crust.

These clusters of pustules are, at first, small and few, that is, three or four in an arm, or leg only, and of the size of a silver penny. But, if the disease is suffered to increase, they become more numerous, and the clusters enlarge their circumference to the bigness of a crown-piece, but not exactly round. Afterwards it gradually increases in such a manner that the whole body is covered with a leprous scurf.

Willis blames all dried and salted meats, especially hog's flesh; and fish, particularly shell-fish, because the poor people in Cornwall, inhabiting near the sea coast, were formerly much subject to leprous diseases, and had many hospitals erected on that account.

In the method of cure, says Hoffman, we should endeavour to discharge out of the body the mafs of corrupt, glutinous, and acrid humours; by sufficient bleeding and abstinence, and by purges, as well gentle as drastic; then, by proper aliment and a good regimen, promote the generation of wholesome juices; and, likewise by external, detensive, consolidating, and drying remedies, to free the parts from pains, tumours, itching, and ulcers.

The purges may consist of the root and the resin of jalap, the extract of black hellebore, elaterium mixed with calomel, or ethiops mineral, and gum ammoniac.

Among those things which stimulate the solid parts to an excretory motion, and more powerfully melt down the tenacious humours, the lignum and cortex guaiac. exceed all others, as they will generally alone cure the lues venerea. The most considerable, besides these, are the tartarized and acrid tincture of antimony, sulphur of antimony, cinnabar, and, if a venereal taint is suspected, a decoction of crude antimony. Which medicines, in a convenient dose, in the morning, with purifying decoctions drank in bed, afford very great relief.

But, if these fail, recourse must be had to mercury, which some, after extinction, mix with flowers of sulphur and camphor, and rub it on the joints to promote a salivation: others more properly give mercurius dulcis, with double the quantity of crabs-eyes and calx of antimony, rising gradually from three or four grains to a scruple, in order to salivate; with the usual precautions. The cure may also be performed with alterative and diaphoretic preparations of mercury, such as mercurius solaris and jovialis; of which a few grains may be exhibited every morning in conserve of roses for some weeks, drinking in bed after it a pint of some proper decoction.

But it must be observed, that each of these methods of cure requires an air very temperate, a spare thin diet, and an abstinence from fat, and boiled flesh, and acids.

Of the Itch.

THE itch is a cutaneous disease, arising from a corruption of a ferous lymphatic matter, sometimes attended with mild, sometimes with more obfinate and dangerous symptoms. The itch of the milder sort appears either with moist or dry pustules, at first about the joints, and from thence spreads by degrees over all the body, the head only excepted. In the moist sort, to which children and the sanguineo-phlegmatic are most subject, the pustules are more full of a purulent matter, attended with a slight inflammation, which is manifest from the redness which appears round about them till it suppurates. The dry sort chiefly attacks those that are lean, old, or are of a melancholico-choleeric constitution: In these, the pustules are much less, and excite a most intolerable itching, especially in the night-time. The most usual places where the eruptions appear very numerous, and the itching is greatest, are between the fingers, on the arms, hams, and thighs.

This disease is, truly and properly speaking, a disease of the skin; because it often is safely cured by topics alone, if timely applied. It is contagious, and may be caught by drawing on a glove or stocking, wiping on the linen, or lying in sheets after persons infected with this malady. Some think it owing to an impurity in the serum, and some to animalcule. But however that be, it often affects such who have been long kept in prison, who lead inactive lives, and are used to live in a stutish nasty manner, or who constantly eat fish or flesh dried in the smoke or sun, and use any other unwholesome food or drinks; or who live in a cold, moist, and cloudy air, which, hindering a free perspiration, causes a stagnation of humours in the superficies of the body, which are for that reason liable to corrupt.

The milder sort of itch is no way dangerous, and very easy to cure; but the moist more easy than the dry. While it is recent and superficial, it much sooner yields to remedies, than when it is deep, and has infected the mafs of blood; and the case is still worse, if there be any fault in the viscera: it is more difficult in old persons than young; in a leuco-phlegmatic or hydropical disposition, as also in a very dry hectic one, it is hard to cure; and, when it becomes universal, it may bring on the leprosy.

The patient should avoid shell-fish, and all salted and high seasoned meats; as also wine, spiritous liquors, strong beer, and every thing else that may inflame the blood. For this reason a slender diet is best, unless perspiration be obstructed.

If the body is plethoric, we are to begin by bleeding, and afterwards to pursue it by purging, which cannot safely be omitted.

Instead of repeating purging, it is common to give flowers of sulphur in milk, or treacle, with good success.

Willis and many others have a great opinion of the efficacy of sulphur used both internally and externally; to which Turner assents, except in hectic and consumptive cases. But Shaw thinks it is not to be depended on when outwardly used. Yet it is very certain that poor people find a great deal of benefit who drink it inwardly with milk, and use it outwardly with butter, or hog's-lard.

Turner prefers the salt of tartar to most other remedies, it thoroughly purging and cleansing the blood taken inwardly, and, made into a lixivium with spring water, is an excellent wash outwardly.

When the blood is thought to be foul, it will be proper to use diet drinks, through the whole course, of the roots of china, sarsaparilla, oxylapathum, scorzonera, chichoreum, glycyrrhiza, polypodium, the barks of saffras, cinnamonum, the shavings of the woods of saffras, and the like; which will strengthen the solid parts, and dry up superfluous humidities.

It has been a very common practice to cure the itch by quicksilver girdles; but Turner thinks them too hazardous to be brought into regular practice, and Shaw seems to be of the same opinion.

But after all this, if the disease should prove so stubborn as not to give way to the most powerful of the preceding methods, recourse must be had to salivation as the dernier resort, which will prove effectual when every thing else fails; which, however, is not to be made use of till

the case is so desperate as to render it absolutely necessary.

Of HÆMORRHAGES in general.

THE blood, which flows spontaneously, generally proceeds from those places which are of a fine and thin texture, in whose surface the slender vessels creep along with various meanders; such as the inward part of the nostrils, the bronchia of the lungs, the flesh of the gums, the left side of the stomach, the gut ilium, and the extremities of the rectum, as also the external substance of the womb and vagina. When these parts are distended, and the small arteries open, the blood often breaks out with violence.

Sometimes, though but seldom, hæmorrhages happen in other places where the vessels lie deeper; as from the little finger, from the hand and knee, the breasts in the time of menstruation. There are likewise instances of periodical fluxes from the penis in men.

They generally happen to persons whose bodies are of a soft, spongy, tender texture, and whose vessels are turgid with blood and serum. These were formerly said to be of a sanguine constitution, and are subject to hæmorrhages as long as they live. But the choleric, who have larger vessels, whose fibres are more strongly braced, and whose blood circulates with greater rapidity, are liable to a spitting of blood in their youth. The sanguineo-melancholic are subject to the bleeding piles; and women who are sanguineo-phlegmatic, are obnoxious to vomiting blood.

Boys and youths are most subject to bleed at the nose; in young men the blood seeks an exit from the lungs, whence hæmoptoes and consumptions; the middle-aged are more liable to hæmorrhoidal evacuations, and decrepid old men to pissing of blood.

Hæmorrhages are most frequent at the spring and fall; hence sanguineous apoplexies at those seasons, which are nothing else but eruptions of the blood in the middle of the brain. Vomiting and pissing of blood are more frequent in the autumn. In some, these excretions happen periodically.

When hæmorrhages proceed from a fulness of the vessels, they conduce to the preservation of health; but when they are caused by a poisonous acrid matter, as in malignant and spotted fevers, they are exceeding dangerous. Also when they are derived from an infection, induration, and corruption of the viscera, especially of the liver, spleen, or lungs, they are generally fatal, because they bring on a cachexy, dropsy, the black disease of Hippocrates, and a mortal hectic.

Of BLEEDING at the Nose.

A HÆMORRHAGE at the nose is owing to the more plentiful supply of blood to the nostrils by a strange motion of the heart, whereby the small arteries in the pituitary coat become turgid, and too much distended, till at length they gape, and the blood rushes out.

A bleeding of the nose may be promoted when persons of sedentary lives that indulge their appetites, and so become plethoric, put their blood into extraordinary agitation by violent passions and exercise, by spirituous liquors,

spices, heating volatile medicines, hot baths, or suddenly chilling their feet.

Likewise the sudden change of air from hot to cold, and cold to hot, by fits, especially at the equinoxes, may cause this bleeding; as also when from cold and moist the air becomes highly elastic, and *vice versa*. Those, moreover, are liable to it who are afflicted with rheumatic, nephritic, arthritic, and ischiadic pains, or who have fevers or spasms. It sometimes happens before the eruptions of the small pox and measles, and to those who have lost a large limb, or who labour under obstructions of the liver and spleen; hence, in an inveterate scurvy, dropsy, and cachexy, there often happens a fatal hæmorrhage.

It differs much as to the quantity; some lose only a few drops, some several ounces, and some five or six pounds. No hæmorrhage is more apt to return; which it does to some in a few days, to others in a few hours.

To the plethoric it is generally salutary; and there are many instances of a vertigo, a scotomia, dull heavy pains of the head, a phrenzy, and even an epilepsy, being carried off by a bleeding at the nose. On the contrary, from its suppression there have arisen vertigos, apoplexies, epilepsies, convulsions, noise in the ears, and hardness of hearing, and even a gutta serena.

These hæmorrhages are critical and salutary in a synochus on a semicritical day, that is, between the third and fourth, or on a critical day, *viz.* the seventh: for, as these fevers are generally caused by a plethora, they are carried off that way.

But enormous and long-continued bleedings at the nose, when they arise from spasms of the internal parts, and are preceded with coldness of the extreme parts, and fainting fits, generally terminate in death.

After a revulsion by bleeding, there is nothing equal to nitre to appease the orgasm of the blood, and to relax the spastic stricture. Next to these are vegetable acids; such as the juice of Seville oranges, barberries, the water and juice of wood-sorrel; but more especially the diluted spirit of vitriol, tincture of roses, made with the water of wood-sorrel and the spirit of vitriol, and drank with spring-water. [Five or six spoonfuls of the common tincture of roses may be given at a time, and repeated as occasion requires.]

If the bleeding is very inordinate, it will be proper to use cooling emulsions, gentle or stronger opiates to moderate the spastic strictures, as occasion shall require. Camphor, mixed with nitre and calx of antimony, will be highly necessary, if the matter of exanthemata or cutaneous eruptions is the cause of the hæmorrhage, as is often the case.

A revulsion may be made from the head, by bleeding in the lower parts; then by temperate pediluvia, and putting the hands into warm water.

As there is often an acrid bilious matter lodged in the hypochondria, the parent of wind and spasms, the powder of rhubarb will be proper, mixt with a few grains of tartarvitriolate and nitre; as also emollient and carminative clysters, with a due proportion of oil.

Externally, refrigerants may be mixed with discutients, and applied to the forehead, nose, and neck.

But

But it must be noted, that, when the patient is plethoric, the bleeding must not be stopped hastily, if at all; nor when the menses in women have been suppressed, or the lochia, or the bleeding piles in men accustomed thereto; much less must a stoppage be attempted when the bleeding itself is periodical.

In persons of a bilious constitution, cold water alone, drank freely, has had a good effect.

The cachectic should persist long, in the taking of rhubarb, either alone, or mixed with digestive salts, such as tartar-vitriolate. If there is any scorbutic disorder in the viscera, besides rhubarb, the patient should drink plentifully of whey.

If any disease proceeds from the cessation of this customary hæmorrhage, it should be promoted with a pen or a straw thrust into the nose.

Some recommend the weaker spirit of vitriol, and would have eight or ten drops of it be given in every draught of liquor. But perhaps the best method of all in obstinate hæmorrhages is that recommended by Mead in the bloody small-pox; or the Peruvian bark alone will generally be sufficient.

Of the Bleeding and Blind PILES.

A Flux of blood from the hæmorrhoidal vessels is called the bleeding piles; when the vessels only swell and discharge no blood, but are exceeding painful, they are termed the blind piles.

All copious fluxes of blood from the anus are not to be reckoned of the morbid kind. For the habit of body, strength, age, and temperament, are to be considered. That which is enormous and excessive to one person, may be moderate and salutary to another. That only is to be esteemed pernicious, which continues too long, and enfeebles the patient; whereby digestion, nutrition, and other functions are hurt, and there is reason to fear the production of dangerous chronic diseases.

An excessive hæmorrhoidal flux is generally preceded by a heavy pressing pain of the back and loins; sometimes a numbness of the legs and thighs; a constriction of the external parts, with a slight shivering, and a subsidence of the vessels therein; a hard contracted pulse; a dryness of the mouth and fauces; the urine diminished in quantity, and most commonly pale; a sense of weight about the anus extending to the perineum; a weakness of the stomach; a flatulency in the lower belly; a frequent desire to make water and to go to stool, with sometimes an exclusion of white bilious mucus; the old and weak have a proclivity to it.

In this case, the blood is generally at first black and very grumous, and sometimes comes away in large clots from the varicous vessels; afterwards it becomes red, and at last serous; sometimes it is pituitous, or like the white of an egg. There are instances of voiding a pint or a quart of blood daily; it often continues long, from twenty to thirty, or even forty days.

This flux entirely proceeds from the hæmorrhoidal vessels. The external or blind piles seldom bleed, but turn to painful varices; which being opened weep a little, but will not yield much blood. But the internal piles, which are the offspring of the splenic branch, and are extended

to the inner substance of the rectum, and as far as the sphincter of the anus, together with the small arteries derived from the lower mesaric, not only bleed plentifully, but, when the flux is suppressed, create diseases of the liver, spleen, pancreas, mesentery, and intestines.

The persons subject to this disease are those of a loose, spongy texture, of a bulky size, who live high, and lead a sedentary life; or to whom it is hereditary. Sharp purges, aloetics, high-seasoned food, free drinking of sweet wines, neglect of customary bleeding, anger, sadness, hard riding, and the like, will usher in this disorder.

This hæmorrhage is dangerous, because it decays the strength, wastes the body, and produces a sense of weight in the thighs. The sleep is laborious, and the præcordia oppressed; there is a rumbling in the belly, and a weak pulse. When it continues long, the ancles swell, and the countenance is ghastly; there is a straitness of breathing; and last of all it terminates in a cachexy, dropsy, or a slow and hectic fever.

If the patient is plethoric, bleed; and let his drink be cold water of the chalybeate kind, or whey turned with orange-juice; or juleps made with tincture of roses, cooling waters, and syrup of roses; likewise nitre in powder, with absorbents and strengtheners; and, to appease the spasms, opiates of the mildest kind.

If it continues long, and the flux begins to be serous, then give rhubarb with curants or tamarinds, or, which is much the same, with cream of tartar. Then gentle diaphoretics may be compounded of burnt hartshorn, calx of antimony, wine-vinegar mixed with crab's-eyes, water of elder-flowers, simple alexiterial water, and diascordium; or hot decoctions of yarrow, veronica, &c. may be taken in bed, in order to sweat; also half a grain of camphor, mixed with nitrous and bezoardic powders.

In the BLIND PILES there is a most intense pain, especially at the time of going to stool, and the excrements are tinged with blood. Sometimes tumours like warts lie hid in the sphincter, or appear in the verge of the anus.

Sometimes the veins, in the blind piles, are so much dilated with blood as to be very painful, and raise tubercles as large as peas, grapes, or eggs: They appear livid, and black, from the stagnation of a thick blood, and, when pressed with the fingers, feel like a bladder filled with liquor. Some are soft and indolent; others hard, inflamed, and painful; render the patient unable to walk, stand, or sit; and produce such a spasm in the anus as not to admit a clyster. Sometimes they bleed, or turn to troublesome itching ulcers, and occasion an abscess or a fistula.

Linen dipped in warm spirits of wine, and emollients, are often of infinite service; and, when they fail, leeches may be applied to exhaust the blood: If they are not at hand, and the parts are inflamed, the lancet must be used; then dressings must be made with lint, with compresses and the T bandage. The tubercles, which are full and large, may be removed by a ligature, unless inflamed. Sometimes they are high in the rectum; and then a speculum ani must be used; in which case they must be either scarified with a lancet, or divided with scissars, that the thick noxious blood may be discharged, and the pains relieved.

Of the Immoderate FLUX of the MENSES.

THE symptoms which attend this disorder, are loss of strength, anxiety of the præcordia, fainting, coldness of the extreme parts, paleness, convulsions, suffocations; and, when it is inveterate, oedematous swellings of the feet, a cachexy, dropsy, the fluor albus, a hectic fever, and an atrophy.

Sometimes the flux returns twice in a month; and at others continues several days longer than usual. It comes sometimes before and sometimes after abortion. Sometimes florid blood rushes out with impetuosity, most frequently before a miscarriage, and after it from a retention of part of the after birth, which keeps the orifices of the vessels open. Sometimes clots of blood come away of the size of an egg, when the menses have been stopped for two or three months. A black, grumous, coagulated blood will now and then come away on the first days of child bed, when the patient is slender and plethoric. In the cachectic, the flux will be often thin and watery; in the scorbutic corrupt and fetid, attended with sharpness and pain.

It is sometimes caused by a great afflux of blood to the uterus, which is not returned in due quantity by the veins; for which reason the vessels often burst. The same happens from a plethora, and from hard labour. About the fiftieth year, when the menses cease spontaneously, a great and sometimes dangerous flux will happen, and then quite disappears. If it should suddenly and unexpectedly return about sixty, with flooding, it brings on a fatal hectic fever.

This disease is generally preceded and accompanied with a tension and inflation of the hypochondria; a heavy, pressing pain about the loins, with a chinefs; as also a coldness of the extreme parts, a subsidence of the vessels, a paleness, a quick pulse, an inward heat, a costiveness, and little urine.

If a child-bed woman is not sufficiently cleansed at her lying-in, a great hæmorrhage will follow some months after, with fainting fits, and will not terminate till the excretion of a carnosous mass as big as one's fist, which the sex call a mole.

If the body is cacochymic, and full of depraved juices; scorbutic, or infected with the venereal lues; when the viscera are unsound, and the liver, spleen, and meseraic vessels are stuffed with a black, thick blood; this disease is not without danger. The patient's life is greatly in danger when the child is dead before delivery, and a great flux of blood happens. It is dangerous when caused by a violent extraction of the after-birth; or when pieces of it are left behind, which afterwards become moles, and greatly vitiate and increase the menstrual flux.

If the patient is plethoric, bleed in the arm. If there is an orgasm in the blood, diluents, humectants, and refrigerants, will be most efficacious: in this case spring-water may be drank alone, or with a little nitre, or with spirit of vitriol and syrup of poppies; the spasms require gentle opiates. To carry off the impure serum, two ounces at least of manna must be given, with a dram of cream of

tartar in an aqueous vehicle. If the flux is obstinate, recourse must be had to altringents.

Thomson of Montrose recommends an improvement of Helvetius's styptic powder; which consists of two parts of crude alum, and one of dragon's blood; whereas Thomson's is equal parts of each; and the alum is to be burnt in a crucible, and the dragon's blood added to it, and afterwards powdered. Mead has three parts of burnt alum to one of dragon's blood.

He says he never found this medicine fail in uterine hæmorrhages, whether to correct the too frequent return of the menses, or their too great abundance, or to stop the flooding of women with child, or to moderate the flux of the lochia.

The quantities which he gives are more or less, according to the exigencies of the patient. In violent bleedings, half a dram every hour; and three drams or half an ounce seldom or never fail to stop the flux.

Of a Hæmorrhage from the Urinary passages.

THIS disorder is commonly called pissing of blood; and is an emission of blood with or without urine, from the vessels of the kidneys or bladder, which may be either enlarged, broken, or eroded. It is more or less dangerous, according to the different circumstances which attend it.

If pure blood is voided suddenly without interruption and without pain, we may conclude it proceeds from the kidneys. It likewise comes from the kidneys, if the urine is coffee-coloured or more florid, and generally precedes a fit of the gravel, but sometimes accompanies the passage of a stone through the ureters. But if the blood is small in quantity, and of a dark colour, with or without purulent matter, chiefly if it is emitted with heat and pain in the pubes, it certainly proceeds from the bladder. This is sometimes attended with fainting, difficult breathing, a slow, small, and frequent pulse, a nausea, anxiety, and cold sweats.

When it proceeds from the ureters, which are hurt by a large, rough stone, and a small quantity of blood is mixed with the urine, there is a sharp pain in the loins and ilia, and a difficulty of making water, which when made has a fabulous sediment, and other signs of a stone sticking in the ureter. When the coats of the bladder are hurt by a stone, and a little blood follows, it is attended with a most acute pain and a previous stoppage of the urine, together with grumes and fabulous concretions; which also sometimes happens when a stone is firmly fixed in the kidney.

It may be occasioned by a stoppage of the hæmorrhoidal flux; from violent motion of the body, especially riding; from a stone concealed in the kidney: from an erosion and ulcers of the bladder; from external violence; from gripping pains caused by violent purges; from sharp diuretics, especially cantharides.

All bloody urine has some degree of danger; but it is most so when mixed with purulent matter.

If the patient is plethoric, or if it proceeds from the suppression of a sanguineous evacuation, bleeding is necessary; as also cooling nitrous draughts, and purified nitre mixed with absorbents, with whey for a vehicle, or barley-

water,

water, or small-beer, acidulated with some drops of the spirit of vitriol. The body must be kept open with laxatives, as rhubarb with currants, or with cream of tartar; as also emollient clysters. The relaxed vessels must be agglutinated with decoctions of vulnerary herbs; such as agrimony, ground-ivy, yarrow, golden-rod, and the roots of comfrey dulcified with virgin-honey, to which milk may be occasionally added. Almond milk is likewise good, especially if used as a vehicle with bole-armenic.

If there is an ulcer in the kidneys or bladder, medicines must be given that sheathe the acrimony; such as syrup of marshmallows; also infusions of the vulnerary herbs above mentioned; likewise of the bark of the roots of acacia and cherry tree gum.

When grumous blood plugs up the passage of the ureters into the bladder, or the sphincter of the bladder, and occasions a difficulty or stoppage of urine, warm water drank plentifully, and baths of the same, are useful; likewise warm water should be injected into the bladder with a syringe, that the sharp humour may be diluted and the grumes dissolved. But, if the urine should be quite stopped with a spasm, then give emulsions of the four cold seeds, with crab's-eyes and calx of antimony; or a powder made of sperma ceti, crab's-eyes, and nitre. Externally, apply a bladder filled with the decoction of emollient flowers in milk to the abdomen; and keep the body open with manna, or an emollient oily clyster.

Milk and whey are likewise excellent in these disorders, if a dram of bole armenic is taken in every draught.

Of the LETHARGY, CARUS, and other sleepy diseases.

THE lethargy has some affinity to the apoplexy and palsy, and often attends them.

By sleepy diseases are meant a preternatural propensity to sleep, sometimes attended with, and sometimes without a fever: The immediate cause of which is a very languid and diminished influx of the animal spirits from the cortical part of the brain into the medulla oblongata, and from thence into the nerves destined for sense and motion.

There are several kinds of these disorders, the principal of which are a coma vigil, a coma somnolentum, a carus, and a lethargy.

A coma vigil is known by these signs: a burning and extensive pain in the head, attended with a sense of ebullition therein; they have a strong inclination to sleep, and yet either don't sleep at all, or, if they do, awake immediately with little relief, but have no delirium. This coma differs from the pervigilium, which is frequent in acute fevers, for in this there is no propensity to sleep. This disorder is always symptomatic, and often attends acute, burning, and malignant fevers; as also an inflammation of the dura mater, and others in a pnenfy.

In a coma somnolentum, the patients are languid, and their chief complaint is a constant drowsiness. They often fall asleep at their meals, in conversation, and in the midst of business, and, when they are awakened, soon fall asleep again. This disorder principally seizes old men, who live luxuriously, and neglect bleeding. It is a primary disease, and without a fever.

A carus is a profound sleep, out of which the patient cannot be roused by clamours, shaking, nor even with the

pricking of a needle; or, if they are sensible of the pain, they continue silent, and fall asleep again. It is sometimes a primary disease, and sometimes symptomatic. When it is symptomatic, it is of three kinds: The first happens in acute fevers, in the beginning or increase; and, if the convulsions and hiccups supervene, it is soon fatal. The second comes after acute fevers; and, when the patient is exceeding weak, the sleep will continue for several days; being awaked, he will answer questions, but immediately fall asleep again. When he recovers, he remembers nothing that he said. If it happens in acute fevers, on critical days, with a sweat, it is a good omen. The third happens a day or two before death: for, the patient's strength being exhausted, he lies deprived of sense and motion, as it were in a profound sleep, and under that expires.

A lethargy is a heavy and perpetual sleep, with scarce any intervals of waking. It is attended with a stupidity, and so surprising a forgetfulness, that, when the patient yawns, he forgets to shut his mouth; or, if he takes the chamber-pot to make water, he forgets to do it, and falls asleep.

A lethargy is attended with a fever, which is a symptom thereof, and is chiefly discovered by the frequency of the pulse; whereas a carus is often a symptom or a consequence of a fever, and is likewise attended with insensibility. It does not invade so suddenly as an apoplexy, which is attended with an abolition of all sense and voluntary motion, and kills sooner than a lethargy.

In the cure of these diseases, three intentions should chiefly be regarded: 1. To rouse the patient from sleep. 2. To remove the difficulty of circulation, and the stagnation or extravasation of the blood or serum in the head. 3. To restore the strength of the membranes and vessels of the brain.

Those remedies are efficacious in the first case, which act on the nervous parts, by inducing a tremulous and oscillatory motion through the whole nervous system: such as powerful acids, mixed with tincture of castor; volatile salts; fetid things, as galbanum, burnt partridges feathers; cold water thrown on the head; cataplasms made with vinegar, rue, bay-leaves, tops of savory, mustard-seed, castor, and camphor, applied to the head, forehead, and temples.

The ferous colluvies is derived from the head by sternutatories; the best is ten grains of salt of white vitriol dissolved in half an ounce of marjoram water, and drawn up the nose; blisters on the feet and neck; cupping-glasses; either with or without scarification; strong frictions on the lower parts; stimulating clysters, with the addition of *sal. gem.* common salt, or the root of squills.

To remove the stagnation, and promote the circulation, if the vessels are turgid with blood, venesection is necessary; then gentle laxatives, and nervous medicines with diaphoretics. A powder made of salt of hartshorn, salt of amber, cinnabar of antimony, and bezoar mineral, has very great and salutary effects.

A carus, especially the first species of it, requires plentiful bleeding; and the patient must be roused by clysters, rendered stimulating with the powder of squills; by blisters; by putting distilled vinegar in the nostrils; and

and by appeasing the orgasm of the fluids with cooling fixed diaphoretics and acids. The second species requires but little or no assistance; and the third is incurable, at least if blisters fail.

A coma fomolentum is divided into ferous and sanguine. The first requires the natural ferous evacuations to be restored or promoted. Gouty fits are to be invited by frictions of the feet, blisters, relaxing applications, and warm baths. Sternutatories are of great use, as they discharge the serum through the nose, and stimulate the nerves. When a viscid phlegm offends the stomach, vomits are useful, with half a scruple or a scruple of powder of squills, or ij gr of emetic tartar, with a laxative potion.

In a sanguine coma fomolentum, when the blood circulates slowly, or stagnates in the head, as in the hypochondriac or scorbutic, all hot spirituous remedies are as bad as poison: But bleeding, clysters, gentle laxatives, cooling and nervous powders, are useful.

A red face, eyes turgid with blood, indicate bleeding. Warm baths are bad in all sleepy disorders; likewise saffron, poppies, and opiates of all kinds.

Of the CATAPLEPSY.

The catalepsis is also called catochus, and catoché; and whoever is affected with it is in an instant rendered as immovable as a statue, without sense, and without motion; and continues in the same posture they were in at the moment they were seized.

The proximate cause of this disease is the immobility of the common sensory from the time of the first attack; therefore there is an absolute rest of the blood in the brain, of the glands of the brain, and of all its emissaries; whereby all the functions of the brain are injured, as well as those that depend thereon: The muscles only remain tense as in the beginning; the respiration and pulse indeed continue, but they are very faint.

But Hoffman asserts, that the pulse is natural, and the breathing free and easy; that the limbs are moveable, but remain in the same situation in which you place them. They neither hear nor see, though their eyes are open; nor feel, though they are pricked ever so much; yet, if you thrust any thing into their mouths, they will swallow it: But their bodies are so bound, that you cannot thrust the finest pipe into the anus. The colour of the face continues florid. At last they fetch deep sighs, and come to themselves, and tell wonderful things of what they have seen and heard during the paroxysm; some declare they have enjoyed exquisite pleasures, or seen tragical fights, or have had divine visions. and the conversation of angels.

This disease is generally preceded by obnate intermitting fevers, especially quartans; by a dry, melancholy, lean temperance of body; by a retention of the menses, and hæmorrhoids; by great and sudden frights; by a profound, constant, fixed meditation on one object, or by strong fevers in persons of a sanguine constitution.

The method of cure is various, according to the different causes. The patient should be excited with things that greatly strike the senses; such as light, noise, stimulating things, volatile salts, pain, frictions, continual agitations; by causing an hæmorrhage of the nose; by promoting the hæmorrhoidal or menstrual flux; by sternuta-

tories and emetics; by blisters; by issues; by setons; by a moistening diet.

Of the VERTIGO.

A vertigo, giddiness, or swimming in the head, is a disorder in which all visible objects seem to turn round, attended with staggering, or danger of falling.

A giddiness, when it is not an original disorder in the head, is caused by a long turning round of the body; by looking from a high place; in some, by passing over a broad river, by riding in a coach, by sailing in a ship or boat, and by drunkenness.

A higher degree of a vertigo is a scotomia, when the patient is seized with a sudden dimness or temporary deprivation of sight. The highest degree of all is, when he falls down in the fit: This borders nearly on the epilepsy.

But it may be doubted whether a scotomia is always a symptom of a vertigo, properly so called; because it often follows great hæmorrhages, long fasting, and very hard labour.

A vertigo will sometimes arise by consent, from disorders of the stomach; and, as Etmüller observes, often merely from fasting, and then a morsel or two of bread will drive it away.

An inveterate vertigo, beginning without any manifest external cause, foretells in young men an epilepsy, in old men an apoplexy.

The vertigo often arises from a congestion of blood in the head, when the patient is plethoric; or where any usual evacuation of blood is suppressed, or from an omission of bleeding when accustomed thereto. It affects some whole heads are debilitated with hard study, or whose stomachs are loaded with vitiated, especially bilious, humours.

In plethoric cases, laxatives, bleeding in the foot, pediluvia, resolving attemperating powders, cinnabar, nitre with an infusion of tea or betony, are proper. If from a suppression of an usual hæmorrhage, it is to be promoted; but, if this cannot be done, bleeding must be substituted.

Outwardly, camphorated spirit of wine alone, or mixed with spirit of hartshorn, applied to the top of the head and temples, will be useful; or Hungary-water, or volatile salts, or spirit of lavender, may be held to the nose. The same things are good when it proceeds from hard study, with moderate diet and frequent exercise. As also a glass or two of wine at meals, and other strengtheners. But because many learned men have been hurt by the external use of volatile and fragrant spirits as well as apopleptic balms, these are to be tried with great caution.

If a vertigo proceeds from crudities in the stomach, they should be prepared or dissolved by neutral salts, such as tartar-vitriolate; and then they should be evacuated by an emetic; but, if any thing forbids, by a purge. Afterwards give stomachics and cephalics. and advise a moderate use of wine at meals, a sparing aromatic diet, and exercise of the body. Pyrmont water is excellent in this case.

Of the HYSTERIC PASSION.

The hysteric passion is a spasmodico-convulsive affection of the nervous system proceeding from the womb, and caused

caused by the retention or corruption of the blood and lymph in its vessels; and more or less infesting the nervous parts of the whole body, by means of the nerves of the os sacrum, the loins, and the whole spinal marrow.

This disease has been very improperly confounded with the hypochondriac passion; for a strangulation of the fauces, an intercepted breathing even to suffocation, a fainting away, a loss of voice, a profound sleep, are the true, proper, and essential signs and symptoms of this uterine disease.

An hysterical fit is generally preceded by a pressing pain in the forehead, temples, or eyes, with an effusion of tears and dimness of sight, a dulness of the mind and senses, and a loathing of all things. When the fit comes on, the patient is exceeding collicive, and yet has a strong stimulus to discharge her urine, which is as clear as water; the breathing is uneasy, difficult, and short; and a languor seizes the whole body. To these succeed a pain in the loins, and a great shivering and shaking; the belly is hard and inflated; afterwards the navel is drawn inwards, and outwardly leaves a great pit; then they feel a fort of a globe arise from the lower part of the belly to the hypochondria and diaphragm. Soon after, the heart begins to flutter and beat, with a hard, unequal, and sometimes intermitting pulse; the extreme parts grow cold; the fauces are straitened, and seem to be bound with a cord; the face is pale, the breathing exceeding difficult, the voice ceases, the pulse is almost imperceptible; and there is such a stricture of the belly, that no flatus can be emitted, nor no clyster given. In some there are convulsions of the head and limbs; others lie in a profound sleep, without sense or motion; others have their face and neck look red and inflamed, with a strong pulse; and others again break out into immoderate laughter, and, regaining their voice, say a great many silly things.

When they begin to come to themselves the pulse, which was before weak, languid, and obscure, becomes brisk, soft, and strong; heat returns to the extreme parts; the face which was pinched in and pale, begins to expand and look ruddy; the wind forces its way upwards; there is a rumbling in the belly; and at length the patients, waking, as it were, out of a profound sleep, have the voice, senses, and motion restored. Yet they complain of a heavy pain in the head; a languor of the body, feet, and thighs; some have continued in a fit so long that they have been laid out for dead, and have been even buried.

The hysterical passion attacks women that are pregnant, in child-bed; widows that are full of blood, after some grievous passion of the mind; or maids, after a sudden suppression of the menstrual flux. It likewise oftentimes comes on so suddenly, violently, and at unawares, that being deprived of all sense and motion, they immediately fall down.

This disease may be caused by whatever promotes a more plentiful and rapid afflux of blood and the genital fluid to the uterine parts, or impedes the eruption of the menses, or occasions their suppression; hence maids and widows are most subject thereto; also women of a sanguine or bilious constitution, who live high, drink generous wines, feed on high seasoned aliment, and are subject to violent passions and commotions of the body and mind. On the other hand, those who live a sedentary life, feed

on coarse, acid, low diet, who have omitted usual bleeding, who are oppressed with sorrows, cares, and disappointments, are liable to this disease; for by these the blood is thickened, the solid parts weakened, and consequently the flowing of the menses rendered more difficult. Likewise sudden terror, and the body being exposed to uncommon cold during the time of the menstrual flux, by giving it a check procure hysterical spasms.

However dreadful and cruel this disease may appear, yet it is not very dangerous in itself, unless ill managed, or the patient be exceeding weak and valetudinary: it is most apt to turn into convulsions and an epilepsy. When it proceeds from abortion, or hard labour, it is very liable to return from any slight irritation of the nervous system. Nor is it very uncommon for the hypochondriac and hysterical disorders to be united, and then the cure is very difficult. This happens to women who lead a sedentary life, indulge extravagant affections of the mind, and are guilty of errors in diet and regimen.

In the cure, it must be carefully observed whether the woman is plethoric, or exhausted of blood and strength. In the former case, the spasms or convulsions are more violent, and copious bleeding is a present help; and many have been brought to themselves who were seemingly dead, if the florid colour of their faces had not shewn the contrary.

In the fit, it will be proper to apply fetid things to the nose; such as *asa fetida*, preparations of castor, partridges feathers burnt, &c. For women in childbed, a girdle made of Russian leather, and bound pretty tight, is excellent. Likewise clysters made with roots and seeds of lo-vage, which are specific: camomile flowers, elder-flow-ers, veronica, the carminative seeds boiled; to which may be added oil of elder, dill, or camomile.

Externally, plasters made of opoponax, bdellium, galbanum, sagapenum, and asa-fetida, may be applied to the navel; or,

Some greatly commend fumigations for the uterus of musk, civet, storax, and benjamin.

Inwardly, the patient may take 30 or 40 drops of tincture of castor in cold water.

Some hysterical disorders observe the lunar phases, and partake of the nature of an epilepsy: They seldom require bleeding, and purging should be used with caution: Emetics are of greater service, especially a little before the fit. In the fit, the best medicines are those which repair the loss of spirits, as Russian castor, gum-ammoniac, salt of amber in pills.

Out of the fit, native cinnamon and wild valerian root are most proper for correcting the juices.

To prevent its degenerating into a chronic disease, particularly the hypochondriac passion, care must be taken to keep the menses regular; which must be done by balsamics, composed of myrrh and amber, with bitter and carminative extracts, especially zedoary and orange peel, made into an elixir, with a moderately spirituous menstruum. This, frequently taken, helps the digestion, and promotes a regular menstrual discharge.

But it is necessary to observe, that in hysterical cases remedies have a different effect on different women. Some cannot bear fetid medicines, which to others are an immediate

mediate relief. Some have fallen into a terrible syncope, and have come to themselves by sprinkling cold water on the face, when more powerful and spirituous things have failed. Others cannot endure hot things inwardly nor outwardly, as baths, fomentations, liniments, and nervous applications. Anodynes and opiates, which procure ease and rest to some, are very injurious to others who are greatly debilitated, and whose nerves are weak. Some have recovered from a violent paroxysm, by a draught of cold water; which, given to others, has increased the disorder.

Peruvian bark given morning and evening, a scruple at a time, is an excellent remedy in hysterical convulsions.

Of the HYPOCHONDRIAC PASSION.

THE hypochondriac passion is a spasmodico-stultulent affection of the stomach and intestines, arising from an inversion or perversion of their peristaltic motion, and by a consent of parts, throwing the whole nervous system into irregular motions, and disturbing the whole animal economy.

This disease is attended with such a train of symptoms, that it is a difficult task to enumerate them all; for there is no function or part of the body, that is not soon or late a sufferer by its tyranny. It begins with tensions and windy inflations of the stomach and intestines, especially under the spurious ribs of the left hypochondrium, in which a pretty hard tumour may sometimes be perceived.

With regard to the stomach, there is a nausea, a loathing of food, an uncertain appetite, sometimes quite decayed, and sometimes strong; the aliments are ill digested, breeding acid and viscid crudities; there is a pressing, heavy pain in the stomach, chiefly after meals; a spasmodic constriction of the gullet, a frequent spitting of limpid phlegm, an impediment of swallowing, a violent heart burn, a heat at the stomach, very acid belchings, a reaching to vomit, vomiting, bringing up such acid stuff, that the teeth are not only set on edge thereby, but the very linen or sheets are sometimes corroded.

In the volume of the intestines, especially the small ones about the navel, there are felt heavy excruciating pains, wringings, grippings, with a rumbling murmuring noise; in the gross intestines the pains are more acute. Sometimes there is a looseness, sometimes a most obstinate costiveness, with a retention of the wind; which, when it breaks out either upwards or downwards, is attended with an alleviation of the symptoms, but they soon rage again with as great violence as ever. When there is a frequent urging to go to stool, tubercles generally arise, and the blind piles beset the anus; nay, sometimes a symptomatic flux of blood will burst out. Making water in some is difficult and painful; the urine is thin, limpid, and pale; sometimes it has a copious sediment mixt with sabulous concretions, and often resembles a fit of the gravel.

In the breast there is a great straitness, constriction, excessive difficulty of breathing, sometimes with a sense of fulness, a fluttering and palpitation of the heart.

As the disease increases, the head is molested with an head-ach, mercurianum, various fixed spastic pains, and what is commonly called the *clavus hystericus*. A noise

in the ears, with difficulty of hearing; the eyes are clouded with a scotomia; some have double vision, or a pain and dryness of the eyes. In the tongue there is a most troublesome burning pain fixed to a certain space, with a plentiful excretion of spittle, as if the patient was in a salivation.

At length the animal functions are impaired; the mind is disturbed on the most trivial occasions, and is hurried into the most perverse commotions, inquietudes, anxieties, terror, sadness, anger, fear, or diffidence. The patient is prone to entertain wild imaginations and extravagant fancies; the memory grows weak, and the reason fails.

Persons are most liable to this disease from twenty to fifty, and whose solids are soft, lax, and flabby, and their blood-vessels small; as also who are naturally languid, or have been weakened by tedious maladies. Likewise those who lead sedentary lives, and study too hard; inasmuch that this is the peculiar disease of the learned.

The remote causes of these disorders are the suppression of the hæmorrhoids and menses, and other periodical fluxes of blood; an hereditary disposition thereto; a cold and moist constitution of the air; gross, impure, stultulent diet; a sedentary, studious life; sadness, cares, troubles, intense thinking on a single object; tedious diseases not rightly treated; hard labour in child-bearing.

As to the prognostics, if the disease be recent and left to itself, it is rather troublesome than dangerous; but if it be inveterate, and not skilfully treated, or a bad regimen is followed, it is attended with more grievous symptoms, producing obstructions and ichirri of the viscera, a cachexy a dropsy, an hætic, a convulsive asthma, an incurable melancholy or madness, a fatal polypus, &c. But if it is caused by a suppression of the menses, or bleeding piles, the restoring the flux is the cure of the disease.

As continual fear and diffidence are symptoms of this disease, the patients are always foreboding terrible things, and live in constant dread of death; which render them fickle, impatient, and prone to run from one physician to another. Therefore, when a cure is attempted, they must be admonished to be constant and patient; and then the following indications may be pursued: 1. To correct and evacuate the acid, viscid, bilious slith, and stultulent fordes from the primæ viæ, which yield continual fuel to this disease. 2. The spasms being appeased, to restore the natural order of the peristaltic motion of the intestines, and to recover it from a languid state, that there may be a due concoction of the aliment, and a laudable chyle and other fluids generated. 3. To disperse the stagnated juices; to render the circulation of the blood equable through the abdomen and the rest of the body; and to free the fluids from all acrimony, after facilitating the excretions by urine and through the skin. 4. And lastly, to corroborate the whole nervous system.

To answer the first intention, nothing is better in the fit than clysters made with emollient herbs, water-gruel strained, camomile-flowers, the tops of yarrow, the oils of sweet-almonds, dill, camomile, linseed, &c. adding a carminative species made of caraway, dill, but more especially cummin seeds. These should be repeated, if the spasms render them ineffectual. If the fæces are hardened

ed, it will be proper to give oil of sweet almonds and water gruel inwardly. Nor must gentle laxatives of manna, rhubarb, and cream of tartar, be neglected, with a few drops of oil of juniper.

If there is a great deal of acid filth in the stomach, crabs eyes alone will purge.

To correct the forces in the *primæ viæ*, give the absorbent, precipitating, and antispasmodic powers, such as crab's-eyes, mother of pearl, pulvis marchionis, purified nitre, prepared amber, cinnabar, tartar-violatole, with a little callosr. It will also be proper to take a decoction of any of the following things in the morning in bed, to promote a diaphoresis, *viz.* balm veronica, betony, agrimony, scordium, carduus benedictus, tops of yarrow, daily flowers, camomile flowers, fennel seed, &c.

To restore the digestive power of the stomach, give effence of orange-peel, tincture of tartar, dulcified spirit of nitre, &c.

The paroxysms are relieved by tepid pediluvia, made of wheat, bran, water, and camomile flowers. The feet must be put pretty deep therein.

Out of the fit, to discuss the stagnation of the blood, bleeding in the foot will be necessary, especially at the equinoxes, and at other times as occasion shall require; but this should be after laxatives and pediluvia. If there is a disposition to an hæmorrhoidal flux, leeches should be applied every month to the anus; and the patient should also take balsamic pills, with antispasmodic nitrous powders.

To strengthen the nervous system, nothing is better than chalybeates; for they, by a gentle attrition, restore the nerves to their former strength. Outwardly a saponeaceous plaster, with camphor, may be laid to the hypochondria with no small advantage.

Nothing is more friendly, nor gives greater energy to the blood and spirits, than riding on horseback almost every day, and for a considerable time together. Nor does riding in a coach want its share of salutary effects.

OF MELANCHOLY AND MADNESS.

MELANCHOLY and madness may be very properly considered as diseases nearly allied; for we find they have both the same origin; that is, an excessive congestion of blood in the brain: they only differ in degree, and with regard to the time of invasion. Melancholy may be looked upon as the primary disease, of which madness is only the augmentation.

When persons begin to be melancholy, they are sad, dejected, and dull, without any apparent cause; they tremble for fear, are destitute of courage, subject to watching, and fond of solitude; they are fretful, sickle, captious, and inquisitive; sometimes niggardly to an excess, and sometimes foolishly profuse and prodigal. They are generally colicive; and when they discharge their excrements, they are often dry, round, and covered with a black, bilious humour. Their urine is little, acid, and bilious; they are troubled with flatulencies, putrid and ferid crustations. Sometimes they vomit an acrid humour with bile. Their countenances become pale and wan; they are lazy and weak, and yet devour their victuals with greediness.

Those who are actually mad, are in an excessive rage when provoked to anger. Some wander about; some make a hideous noise; others shun the sight of mankind; others, if permitted, would tear themselves to pieces. Some, in the highest degree of the disorder, see red images before their eyes, and fancy themselves struck with lightning. They are so falacious, that they have no sense of shame in their venereal attempts. When the disease declines, they become stupid, sedate, and mournful, and sensibly affected with their unhappy situation.

The antecedent signs are, a redness and suffusion of the eyes with blood; a tremulous and inconstant vibration of the eye lids; a change of disposition and behaviour; supercilious looks, a haughty carriage, disdainful expressions, a grinding of the teeth, unaccountable malice to particular persons; also little sleep, a violent head-ach, quickness of hearing, a ringing of the ears; to these may be added incredible strength, insensibility of cold, and, in women, an accumulation of blood in the breasts, in the increase of this disorder.

These things being duly considered, together with the state of the brain in persons who died of this disease, we may conclude, that melancholy is a strong and lively working of the fancy, with a fixed attention of the mind to a particular object, which it continually dwells upon; together with a delirium, a long continual dejection, dread and sadness without any manifest cause, arising from a difficult circulation of blood through the vessels of the brain, where it is too copiously congested and becomes stagnant. Madness is a violent rage, attended with rashness and preternatural strength, caused by an impetuous motion of a thick melancholic blood through the vessels of the brain. It differs from a phrenzy, which is a delirium accompanied with a fever, and arises from an inflammatory stagnation of the blood in the brain: for we learn from experience, that all the shining faculties of the mind are changed or depraved, diminished or totally destroyed, when the blood and humours, receding from their natural temperament and due quantity, are not conveyed to the brain in a moderate and equable manner, but on the contrary with an impeded, slow, and languid motion, or with too brisk and violent an impetus.

Both these disorders suppose a weakness of the brain, which may proceed from violent disorders of the mind, especially long continued grief, sadness, dread, uneasiness and terror; as also close study and intense application of mind, as well as long protracted lucubrations. It may also arise from violent love in either sex, especially if attended with despair; from profuse evacuations of the semen; from an hereditary disposition; from narcotic and stupefactive medicines; from previous diseases, especially acute fevers. Violent anger will change melancholy into madness; and excessive cold, especially of the lower parts, will force the blood to the lungs, heart, and brain; whence oppressive anxieties, sighs, and shortness of breathing, tremors and palpitations of the heart; thus vertiges and a sensation of weight in the head, fierceness of the eyes, long watchings, various workings of the fancy intensely fixed upon a single object, are produced by these means. To these may be added a suppression of usual hæmorrhages, and omitting customary bleeding;

bleeding: hence melancholy is a symptom very frequently attending hysteric and hypochondriac disorders.

The causes which contribute to the generation of a thick blood, are idleness and inactivity, which weaken the body, impair the functions, diminish the salutary excretions, and render the humours thick, viscid, and stagnant: All which are heightened by solitude, which is apt to give rise to various fantastic and gloomy ideas in the patient's mind.

Likewise acid humours in the stomach will increase the appetite, and tempt them to feed on coarse, gross, flatulent aliments, without drinking enough to dilute them sufficiently, whence a matter proper to nourish these diseases will proceed. It is evident from observation, that the blood of maniac patients is black, and hotter than in the natural state: besides, the serum separates more slowly and in less quantity than in healthy persons. The excrements are hard, of a dark-red or greyish colour, and the urine is light and thin.

Diseases of the mind have something in them so different from other disorders, that they sometimes remit for a long time, but return at certain periods, especially about the solstices, the times at which they first appeared. It may likewise be observed, that the raving fits of mad people, which keep the lunar period, are generally accompanied with epileptic symptoms.

This disease, when it is primary or idiopathic, is worse than the symptomatic that accompanies the hysteric or hypochondriac passion, which is easily cured; as is that also which succeeds intermitting fevers, a suppression of the menses, the lochia, the hæmorrhoids, or from narcotics. When the paroxysms are slight in the idiopathic kind, the cure is not very difficult: but if it is inveterate, and has but short remissions, it is almost incurable; which is often owing to this, that they reject physicians and their medicines as poison. It is a bad sign if, after a profound sleep, the patient still continues delirious, and is insensible of cold, or is unaffected with strong drastic medicines. If after want of sleep and long abstinence the patient is exceeding weak, or becomes epileptic, convulsive, or lethargic, death is not far off. Mad people are seldom subject to epidemic or other disorders, and some have lived seventy years and upwards in this unhappy state.

Sometimes this disease terminates by critical excretions of blood from the nose, uterus, or anus. Sometimes diarrhœas and dysenteries will terminate these disorders. Pustules, the itch, and ulcers, have also done the same.

In the cure, bleeding is the most efficacious of all remedies; and where there is a redundancy of thick, grumous blood, a vein is first to be opened in the foot, and a few days after in the arm; then in the jugular vein, or in the nostrils with a straw; and, last of all, the frontal vein with a blunt lancet, for fear of hurting the pericranium a ligature having been first made round the neck to render the veins tumid.

Tepid baths are also convenient, to drive the blood from the head to the inferior parts; and before the patient enters the bath he should have cold water poured on his head, or it should be covered with a cloth dipt therein; for cold water pumped or poured on the head con-

stringes and corroborates the vessels of the brain weakened with stagnant blood, and promotes the more easy dissolution of the humours congealed therein.

Purgatives are likewise useful; but the lenient are preferable to the drastic: Thus manna, cassia, rhubarb, cream of tartar, tartar-vitriolate, are most convenient when the disease arises from the hypochondriac passion, and a stagnation of the blood in the intestines, and the ramifications of the *vena portæ*; especially when they are taken in decoctions and infusions, not all at once, but at repeated intervals, so as to operate in an alterative manner.

Some kinds of mineral waters are also highly efficacious in melancholy and madness; for since madness generally derives its origin from the melancholy, and melancholy from the hypochondriac passion, and the hypochondriac passion from impure and peccant fluids slowly circulating through the intestines and viscera of the abdomen, the circulation of the blood ought to be rendered free and easy. It is no wonder therefore that mineral waters have been held in high esteem for the cure of these disorders, for these being impregnated with a highly pure alkaline and neutral mineral salt, if they are drank in a due quantity, they not only change the peccant humours, but incise such as are thick, render the glutinous fluid, and open the obstructions of the vessels; they also relax the tense fibres of the solids, and corroborate the weak and tender, as well as, by stimulating the excretories, they restore all the salutary excretions. The waters of Selters mixed with asses or goats milk have not their equal in these cases. They should be drank in the spring and fall for five or six weeks. The proportion is one part milk to three of water.

But, after all, there is nothing better to remove the cause of these disorders than depurated nitre, but especially in that species of madness which inclines to melancholy; for it corrects the bilious acrimony of the humours, allays the tumultuous motions of the solids, by diminishing the preternatural heat. Sennertus and Riverius affirm, that nitre, given with a little camphor, is a specific in madness.

Particular medicines among vegetables are, balm, betony, vervain, brook-lime, sage, wormwood, flowers of St John's wort, of the lime-tree and camphor: from animals, asses blood dried; among minerals, steel, cinabar, fugar of lead, and the calx and tincture of silver.

Camphor is much praised by the moderns, particularly by Etmuller.

And Dr Friewald affirms, that with a few doses of camphor, of xvj grain each, in pills, he has cured several mad patients, even in inveterate cases.

Stahl recommends a powder of the following cephalic and nervine herbs; vervain, sage, betony, with plain-tain and white maidenhair.

As to diet, the patient should carefully abstain from salt and smok-dried flesh, whether beef or pork; from shell fish; from fish of a heavy and noxious quality; from aliments prepared with onions and garlick, all which generate a thick blood. In general, he should eat no more than is necessary to support nature. Small-beer or pure cold water are the best drink. Sweet and strong wines are highly prejudicial; as is also excessive smoking tobacco,

tobacco; for it not only penetrates thick blood, but throws the fluids into preternatural commotions. Change of air and travelling may be beneficial.

Though in deliriums bleeding is highly useful, yet it agrees best with those that are plethoric, bilious, and in the vigour of youth: these likewise will bear frequent purges of corrected hellebore; but then the strength must be repaired by cordial, corroborating, and anodyne sedatives. When the patient is exhausted, bleeding is hurtful, and restoratives good.

As a high degree of the itch has terminated these diseases, it will be proper to make issues in the back, or to procure ulcers with a potential cautery near the spine of the back.

Sedative medicines are good; but not opiates and narcotics, for these induce stupidity and folly. Those that are good in an epilepsy, will be beneficial here; such as callos, shavings of hartshorn, the roots and seeds of piony, and anti epileptic powders, the valerian root, flowers of the lily of the valley and of the lime tree.

And to the other sort of madnes, which proceeds from being exhausted and weakened by autumnal, violent, and obdurate intermitting fevers, and from their being injudiciously treated with bleedings and purgings, it is only to be cured by restoratives, cordials, and corroboratives, long persisted in.

Of the HYDROPHOBIA.

THIS disease, as it generally proceeds from the bite of a dog, is called *rabies canina*, or the canine madnes; and from its most terrible symptom, the dread of water, *hydrophobia*. It almost always arises from the infection communicated by the bite of a mad animal: yet it has been observed to arise spontaneously in some animals affected with acute diseases.

Almost all kinds of animals may be afflicted with this disorder, and may infect other animals, and even men; as dogs, cats, wolves, foxes, horses, asses, mules, horned cattle, hogs, monkeys, and cocks; but it most frequently attacks the dogs, wolves, and foxes, without any previous contagion.

A hot climate, excessive heats and sudden colds: a long and dry season; feeding upon putrid, stinking, verminous flesh; want of water; worms generated in the kidneys, guts, brain, or nostrils; are the preceding causes of madnes in these animals.

When they are going to run mad; they appear dejected, shun company and hide themselves: they will not bark, but seem to mutter or murmur, and are averse to food and water; they will fly upon strangers, but retain some regard for their master; their ears and tails hang down, and they walk along as if they were sleepy. This is the first degree of the disease; and, though the bite is then bad, it is not at the worst. Afterwards they begin to pant, hang out their tongues, froth at the mouth, and gape. Sometimes they seem dull and half asleep; sometimes they will run, but not directly forward, and soon cease to know their masters. Their eyes are dejected, look watery and dusky, their tongues are of a lead colour, they fall away suddenly, and grow raging mad. A bite at this time is incurable; and the nearer they are to

death, with the more dreadful symptoms it is attended.

There is scarce any poison infectious so many ways as this: for it takes effect through the cloaths, without fetching blood; by the breath of the animal drawn into the lungs; by a touch of the froth, if recent; and by applying it to the lips or tongue, when it has been long dried; or by kissing a dog that is mad; or by handling the wound or instrument which was the death of the animal; or by handling things which have been infected by any of the former means.

Again, there is scarce any poison which produces such terrible effects, and causes such a wonderful change in the person infected. When it begins to work, it is most violent and quick; and yet, as it is said, it will sometimes lie dormant for years together before it exerts itself. This diversity depends on the heat of the season, the degree of the disease of the infected animal, and the temperament of the person bit. For the bilious are soonest affected by it; the phlegmatic and hydropic the least; likewise something may be attributed to the way of living, diet, and medicines.

A healthy man, infected with this contagion, finds the effects of it discover themselves in the following order. There is a pain in the place where he was bit, or received the contagion; and then wandering pains in the other parts, chiefly those that are near it; a lassitude, heaviness, listlessness of the whole body; inquiet troubled sleep, and terrible dreams, with convulsions, and subultus of the tendons; continual inquietude; sighs, sadness, love of solitude: This ends the first degree of the disease. Afterwards all the former symptoms increase, with a prodigious straitness or oppression about the præcordia; a difficult sighing respiration; horror; a shaking and trembling at the sight of any liquid, or bright, pellicid thing; loss of appetite; a possibility of swallowing any thing solid; but, if any liquid is touched with the lips and tongue, it occasions an incredible anxiety, trembling, and terrible convulsions, almost forcing the patient into a rage; then a vomiting of dark, bilious, viscid matter, or porraceous bile; an increased heat, a fever, continual watching; a priapism; a confused series of wild, extravagant thoughts: Here the second degree of the disease may be said to terminate. Now all the symptoms grow worse and worse: the tongue hangs out, and is rough; the mouth is wide open; the voice is hoarse; the thirst great; strange horrors, starting, and wild looks, at the sight of water; a frothing at the mouth; an involuntary inclination to spit at the by-standers, as also to bite them, which the patient cannot resist. He foams at the mouth, and gnashes with his teeth; and would do mischief, if not forcibly with-held. His pulse and breathing fail: there is a cold sweat, and the highest fury: yet during all this time, which is wonderful, the patient continues in his senses, and is afraid of doing any harm. On the fourth day from the first degree of the disease, the patient falls into convulsions, with great difficulty of breathing; and then dies.

The dissection of persons who died of this disease has shewn, that the organs of swallowing have been in some measure inflamed: that various kinds of bilious viscidities are collected in the stomach; that the gall-bladder is full

of a black bile; that the pericardium is dry; that the lungs are incredibly distended with blood; that the heart is full of an almost dry blood; that the arteries are full, and the veins almost empty; that the blood is very fluid, and will hardly coagulate when exposed to the air; whereas that which was drawn from a vein three days before, coagulated as usual; that all the muscles, viscera, brain, cerebellum, and spinal marrow, are more dry than common.

The prevention and cure of this disease, except in a few instances, are very doubtful and uncertain: which may be attributed to the boasting pretences of some to specifics, and the neglect of a due method of cure, founded on the history of the disorder.

So far therefore as may be conjectured from the preceding history of the disorder, and from comparing it with other diseases, as also from the few instances which have been attended with a happy event, it seems chiefly to consist in an affection of the nerves, which most nearly resembles convulsions, which occupy the viscera and the vessels thereof; whence arises a disorder in the blood and humours, which is not unlike a gangrenous inflammation. The seat of the disease is chiefly about the stomach and the neighbouring parts.

The preventive cure consists in making deep scarifications, as soon as possible after the bite, in the part affected, and those adjacent to it; that they make a considerable discharge of blood, and apply large cupping-glasses thereon; or it may be burnt pretty deep with an actual cautery. Then it should be made to suppurate by some corrosive application proper for that purpose; and during all that time it should be continually fomented with a pickle made with vinegar and salt: this should be continued for six months at least. The garments he had on at the time of the bite should be cautiously laid aside or destroyed. He should likewise with all convenient speed be dipped in a river, or the sea, making him believe that he is going to be drowned. This is to be often repeated; for the effect consists in terrifying the mind, not in the salt-water, as we have learnt from experience. Then he should also be often and strongly purged with rhubarb, agaric, and the juice of elder-bark.

The patient should also be put into a sweat every morning fasting, with a mixture of aromatic vinegar, sea-salt, and hot water. His feet and hands should also be daily fomented in a warm bath; and he should wash his head, mouth, and fauces.

Let him often drink cold water, and throw it up again by vomiting; and let his drink be acidulated. His aliment should be moist, light, and laxative, and often taken in such a quantity as to vomit it up again. He should likewise abstain from things that are to spicy, from wine, from heating things, from violent exercise, and from commotions of the mind.

The cure should be attempted when the disease is in the first degree, and in the beginning of the second, by treating it as highly inflammatory, by letting blood from a large orifice even to a deliquium, by giving clysters soon after with nitrous or moderately salt water.

After this let the patient be blind-folded, and thrown into a pond of cold water; or let cold water be thrown

upon him till the dread of it almost ceases; then let a large quantity be forced down his throat: let this be his treatment daily, and at night let sleep be procured. And this method is better than that pernicious one of giving him the most acrid heating and drying medicines; which exasperate the nervous system, and are in this case as bad as poison, to a patient already almost parched with heat.

Celsus informs us, that it was the practice of old to put the patient bit by a mad dog into a bath, and there to let him sweat as long as his strength will permit, at the same time keeping the wound open, that the virus might be discharged from it; and then to give him plenty of good generous wine. This being done for three days, they judged him out of danger.

This may give some light into the nature of the pulvis antilyssus published by Dr. Mead, and received into the dispensatory of the college, wherein pepper is one of the ingredients:

1. Take four drams of ash-coloured ground liver-wort, and two drams of black pepper, beat into a powder.

This is to be divided into four doses, whereof one to be taken in warm milk in a morning, fasting, for four mornings successively. After this he is to be put into a cold bath, pond, or river, for thirty days together, early in the morning before breakfast.

Another famous specific is the East-india medicine; which is doubtless an egregious antipsygmotic, and is as follows:

2. Take native and factitious cinnabar, of each 24 grains, and 16 grains of musk. Make them into a powder.

This is to be taken in a tea-cup full of arrac or brandy, and is said to secure the patient for thirty days, at the expiration of which it is to be repeated; but, if he has any symptoms of the disease, it must be repeated in three hours, which is said to be sufficient for a cure.

Dr. Wall of Worcester has found two doses of musk, of xv grains each, to produce very happy effects on two persons labouring under a subfultus tendinum, with extreme anxiety, and want of sleep, from the bite of a mad dog; for it perfectly relieved them from their complaints. We have a singular case of a woman actually seized with an hydrophobia, given by Dr. Nugent; who was cured. He ordered this powder to be taken in honey every three hours, after the head lost 15 ounces of blood, and a pill of 2 grains of pure opium along with the powder, till rest was procured.

Of Poisons.

THERE are three essential marks of poisons which distinguish them from other things that are noxious to human bodies. The first is, that they consist of most subtle parts, and consequently are pernicious in a small quantity. The second, that they pervert, in a short time, the regular motions of the solids and fluids throughout the body, and induce the most grievous symptoms, even death itself. And the third, that they exercise their cruelty on the most subtle fluid, and the most nervous parts.

All the three kingdoms have poisons peculiar to themselves; but the animal kingdom affords the most subtle, which are communicated by the bite of mad or venomous

ous beasts when they are angered. The mineral kingdom produces arsenicals and mercurials; and the vegetable, herbs and plants, of a most acrid, noxious and deleterious quality, such as the most violent cathartics and narcotics.

Every foot of poison seems to have an effect peculiar to itself: thus mercury attacks the fauces and their glands, producing ulcerations therein; arsenic occasions the most cruel torments, convulsions, and mortification of the coats of the intestines; the seeds of datura, a kind of stramonium, induce madness or absolute stupidity; hyosciamus causes a stupor, and so troubles the imagination, that the person affected believes he sees demons and spectres. Opium brings on sleepiness, and a torpor on the mind. Sharp, drastic purges inflame the intestines. The bite of a mad dog occasions the dread of water. The sting of a scorpion produces a sudden and exceeding cold sweat. Litharge, unwarily taken, causes a convulsive colic, with an obstinate constiveness. The berries of deadly nightshade produce madness, rage, or folly; as do also the roots of cicuta terrestris.

The bites of mad animals have been already treated of; and, as for others, it appears from experience, that the bites or stings of other animals, such as spiders, scorpions, and vipers, are most pernicious in hot countries; and neither the insects, nor any other animals, are poisonous of themselves. but their stings or bites, when they are mad, or provoked to anger.

The venom of animals, whether in a rage or madness, communicates an infection by the saliva, milk, and lymph.

The symptoms which follow the bite of a viper, are a sharp, pricking pain in the wounded part; a tumour, which is first red, and afterwards livid, sensibly extending itself to the neighbouring parts; the skin itrets, and breaks out into little bladders: some time after, a remarkable faintness supervenes, with a quick, weak, and sometimes an intermitting pulse, a palpitation of the heart, a stupefaction of the senses, an anxiety of the præcordia, a great sickness of the stomach with bilious vomiting, a dulness of sight, sometimes pains about the navel or the region of the liver, difficult breathing, hiccups, tremblings, convulsions, cold sweats, coldness of the extremities; after which, death closes the scene, unless prevented by timely remedies. If the patient survives, a tumour with inflammation continues for some time. Sometimes a sanies flows from the wound, and pustules appear, like the herpes exedens; the skin becomes yellow, as if the patient had the jaundice.

Hoffman observes, that externally in all venomous bites it will be proper to apply such things as relax and mollify the strictures of the parts, that open the pores, and so procure an exit for the virulent matter.

Boyle observes, that a hot iron held over the wounded part, immediately after the bite, so checks and weakens the venom, that the patient will have nothing to complain of but a pain in the part of short continuance.

But, above all, Mead, from many experiments, recommends the fat of vipers, which, being rubbed into the wounded part, renders all others useless; and, if that is not at hand, it appears from some late trials, that common salad-oil, rubbed warm into the part, will do well.

The bite of a RATTLE SNAKE, hitherto looked upon as a most terrible accident, may now be cured in a simple, easy manner. It is the invention of a negro; for the discovery of which, he had his freedom purchased, and an hundred pounds per annum settled upon him during his life by the general assembly of Carolina.

Take of the roots of plantane and horehound (in the summer the roots and branches together) a sufficient quantity; bruise them in a mortar, and squeeze out the juice, of which give as soon as possible one large spoonful; if the patient be swelled, you must force it down his throat. This generally will cure; but, if he finds no relief in an hour after, you may give another spoonful, which never fails.

If the roots are dried, they must be moistened with a little water. To the wound may be applied a leaf of good tobacco moistened with rum.

The mineral kingdom furnishes very few real poisons: the only natural one is cobalt; the facitious are arsenic, corrosive sublimate, and glass of antimony.

Cobalt is a kind of a marcalite, which is found in great plenty in the mines of Mînsia; and is well known for its poisonous quality, so fatal to insects, brutes, and men. In making the blue glass, or enamel, called finalt, from this mineral, a sort of white flowers arises, which, being melted in a stronger fire, is called white arsenic. If this be melted again with an eleventh part of sulphur, it becomes yellow arsenic, and, with a sixth part of sulphur, red. Of these, the white is the most deadly poison.

As for the true mineral poisons, they were entirely unknown to the ancients; for they reckoned quicksilver, crude antimony, all kinds of vitriol as well as cerus, and the lapis lazuli, in that class; but orpiment, which they called arsenick, as Celsus testifies, and looked upon as a poison, is void of all virulence and deleterious qualities; and sandarach they termed red arsenic, which is made of melted orpiment, but is no more noxious than the former. Indeed, it must be owned, that the above catalogue are not altogether friendly to human nature, or may be ended with a corroding quality; but they want the true characteristic of poisons.

Quicksilver, dissolved in acid mineral spirits, is likewise a poison, though of itself it is entirely innocent. This has chiefly appeared from errors in practice, when the mercury has not been rightly prepared and corrected.

Likewise glass of antimony reduced into powder, and exhibited, causes enormous vomiting, with most cruel gripings, which often end in death.

Arsenic, taken inwardly, creates a pricking, vellicating, irritating, burning sensation, with a heat and most violent pain in the stomach, a racking torture in the bowels, vomiting, unquenchable thirst, a roughness and dryness of the tongue, fauces and gullet, with hiccups; then follow most cruel anxieties, palpitation of the heart; fainting, coldness of the extremities; sometimes black vomits, and stools with a fetid cadaverous smell; a gangrene and mortification of the stomach and intestines, which usher in death.

Milk is very useful against all corrosive poisons, by its soft, oleous texture, blunting their acrimony; and is a good vehicle to bring them up by vomit.

In all cases where a person is suspected to have been poisoned by swallowing any substance of a corrosive nature, oil with milk for a vehicle yields the most certain relief; and even when acid mineral spirits are taken by mistake, they will blunt or sheathe the acrimony sooner than fixed salts and testaceous powder will change their nature: besides, salad-oil is generally at hand in all places as well as milk; and the sooner it is given, the less is the danger.

The most dangerous vegetable poisons, are wolf's-bane, the deadly night-shade, henbane, and datura; to which may be added the roots of *oenanthe cicutæ facie*, or henlock-dropwort, *cicutæ vulgaris* or common hemlock.

Hoffman affirms, that milk in a large quantity is an universal remedy against all poisons that kill by inflammation, and if taken in time will prevent the direful consequences. Allen thinks a vomit with warm water and oil, taken in large draughts and often repeated, will be of great service; as also warm water with fresh butter, milk and oil, or milk and butter. If the above things will not provoke the patient to vomit, oxymel of squills, salt of vitriol, or a decoction of tobacco, may be used, as having a more immediate effect. It is hardly safe to give even the most gentle cathartic.

The stomach being thus emptied of all, or as much as possible, recourse must be had to generous wine and alexipharmics, such as venice-treacle, confectio alkermes, the bezoardic powder, &c. When there is a suspicion that the coats of the stomach or intestines are corroded or ulcerated, it will not be proper for the patient to use spices or vinegar, nor to indulge in too much wine, but to take a decoction of barley with raisins, or a decoction of china-root, saffraas, &c.

The same method is most likely to answer when any other deleterious herb or root has been eaten by mistake, though the particular species should not be known; and Hoffman affirms, that when the patient has been stupified by the narcotics, the best remedies are vomits mixed with oil, to facilitate the operation.

Of a GUTTA SERENA.

A *GUTTA serena*, or amaurosis, is an abolition of the sight, when no fault appears in the eyes, except in the pupil which is larger than usual and more black, nor will it contract, though any luminous object is placed directly before it, but continues quite immovable. It may be distinguished from the disorder of the eyes proceeding from the vertigo; for the objects seem to turn round: From a cataract; for then an opacity of the crystalline humour is perceivable, and the pupil will contract in a glaring light.

When this disease comes on suddenly, it generally proceeds from external causes, as blows, falls, and the like. When it comes on by degrees in old persons, it arises from a hemiplexy or palsy; as also in other weak and languid constitutions. Sometimes its concomitants are pains in the head, the vertigo, sleepiness, noise in the ears, and sometimes it comes on without any preceding symptoms.

From dissections it has appeared, that the optic nerves have been in fault; that is, they are wasted away or much less than common; as also compressed by extravasated fluids, or hard tumours about their origin.

The indications of cure are, to discuss the stagnating humours, which compress the nerves, and then to strengthen the affected parts.

Heister affirms, it is to be cured by aromatics, carminatives, and attenuants; chiefly eye-bright, veronica, hyssop, rosemary-flowers, sage, fennel, and aniseeds, valerian root, saffraas, cinnamon, wood-lice, either in infusion or powder: the juice of wood-lice newly expressed, and taken for some weeks, increasing the dose, is of excellent use; as likewise mercurials, taken in very small doses, and a long while together.

If it arises from a suppression of usual hæmorrhages, they are to be restored; but, if this cannot be done, artificial bleeding is to be substituted.

Externally, issues are held to be good, clysters and setons, especially in the phlegmatic. The eyes may be washed with fennel, valerian, eye-bright, or rose-water, spirit of wine, Hungary water, and sal-volatile oleosum diluted, or an infusion of fennel-roots in wine, with bags of strengthening herbs and fennel-seeds often put thereon. Sneezing powders may likewise be proper, especially florentine orris, or horse chestnuts; likewise spirits of hartshorn, or sal-volatile oleosum, may be applied to the nose.

In all disorders of the eyes, but particularly in this, the body must always be kept open, that the humours may be invited downwards, with laxative pills mixed with calomel. Likewise strong clysters are of very great use.

Of a SUFFUSION, or CATARACT.

A *SUFFUSION*, or cataract, is an obstruction of the pupil, by the interposition of some opaque substance, which diminishes or extinguishes the sight: Some are thicker than others; some are white, black, citron-coloured, or brownish. It is always contained between the uvea and sclerotica, where it sometimes swims and fluctuates like a bit of lawn in the aqueous humour, and sometimes it adheres close to the coats. It is generally an opacity of the crystalline humour.

The medicines above mentioned, in an incipient or recent cataract, from thick or viscid humours, may do good, especially if they arise in the crystalline humour, as Heister affirms, because they attenuate, resolve, and render the humours fluxile, and increase the spirits. A grain or two of mercurius dulcis, given with twice the quantity of prepared oyster-shells for thirty days together, has destroyed the rudiments of a cataract. But, if these have no effect, and the cataract grows inveterate, ripe, or perfect, it is to be depressed; for which, see SURGERY.

Of a GLAUCOMA.

A *GLAUCOMA* is a change of the crystalline humour into an azure colour, from its dryness and condensation, as some affirm: but Heister says, it arises from an opacity of the vitreous humour, which becomes of a whitish green colour: for, in a suffusion, an opaque body is placed behind the pupil, or is next to the uveous part.

Sennertus says, this malady is known from a very remarkable whiteness appearing in the eye, and lying deep behind the pupil, and all things are seen as through a smoke or cloud; it is said to be incurable.

Of the AMBLYOPIA, or Obscurity of Sight.

THE amblyopia is an obscurity of sight, and is fourfold: myopia, or short-sightedness; presbyopia, or seeing only at too great a distance; nyctalopia, or seeing only in the night; amaurosis, of which before.

Myopia proceeds from the too great convexity of the cornea, or crystalline humour, or from the eyes being larger than common, as we learn from optics. This is best assisted by concave glasses.

Presbyopia proceeds from the contrary causes, and receives assistance from glasses of a convex form.

Nyctalopia is a twofold malady, in which the complaints are contrary to each other. In the first species, the sight is best in the night, and in obscure places; but in a clear light the sight fails, and they can hardly see any thing at all. In the other sort, which is improperly called a nyctalopia, they see nothing at all, except in a clear and bright light. This infirmity arises from a naturally bad formation of the eye, and is therefore incurable. The presbyopia may likewise be assisted by cephalic and strengthening medicines, by watery and vinous infusions, and comforting eye-waters.

Of a STRABISMUS, or Squinting.

A STRABISMUS, commonly called squinting, is an unequal contraction of the muscles of the eye, either from a spasm, an epilepsy, or a palsy, whereby the axis of the pupil is drawn towards the nose, temples, forehead, or cheeks: so that the person cannot behold an object directly. Infants readily contract this distemper, sometimes for want of care in the nurses, who place the cradles in a wrong position, with regard to the light. Children likewise, while growing up, sometimes fall into this disorder, either from ill customs contracted in playing, or by looking on others who are affected with it.

This disorder is very difficult to cure; therefore the utmost care should be taken to prevent it, and the cradle should be so placed, as not to occasion the child to look a-ry. Ægineta contrived a mask, and so adapted it to the face, that nothing could be seen except through two holes straight forward; and for the same purpose what we call goggles are used.

Of the ALBUGO, or Spot in the Eye.

AN ALBUGO, or leucoma, is a whitish spot of the transparent cornea; the broader and thicker it is, the more it obscures the sight; when it is superficial, it appears the whiter; and, when it is deeply rooted, it tends to blackness, and is scarce curable. That which is in reality a cicatrix, or scar, left after a wound or ulcer in the eye, is very difficult to be dissipated; that which follows an inflammation of the eye often goes away of its own accord.

It may be distinguished from a cicatrix, because this is of a shining white and without pain; whereas the albugo looks like chalk, is attended with a slight fluxion, and some degree of an inflammation with pain. It is generally the forerunner of an ulcer.

The intentions of cure are answered by emollients, resolvents, and discutients, which must be used with great

caution. To take away a cicatrix, the sharpest topics, nay, cathartics, are sometimes to be used, with a very prudent hand: but, first of all, mild things may be tried; and, if they fail, we may proceed to stronger.

Of a SUGILLATION, or Bloodshot Eye.

A SUGILLATION first appears of a reddish colour, and afterwards livid or black. It is caused by a stroke or fall, or violent vomiting, whereby the blood is extravasated in the coats of the eye. If the cornea is affected very much, all objects appear of a reddish colour; for some veins run to the cornea, in the part towards the iris, or the blood may be poured out into it from the neighbouring vessels.

If the disorder is great, there will be occasion for bleeding and purging, for the grumated blood in the sugillation is to be resolved and dissolved, which may be done by discutients, such as juice of fennel, with balsam of Peru, juice ofcelandine, simple honey-water, mixed with other eye-waters.

If from this or any other cause there should happen to be an ulcer of the eye, Demours recommends coarse sugar as a good ingredient for detaching those of the cornea, in which astringents are hurtful; but it must be mixed with collyria. When the aqueous humour of the eye is evacuated at a wound or ulcer of the cornea, he exposes the patient to the light, from time to time, till the cornea is again raised by the aqueous humour; for the light occasions a motion in the iris, which may prevent its adhesion to the cornea.

Of the EPIPHORA, or Lippitude of the Eyes.

AN epiphora is a defluxion of a salt sharp humour upon the eyes, attended with itching, pain, and redness; as also a dimness of sight. It is but light when there is no defect in the bulb of the eye, when the eye-lids swell and look red, when the matter of the fluxion is thick and sometimes glues the eye-lids together in the night, continuing in this state for some time.

Children are often afflicted with this disease, particularly those who have had a scald-head improperly cured; or who have swellings in the glands of the neck or about the ears, and then it cannot be cured until these tumours are dissolved. It sometimes likewise succeeds the small-pox and measles.

The seat of this disease is in the glands of the eye, especially in those called the lachrymal glands.

This disease may be certainly cured in the beginning, by a plentiful drinking the infusion of the leaves of veronica, in the manner of tea, for some time. When it is inveterate, the patient must be very regular in his diet, and must avoid every thing salt, sharp, acid, wine, strong-beer, and drums. His common drink may be a decoction of hartshorn and fennel-seeds, using warm pediluvia at night going to bed.

Externally a grain of vitriol may be mixed with unsalted butter, to which a small portion of sugar of lead may be added and put into the greater corner of the eye. This is a most useful medicine. When the lippitude is of the dry kind, all acid applications must be avoided, and the eyes must be covered with a poultice of white bread.

bread and milk, with a little saffron mixed with it. The success of ferons and issues is uncertain, but a perpetual blister on the nape of the neck is of great service. But it must be continued for a considerable time.

Of the FISTULA LACHRYMALIS.

THE fistula lachrymalis is a disease which attacks the great caruncle in the inward corner of the eye, and stopping up the natural passage of the tears, forces them to run down the cheek: but this is the first degree of the disease. The second is, when pus is mixed with the tears, which proceeds sometimes from an opening in the skin between the nose and the great corner of the eye. The last is, when the pus has not only corroded the neighbouring parts which are soft, but has affected the bone which lies underneath. This sort of fistula sometimes turns cancerous; and Riverius advises not to meddle with it at all.

Whatever may be the cause of this disorder, whether the small-pox or the French disease, it always stops up the nasal conduit, which is opened by an operation. See SURGERY.

Of DEAFNESS.

THE causes of deafness are a cutting off the external ear, or an obstruction of the auditory passage from wax or other things; from a rupture of the membrane of the tympanum, or when it is corroded or ulcerated, or the auditory nerve is obstructed or compressed. External causes are, falls from high places, excessive noise, such as the explosion of cannon; likewise acute disorders near their stage, which are like to terminate by a critical hæmorrhage.

As to the prognostics, those who are born deaf are rarely cured. A real deafness is hard to remedy. A deafness in acute deafness, with crude urine, foretells a delirium; but, when the signs of costion are good, it portends a critical hæmorrhage.

With regard to the cure; if the obstruction be in the external cavity of the ear, it is discernible by the sight. If there is occasion to syringe the ear, a decoction of sage and rosemary-flowers will be proper, with equal parts of water and white-wine; but great caution should be used. Some pump the head with warm bath waters. Some say, the eggs of ants bruised and put into the ear, with the juice of an onion, cure the most inveterate deafness. Others affirm, that a salivation will sometimes perform a cure.

A critical deafness will cease of itself. Etmuller recommends amber and musk.

Hoffman says, deafness sometimes arises from a slackness of the auditory nerves, which often happens from too great a humidity, which, if neglected, will terminate in a perpetual and incurable deafness, and may be dispersed, if taken in time, by proper cephalics and sudorifics. Some for this purpose recommend equal parts of spirit of lavender and hungary water, which should be dropt warm into the ear. Lindæus advises the gall of an eel mixed with spirit of wine; and others, the fumes of sulphur conveyed into the ear, with a pipe or funnel. But regard must be had to the cause, if discoverable.

Of a TINNITUS, or Noise in the Ears.

HOFFMAN observes, that this is caused by the spasms of the coats of the ear, which line the inward parts, such as the labyrinth, cornea, and auditory passage, which is often attended with intolerable anxiety.

The cure is to be performed, says Heister, by temperate diaphoretic powders, and resolving essences, commonly called anticatorrhæals; as of amber, the woods, rosemary; together with diaphoretics and alexipharmacs, taken often in a day, with tea of betony, with rosemary flowers, sage, or lavender and saffras. In the morning, and at noon, the essences are to be taken, and at night the powders.

Outwardly, essence of amber may be applied, either alone, or with a few drops of oil of amber, or one or two drops of camomile put into the ear with cotton, morning and evening; or a grain or two of amber and musk, or castor in cotton, either alone or with Peruvian balsam; or carminative oils, such as anise, fennel, carraways, or calomel; not neglecting pediluvia, and frequent rubbing of the feet and head.

Of a CORYZA, or Catarrh of the Nose.

A CORYZA is too great a moisture of the nose, by a thin sharp serum, which gradually becomes thick, and sometimes coloured.

The cause of this disorder proceeds from the lymphæ and mafs of blood, most commonly in the winter-time, which hurts the nostrils; at first it arises from a thin, sharp humour, which excoiates the parts, which, becoming more thick, almost stops the nostrils and hinders breathing. Sometimes it arises from sternutatories too often taken, and from mineral fumes; this is accompanied with spitting and a cough. Sometimes the effluvia, affecting the nostrils, have the nature of a ferment, and become infectious.

As to the prognostics, it is without danger, unless the lymph is exceeding sharp and ulcerates the nostrils, and so degenerates into an œzema, or sordid ulcer of the nostrils. Hoffman says, this excretion is often salutary, and is exasperated by purges.

With regard to the cure, the irritation is to be stopped in the beginning, by joining laxatives with sudorifics, according to the condition of the patient, the season of the year, and the reigning diseases. To stop the irritation, oil of aniseed is very proper; but if the nostrils are red, painful, and excoiated, it must be mixed with barley-flour well dried. Camphor dissolved in oil of almonds is likewise good externally applied, and the smell of horns when rasped, as well as the vapours of gum anime, received into the mouth and nose. The vapours of amber, frankincense, mastic, and benjamin, are likewise useful. A coarservation of the mucus may be evacuated by distilled oil of marjoram, amber and aniseed, mixed with leaves of marjoram, and made into snuff; or, by a sternutatory of calcined white vitriol, twelve grains of which may be mixed with two ounces of marjoram water, and filtrated. If the nostrils are obstructed, the vapour of vinegar upon hot iron will be profitable. If the head is heavy and dull, the vertex should be anointed with balsam of Peru, which

may

may be made stronger with oil of amber. To preserve the mouth, troches may be held therein, made with mithridate and blibanum.

To preserve the fauces and windpipe, it is common to take raisins steeped in spirit of aniseed.

Of the OZENA.

THE *ozena* is a fordil ulcer affecting the nostrils; wherein the humour is very acrid or corrosive, intolerably fetid, fanious, and often mixed with a bloody mucus.

With regard to the cure, the leaves of tobacco, or tobacco ointment, are very useful: If it gathers to a crust, it may be removed by oil of sweet almonds. Some make use of the fumes of cinnabar, or inject mercurius dulcis; others use precipitate mixed with an emollient ointment, and applied with tents. Some use an injection of oil of sweet almonds, an ounce with a dram of oil of castor to soften the acrimony of the humours. If the pain be great, they add a scruple of camphor and saffron, with half a scruple of opium. To take away the crust, they make a powder of rosemary and lavender flowers, dried lemon-peel, and common snuff.

When the matter is well digested, the running abated, and the pain gone, it may be cicatrised with lotions, and washed with warm milk.

Of WATCHING.

WATCHING is produced by too great a determination of the nervous fluid to the organs of the senses: from its too great influence in the brain, while the lower parts are obstructed with colds or other causes, as in hypochondriac, melancholic, and mad patients, whose lower parts are cold: by any irritating body, in whatsoever part it is placed, which disturbs the senses, and especially the brain: from too great a motion of the humours, while the passages of the brain are open: from disorders, in which the causes above-mentioned are predominant; as fevers, phrensy, melancholy, pains, suppurations, and such-like disorders.

When the cause is known, it must be removed, if possible; and the irritated spirits must be appeased with emulsions, especially of poppy-seed, or with the thebaic tincture, or theriaca and other opiates in general, not neglecting the original diseases. In fevers, a moist softening diet is beneficial; as also preparations of barley, emulsions of poppy-seeds, and almonds, decoction of scorzonera-roots, almond-cream, and winter flummary, used as aliment; likewise tea made of cowslip-flowers, and gentle laxatives. When the patient is restless and wakeful the night before a crisis, no hypnotics should be given.

When there is no other disease, the patient should shun all care, and intense thinking, especially in the evening; he should use exercise, and eat light suppers. If it is caused by pains, they should be appeased by antispasmodics, things which temperate, and diaphoretics: if these will not do, mild opiates must be added. In old persons, all care and solicitude should be banished, the mind should be quiet, and the moderate use of generous wine may be allowed in the evening; likewise medi-

cines of amber and musk will be proper, and confectio alkermes or theriaca with wine. The drinking of hot-water, and principally coffeee, must be forbid after dinner.

Of the INCUBUS, or Night-mare.

WILLIS observes, that the incubus rarely seizes any one, except during sleep, and when the stomach is oppressed with aliment of hard digestion, especially if the patient lies on his back.

Those that are seized with it, seem to have a heaviness on their breasts, and about their præcordia; and, if they want to speak, they cannot: sometimes they see spectres of various forms, and cannot get rid of the load, or move their body, but after a long struggle: at length they awake, and the imaginary weight vanishes; but sometimes they find a tremor of the heart, and many times a quick and violent vibration of the diaphragm.

Heister observes, that those who have troubled dreams, or walk in their sleep, are to be cured in the same manner, as proceeding from the same cause, and should purge, bleed, and use a spare diet.

Etmuller is much of the same opinion, and advises the patient to eat slight suppers, and to lie with their heads raised pretty high. If it be very troublesome, anti-epileptics may be used, as well as medicines prepared of steel. It frequently affects children, because they eat more than they can digest. There are some instances of its being mortal, though it is generally without danger. Dr White has proved that the incubus is owing to wind in the stomach and bowels; and therefore recommends a dram of brandy before going to bed.

Of the SYNCOPÉ, or Fainting.

HEISTER observes, that this disorder may arise from want of strength from profuse bleeding, from sudden and violent terror and dread, or from the sight of any greatly affecting thing. The patient is deprived of sense and motion, either wholly or in part, with paleness of the face, and a very weak or low pulse. They are generally roused by shaking and pulling, or by volatile medicines; which distinguishes it from the apoplexy.

There are two kinds; the one slight, the other grievous. The slight kind is attended with paleness of the face, disturbed vision, ringing of the ears, and sometimes with a vertigo; the strength fails, and the patient is almost deprived of sense, falls or sinks down, till some proper remedy is applied to the nose and mouth. The more grievous sort is, when the patient falls into a delirium, and is deprived of all sense and motion, except breathing, and a very small pulse; but yet he may be roused by spirituous medicines and other means, much more easily than in the apoplexy.

Besides the causes already mentioned, there may be added the hysterick passion, which seems to proceed from spasms; some of this sort are thus affected with the smell of sweet things. Some incur this disorder by deep study, great inanitions, and fasting.

With regard to the prognosticks, it has generally more terror than danger attending it, unless it proceeds from profuse bleeding, or wounds, or a loss of strength by o-

ther diseases, or a most violent terror: The slighter fainting-fits have little danger; and patients are brought to themselves by volatile medicines, taken by the mouth, or applied to the nostrils.

As to the cure, if the slighter sort happens when a vein is opened, or from the sight of blood, wounds, ulcers, or any chirurgical operation, which proceeds from horror and fear, affecting the imagination, it often happens that changing the room, and going into fresh air, will perform a cure. But if any thing hinders this, that they can neither walk nor leave the room, the smell of hungary water alone, or volatile spirits, or wine and strong vinegar, or sprinkling the face with cold water, or a draught of generous wine, will bring them to themselves.

In more grievous fainting fits, where gentle cordials are of little use, the stronger sort must be applied, such as spirit of sal ammoniac to the nostrils, temples and pulses, with strong frictions; or 40 or 50 drops of volatile spirits may be given inwardly, to which may be added cinnamon water, orange-flower-water, or the like; not forgetting a draught of generous wine, with vellications and frictions of the extremities of the nose, ears, head, hair, &c. till they recover.

When the patient is hysteric, none but fetid things should be applied to the nose, such as castor, asa-fœtida, partridges feathers burnt, or burnt leather, horn, or the like; as also fetid spirits, in a grievous fit; not omitting vellications and frictions of the aforesaid parts.

Of the SPASM of the LOWER JAW.

In the spasm of the lower jaw, when the patient can neither open his mouth, nor eat, as when persons are wounded, and something foreign is lodged therein, or when the nerves are hurt, or when sharp things, such as vitriol, are applied to stop the blood, the cure must be performed according to the diversity of causes, as particularly treated of in surgery. But when this happens spontaneously in infants, they generally die, though the best nervous and antispasmodic medicines have been used both inwardly and outwardly.

Of the CYNIC SPASM, or Convulsion of the Muscles of the Mouth.

A CYNIC spasm, if it proceeds from vegetable poisons, as it generally does, they are to be expelled immediately from the body by a vomit, and then giving generous wine, warm with ginger or pepper. If it happens from other causes, it must be treated with antispasmodics and nervous medicines, both inwardly and outwardly; and chiefly with plaster of betony and bay-berries, prepared with oil of amber, and applied to the temples, and behind the ears.

Of the PALPITATION of the HEART.

THE heart often palpitates so much as to be heard at a distance by the bystanders, which they suppose to be an affection of the thorax. This may sometimes happen, from a violent motion of the body, chiefly when ascending high places, and principally in those who are plethoric and hypochondriac. Sometimes it is caused by fear or dread, when the blood is forced too violently to the heart. When it proceeds from violent motion or terror, and re-

turns often, it causes a kind of polypus, as is evident from the dissection of those bodies who have died of this disease. Hence, almost a continual palpitation arises. Sometimes it proceeds from a bad conformation of the heart and the neighbouring vessels, such as an aneurism of the aorta, when it becomes bony.

Others affirm, it sometimes may be caused by wounds in the ventricles or abscesses in the heart; or from wind, or a disorder of the animal spirits, inducing spasmodic affections.

In the beginning of the cure, if the patient is plethoric, or when usual bleedings have been stopt, it will be proper to bleed, by way of preservation, in the spring and autumn.

Besides this, saline, nitrous, and cinnabarine temperating medicines are to be used, particularly antispasmodics, to appease the motion of the heart, and render the blood more fluid. The aqueous infusions of tea, balm, veronica, primroses, or citrons, are likewise proper, especially with the essence of scordium, cardus benedictus, citron, or orange-peel, with a little dulcified spirit of nitre, taken morning and evening; as also temperate pediluvia, moderate frequent exercise, riding, moderate diet, plenty of thin drink, whey, mineral waters, especially the chalybeate kind, are very useful in this disease.

Of a POLYPUS of the HEART.

A POLYPUS is a mass composed of various pellicles and fibres, generated in the heart and large vessels. They are generally founded in acute as well as chronic diseases; and there are few bodies to be met with, wherein they are not to be found after death. Its principal seat is in the heart, pulmonary artery, and the aorta.

They principally attack the sanguine constitutions, and patients who have smaller vessels, soft fibres, of a sedentary life, who drink little, or are free in the use of acid wines and spirituous liquors, as also those who eat large suppers.

The beginning of a polypus may be known by a compression of the breast, a fixed pain about the heart, and when it increases there is a frequent palpitation of the heart, from a slight cause, and the pulse is strangely unequal and often intermits. When there is a violent motion of the body, or the patient has taken a medicine which disturbs the blood, or the mind is violently affected, a shortness of breath and an incredible anxiety of the heart will arise. Lastly, there are frequent faintings without any evident cause, or from a certain position of the body. If the blood is let fall into hot water, it will congeal like jelly, and cleave into white filaments.

In the cure, an exact regimen and diet must be made use of, with a frequent exercise and motion of the body, and mineral waters, especially those of the chalybeate kind, and abounding with alkalious salt.

Of the HICCU.

A HICCU is a spasmodic affection of the stomach and diaphragm, arising from any thing that irritates and vellicates their nervous coats. When it proceeds from a slight error in diet, it will soon end spontaneously, or by drinking any thing which dilutes the acrid matter. Sometimes

it is of a more grievous kind, and may proceed from a hurt of the stomach, poison, an inflammation of the stomach, intestines, bladder, diaphragm, or the rest of the viscera. Sometimes, immediately before death, it may proceed from gangrenes of the outward parts. In acute fevers, and chiefly the malignant, a hiccup is frequent, and often fatal.

When it happens in old or weak persons, from a plentiful meal, especially from hard and stultent aliment, a draught of generous wine, or a dram of any spirituous liquor, will generally take it away. Likewise stomachic powders mixt with Peruvian bark, and taken in generous wine, are profitable; as also if it proceeds from cold, or drinking cold liquors.

When it proceeds from other causes, especially from acid humours in the stomach, absorbent and alkalious medicines are good. If it proceeds from an acute fever, or an inflammation of the stomach, it is a dangerous disease. However, dulcified spirit of nitre, joined to an alexipharmac, and given often, is proper; a dram or two of diascordium, given in the evening, may perform a cure. If it proceeds from a gangrene or mortification, it is generally incurable; but Peruvian bark, with medicines against internal inflammations, is most likely to succeed. If a poison is the cause, plenty of milk must be taken with oil, as has been already taught.

Of the Soda, or Heart-burn.

This disorder is a heat or troublesome burning about the pit of the stomach, or its left orifice, which sometimes is extended the whole length of the oesophagus, with a preflux or spasmodic constriction, usually attacking the patient by fits. The cause is generally flat aliment, if cold drink be taken soon after. In some it proceeds from acids, in others from aromatics, spirituous liquors, or bilious humours. It frequently torments pregnant women. This disorder is generally slight, and vanishes of its own accord; but in some it is of long duration.

In the cure, the cause must always be attended to: If from acids, absorbents are proper, particularly crabs-eyes and prepared shells, mixed with a fourth or fifth part of powder of nutmeg, given to half a dram. It is common to take chalk alone, or mixed with nutmeg; but care should be taken not to be too free in its use. Oil of tartar *per deliquium*, given from 20 to 30 drops, in tea, coffee, broth, or warm beer, is usually efficacious; as also tincture of tartar and spirit of hartshorn. If it proceeds from bilious humours, 30 or 50 drops of dulcified spirit of nitre in water, tea, or coffee, will take away the pain. When it is caused by fat things, and draughts of cold liquor, a dram of brandy is good. Now and then laxatives should be given, to carry off the humours. In sanguine constitutions, bleeding may be proper.

Of the CARDIALGIA, or Pain of the Stomach.

Of all pains of the stomach, the cardialgia is the most severe. It is a spasmodic pain of the orifice of the stomach, sometimes of the right and sometimes of the left. One kind of this disorder may proceed from a sharp caustic, or poisonous matter; sometimes it arises from a redundant or caustic boil, or from a dysentery. At other

times it may proceed from the blood, when any usual evacuations are suppressed, and the nervous membranes of the stomach are distended thereby. Hence it often happens to women after the fiftieth year; and, in the cure, bleeding or scarifications are proper: on the other hand, if it is deduced from a caustic matter in the stomach, oily appeasing things, asses milk, an infusion of camomile flowers, cream, with absorbents, are proper. It must be distinguished from a painful inflation of the stomach, in which there is a tumour like a bladder under the false ribs, chiefly on the left side, and under the pit of the stomach; but the inflation is generally on the right side, with great difficulty of breathing. This is common in infants before they are weaned; but more so in hypochondriacs, if they are too luxurious.

If it proceeds from the remains of the aliment grown sharp, whence flatulencies arise, it generally gives way to tea or coffee alone, or a decoction of camomile flowers, especially mixed with stomachics; likewise preparations of fennel, anise, orange-peel, and other carminatives are useful; as also a dram of the powder of orange peel, or camomile-flowers, with a few grains of saffron, in an ounce or two of wine.

When the stomach is too much filled with aliment difficult of digestion, or fat things, a gentle emetic will be necessary, especially if there is a nausea or reaching to vomit; after which, a sufficient quantity of warm water must be drank, to wash the stomach: this will be best promoted with a decoction of cardus benedictus, or half a dram of tartar-vitriolate, salt of worm-wood, and the like; after which stomachics must be given.

In a very violent cardialgia, from congestions of blood, vomits are improper, but bleeding necessary, with antispasmodics of tartar-vitriolate, nitre, cinnabar, crabs eyes, and the like, in a proper vehicle; as also spirit of hartshorn mixt with tincture of tartar to 50 or 60 drops. To these may be added emollient and anodyne clysters, and a bladder of hot milk, with camomile flowers, applied to the pit of the stomach.

Of FLATULENCIES and ERUCTATIONS.

THE cause of these disorders is generally a weak stomach, and crude stultent aliment, such as pease, beans, lentils, coleworts, turnips, radishes, hard fat flesh, and the like; which degenerate into wind, creating great anxiety, if not evacuated, and difficulty of breathing. It is a disorder familiar to hypochondriacs. and, the stomach being strongly contracted, the wind breaks out with violence.

Another cause of flatulencies are congestions of blood in the branches of the vena portæ; whence proceed anxieties of the præcordia, difficult breathing, colic pains, and the cardialgia, and, by consent of the stomach with the head, pains in the head, the vertigo, and watchfulness.

If it arises from crudities in the stomach, evacuations are necessary first of all; and then strengtheners, aromatics, bitters, and carminatives, such as have been mentioned in the preceding diseases; with a sparing diet and exercise.

If it proceeds from congestions of the blood in the branches of the vena portæ, which is the case of hypochondriacs, or when usual bleedings are suppressed, a vein must

must be opened; if the body is costive, an emollient clyster or a gentle laxative will be proper. If these fail, chalybeate medicines must be used, such as the tincture of vitriol of mars, steel-silings finely powdered to 6, 8, or 10 grains, or oil of cinnamon with sugar, or bitters, or spaw-waters, with constant exercise.

Of WORMS.

WORMS are various with respect to their shape and magnitude, and have their seat in the stomach and intestines. The round are furnished with a proboscis, and a kind of crooked claws, wherewith they sometimes gnaw and tear the membranes. If these lodge in the stomach, their bites are attended with an inexpressible pain, anxiety, inquietude, nausea, and flux of spittle; a fetid smell exhales from the mouth; the countenance is now pale, and then red; there is an itching of the nostrils, with an inclination to vomit, and a dry and troublesome cough by fits, and sometimes fainting.

When they are contained in the intestines, especially the ilion, then they produce the following symptoms. The belly is strangely distended, especially in infants, and they seem to be afflicted with the tympany, with now and then a diarrhoea, and the faces are of an ash-colour, not unlike cow-dung; the upper parts waste away, inasmuch that the bones are visible, and yet the appetite is great. The face is generally pale and tumid; the excrements seem to be full of cucumber-seed, or the like.

The signs of the ascarides are as follows: Their seat is chiefly in the gross intestines, and they are most plentiful in the rectum. They are like book-worms, and are thrown out in large quantities. They have many things in common with the other insects, and produce inflation of the belly, leanness, and a nausea; they are attended with a great itching of the anus, and cause fetid excrements.

The broad worm, called *tania*, is like a narrow tape two or three ells long or longer, divided through the whole length with cross joints or knots. Andry affirms, that there is only one in the body at a time, and therefore is called *solium*.

The Greeks called the remedies against worms anthelmintics; the most approved of which are *asa-fetida* and *casagapenum*, especially if mixed with purges, such as *mercurius dulcis*, and extract of *rhubarb* in pills; with this caution, that before and after the use of them, a few spoonfuls of salad oil, or oil of sweet almonds should be taken, for all things of that kind are of great use. The seeds of *cina*, *antonium*, and *tansey*, are likewise useful, by resisting the putridous colluvies, and restoring the tone of the intestines.

Some affirm, that bitters are good remedies, as the tops of wormwood, the lesser centaury, scordium, and flowers of *tansey*; likewise *Peruvian bark*, and *eleutheria*, in beer or wine, chiefly canary, in which some spoonfuls of the infusion or decoction should be taken every day. *Aloes*, *myrrh*, and *corallina*, are likewise powerful medicines in a proper vehicle, or with honey, in the form of an electuary. The fresh juice of water-cresses, taken every morning for some days, is likewise proper.

The silings of steel disturb the *lumbri* and *ascarides*; as

also *Spaw waters*; likewise spirit of vitriol or sulphur, and the elixir of vitriol: Wine itself is not a bad thing drank at meals.

Medicines of quicksilver are likewise good, especially half an ounce of it boiled in a pint of wormwood water, in a glass-vessel, for half an hour, stirring the quicksilver with a stick: the dose is a spoonful for a boy, often in a day: an adult may take three, in an ounce or two of solutive syrup of roses; or it may be boiled in milk, if the children prefer it.

If these fail, a purge should be given every third or fourth day; such as *mercurius dulcis*, with *aloes*, *diagridium*, *resin of jalap*, or *troches of alhandal*.

When internal things are rejected, the belly may be anointed with oxes gall made hot, two or three times a day, or with oil of *coloquintida*, or of wormwood, with distilled oils of wormwood and *tansey*, to which the decoction of quicksilver with milk may be added.

To kill the *ascarides*, chalybeates are good, and mercurial purges, with clysters of a decoction of wormwood, seeds of *cina*, *myrrh*, and quicksilver, to which may be added an ounce and a half or two ounces of oil of wormwood made by decoction. Or the clyster may be of salad oil, or oil of sweet almonds, or linseed alone, and injected often.

The powder of tin has been used many years as a remedy against worms, and particularly the flat kind which often elude the force of other medicines; but the success of this depends upon the proper dose, and then it will have remarkable effects.

Take an ounce and an half of pewter, and grind it to a fine powder, and mix it with half a pint of treacle.

To adults give two ounces of the powder of pure tin, sifted through the finest hair-sieve, mixt with eight ounces of treacle, after the patient has been purged with an infusion of *fena* and *manna*.

Of DIFFICULTY or SUPPRESSION of URINE.

DIFFICULTY of urine arises generally from a stone, or from an inflammation of the kidneys or the neck of the bladder. In sanguine persons, it may proceed from the suppression of some usual hæmorrhage, or from the blind piles; or there may be a congestion of blood in the spongy or cavernous part of the urethra, which may be so distended and inflated, as not to transmit the urine, or at least with great difficulty. In some it may be owing to a spasm of the neck of the bladder, or to sharp urine; in others to a palsy of the bladder, or a caruncle of the urethra; or from a tumour, abscess, or ulcer, in the prostrate gland; or from its being too large, or indurated, as often happens. Likewise in bloody urine it is not seldom suppressed; at least it is expelled with great pain and trouble, which proceeds from a concretion of blood. *Etmuller* affirms, that a dysury is generally occasioned from the want of mucus of the urinary passage, or its being worn off.

As the causes of an ischuria are various, they ought to be carefully distinguished from each other. When it proceeds from an inflammation of the kidneys, the pain and heat are principally in that region, attended with a fever; if from a stone in the kidneys, it is accompanied with vomiting; if from a stone in the bladder, there is a violent pain

pain in the bladder, which is extended to the very extremity of the urethra; a mucus or pus is excreted with pale urine; and, upon proper examination, the stone may be felt; but the most certain sign is searching the bladder with a catheter. When this disorder arises from a stone in the urethra, it may be easily felt. If from an inflammation of the neck of the bladder, there is a tumour and pain in the perineum; but it may be best perceived by thrusting the finger into the anus, and turning it up towards the bladder; for a tumour will be perceived by the physician, and by the patient a burning and pressing pain; and when a catheter is introduced into the urethra, an impediment will be felt near the neck of the bladder, which will hinder it from proceeding further. To these signs may be added, when the disorder is great, a tenesmus, a constriction of the anus, an anxiety of the præcordia, coldness of the extreme parts, vomiting, and a freble pulse. When the cavernous substance of the urethra is too much distended with blood, and the urine is suppressed, a silver pipe cannot be admitted into the urethra, especially if the patient abounds with blood. When there is a spasm in the neck of the bladder, it appears from the causes aforesaid; and likewise the patient perceives a spasmodic constriction about the neck of the bladder, and a catheter will pass thereto, but no farther; and there are no signs of a stone in the urethra or bladder.

If the urine is sharp, and produces a spasm, we may discover it from its being very stinking, especially if the patient is old or scorbutic; and there are many saline particles in the urine like lime. When there is a caruncle in the neck of the bladder, it may be known from the signs mentioned in the lues venerea, where the cure is treated of. An abscess in the prostrate gland often is mistaken for a caruncle. When a scirrhus of the prostrate gland is the cause of a suppuration, there is a hard or indolent tumour in the perineum, or at least the pain is not great.

When the urinary passages are obstructed by solid bodies, that is, the pelvis of the kidneys, the ureters, or the neck of the bladder, or the urethra, from a stone contained therein; if it be small, diuretics will be proper, which are mentioned in a fit of the gravel or stone; to which may be added a decoction of eringo-root and Epsum salt or Seltzer waters taken often therewith. But if the stone is large, and cannot be excreted by this means, strong diuretics are highly hurtful, and it must be cured by section; (see SURGERY.) But if the patient is too weak, or too old, and cannot undergo the operation, the stone, if possible, must be driven back; and the pains must be appeased with antispasmodics internally, and with lenients, lubricant and oily medicines, as well as gentle anodynes: Externally, with emollient clysters, ointments, liniments, and baths. If the pains are violent, lenient injections may be thrown up into the bladder, of salad, linseed, and white poppy oil, or oil of sweet almonds, or a decoction of linseed or roots of mallows in milk, with the addition of a little fresh butter. This done, the patient must have recourse to lime-water.

If the urine is suppressed from an inflammation of the kidneys or bladder, diuretics are pernicious, and mineral waters not safe; but rather refrigerating nitrous remedies,

neutral salts, crabs-eyes, tartar-vitriolate, may be given, with a grain of camphor in every dose. To render them more efficacious, they may be joined to a decoction or infusion of parsley-roots, eringo-tea, ground-ivy, or the like; likewise emulsions of the four cold seeds, with crabs-eyes, calx of antimony, and nitre, or seeds of violets, which are laxative and gently diuretic: to these may be added fomentations, and a bladder filled with hot milk or water, or emollient and resolvent cataplasms, applied to the region of the kidneys or bladder, or perineum, according to the place of the inflammation, as well as baths of the same kind: but above all, bleeding is necessary, especially in the plethoric, and the promoting of usual hemorrhages. In the mean while aperients and resolvents must be given, such as powders of crabs-eyes, arcanum duplicatum, tartar-vitriolate, and nitre; or medicinal waters, with bitter cathartic salts given now and then.

When the spongy substance of the urethra is swelled with blood, and as it were inflated, a copious bleeding is the principal remedy.

When a spasm affects the neck of the bladder, it must be treated with temperating and antispasmodic powders, diuretic waters, and infusions, with emulsions, or lenient oils now and then, such as salad-oil, oils of sweet almonds, poppy or linseed: externally, cataplasms, ointments, clysters, and baths, of the emollient and demulcent kind; with gentle opiates, if the disease requires them.

If the spasm proceeds from a sharp urine, from the surry, or otherwise, it must be treated with gentle purges and diaphoretics, and absorbents, such as crabs-eyes, mother of pearl, prepared chalk, calx of antimony, and amber; with lenient decoctions of china root, farfaparilla, or mallows, with emulsions and demulcent oils; to which may be added syrup of marsh-mallows; when the pains are violent, they must be appeased with moderate opiates.

If the difficulty proceeds from blood remaining in the bladder, or its neck, the concretion is to be resolved and expelled with warm infusions of digestive herbs drank like tea, such as ground-ivy, amica, chervil, or veronica; with tincture of tartar, or liquor of the terra foliata of tartar, with digestive powders of crabs eyes, saturated with the juice of oranges or lemons, sperma ceti, tartar-vitriolate, nitre, and cinnaabar: to which may be added the water of chervil or parsley; with roasted onions applied hot to the region of the pubes, perineum; or cataplasms of wheat-flour boiled in milk, with butter and a little saffron, or with white lily roots, mallows, marsh-mallows, or camomile flowers applied to relax the spasm of the neck of the bladder; or with a bladder of hot milk, in which camomile flowers have been boiled; with emollient and resolvent clysters of camomile-flowers boiled in milk, with oil or fresh butter: but, if all these fail, a catheter is to be introduced into the neck of the bladder, to break the concretion, and evacuate the urine.

When there is an ulcer in the bladder, which will appear from purulent and fetid urine, with a most violent pain in the bladder, as if a stone was contained therein; all sharp and stimulating things must be avoided, and the infusions of vulnerary absorbent roots and herbs must be given with mucilages and soft balsamics, especially balsam of Mecca, Tolu, &c. with a moderate use of quicksilver,

especially if the case is venereal. Then mineral waters may be drank, either alone or with warm milk, for several weeks, or the hot bath waters: to these may be added injections of a decoction of the traumatic herbs, such as agrimony, St John's wort, plantain, or yarrow; or, in their stead, milk with syrup of marsh-mallows, or fresh butter, or oil of St John's wort.

If there is a difficulty of urine in pregnant women towards the last months, diuretics must be shunned. The best remedy in this case is to ease the pressure upon the part; but, if that will not do, to use a catheter.

Lastly, if it proceeds from a swelling of the prostate gland, or if it is become scirrhus, it must be treated as such, as will be hereafter taught.

But, if these remedies will not do, the bladder must be pierced with a trochar, which is called the puncture of the perinæum; and, when the perforation is made, the water must be evacuated, as in the dropsy: The instrument must be left in the wound, and be fastened in such a manner that it does not fall out, that so the urine may be made as often as there is occasion: It is a troublesome operation, but the only one left.

Of the DIABETES.

A DIABETES happens when the urine comes away crude, exceeding the quantity of liquids drank, attended with weakness, which generally proceeds from the kidneys, which are too weak and lax, especially in those who have been accustomed to drink too much. *HEIST.*

Lifter observes, that a diabetes comes slowly on, and is a long while in breeding. In the beginning, the mouth is dry, and the spittle a little white and frothy; the urine being somewhat more than usual, with a small thirst. A heat begins to be perceived in the bowels, which is a little pungent; the patient falls away, and the mind is anxious and unstable. In time the thirst greatly increases, the urine is plentiful, and the body wastes. When they make water without intermission, the thirst becomes intolerable; and, though much is drank, it is not proportionable to the water. When the urine is retained a little while, there is a swelling of the loins, ilia, and testes, and it comes away with pain. Now death is at hand. The urine is pale, not sweet, but it is more sweetish at last than at first.

Strengtheners, moderate astringents, and species of hyacinth, with crocus martis, are good in this disease, especially with anodynes: or Japan earth, or the tincture of vitriol of mars, red wine with water in a small quantity: the drink should be sparing, and all excesses avoided. Exercise and frictions of the body are likewise profitable, because they strengthen the parts, and increase perspiration.

Lifter says, almonds and a milk diet are proper in this distemper; as also wine with ginger; allowing in the mean time a draught of milk and water to allay the thirst.

Willis declares, he has often prescribed tincture of antimony with good success; and lime-water with assafras, aniseeds, raisins, or liquorice.

OF WOMENS DISEASES.

Of the CHLOROSIS, or Green-Sickness.

SYDENHAM looks upon this to be a species of the hysterical affection, and is known by a paleness and discolouration of the face and the whole body. The complexion appears a little sallow or greenish, with a red or dark circle under the eyes; the face is bloated, the eyelids and angles are apt to swell; the whole body is heavy and dull; there is a tenive lassitude of the legs and feet, difficulty of breathing, palpitation of the heart, pain of the head, a feverish pulse, a drowsiness, a pica, or desire of eating unfit things, such as coals, chalk, &c. and a suppression of the menses. The clavus hystericus often attacks patients in the height of this disorder.

The cure is to be attempted with chalybeate medicines, such as are prescribed in the hysterical disorder, given according to the patient's age, drinking wine after them; or the corroborating infusion with angelica root. If the patient is not very weak, she may be purged once or twice before the course is entered upon.

Heister recommends attenuants, evacuates, and strengtheners, with a good diet and exercise; particularly from v to viij grains of powder of steel, with half a scruple of a proper elæosaccharum, or with bitter extracts given in the evening; as also emmenagogues at due times, with pediluvia and bleeding in the foot about the time of menstruation. If these will not suffice, he thinks matrimony a certain cure.

Of the SUPPRESSION of the MENSES.

As soon as a healthy female arrives at her full growth, she generates more blood than can be conveniently contained in the vessels; wherefore the superfluity is evacuated by the uterine arteries, and is called the *Menses*.

Boerhaave observes, that in a suppression of the menses there is a plethora, with a lightness to motion; a heaviness, a paleness, a pain of the loins and of the groin; all the functions, whether natural, vital, or animal, are depraved. Sometimes the menses will force a way thro' the eyes, ears, nostrils, gums, the salivary ducts, bladder, breasts, skin, wounds, or ulcers.

Hence often arises a deprivation of all the viscera, as also diseases without number, partly from a putrefaction already begun, and partly from the hurt which the vessels have received.

From this disorder proceed want of appetite; the pica and malacia, or a depraved appetite. If it is habitual and obstinate, a scirrhus or dropsy of the womb are to be feared, or a rupture of some blood-vessel, especially of the lungs. It is not so dangerous when the uterus is not infarcted, or when there is no other symptom of the menses. If this disease is attended with the fluor albus, it may become habitual, and from yellow become green and acrid, corroding the uterus, and laying a foundation of a dropsy therein.

Things which retard the menses are, immoderate cold, sorrow, a sudden fright, too great evacuations, incrustation

ting diet, a crudity of the humours, acids, and astringent medicines.

This disorder is to be cured in the same manner as the hylicer affection; but, if the remedies for that fail, the patient must take every morning five spoonfuls of an hylicer julep, with twelve drops of spirit of hartshorn; and every night a scruple of compound powder of myrrh made into a bolus, or pills with syrup of lemons. Allen recommends cantharides and camphor; the dose is from two grains to six.

Hoffman directs chalybeates, or pills made of aloes, myrrh, saffron, amber, castor, and round birthwort. Pitcairn thinks mercury more efficacious than steel.

If the fluids are inclinable to stagnate, their fluidity may be preserved by fomentations and frictions of the feet; by opening a vein in the foot, and bleeding elsewhere; by giving uterine purges; by emmenagogues; by plasters, fomentations, liniments, vapours and heat; by strengthening the vessels debilitated with a plethora, by chalybeates and astringents.

Uterine cathartics are aloes, myrrh, bryony, colocynthus, gum-ammoniac, bdellium, fagapenum, opopanax, asa fetida, galbanum, and elixir proprietatis.

Emmenagogues, besides the former, are, aristolochia, mugwort, motherwort, camomile, juniper, marjoram, marum, feverfew, pennyroyal, rue, savine, sage, elder, wild-thyme, tanfy, thyme. To which may be added balm, rosemary, wall-flowers, saffron, bay and juniper berries, amber, rhubarb, and aromatics. As also borax, alkaline and volatile salts; warm, stimulating, acrid, and aromatic oils; the barks of guaiacum, sassafras, cinnamon, and juniper; the rinds of oranges, citrons, and lemons.

Resolving plasters are those of cummin, melilot, galbanum, bayberries, labdanum, oxycroceum, which must be applied to the soles of the feet, navel and groin. The fomentations may be made of Venice soap, and some of the above mentioned herbs.

Of the IMMEDIATE FLUX of the MENSES, or Uterine Hæmorrhage.

EVERY large flux of blood from the uterus is not to be esteemed noxious, but such only as is attended with loss of strength, which brings on other symptoms, such as want of appetite, crudities from indigestion, a sensation of weight near the region of the stomach, an ill colour in the face, a languid pulse, often with a gentle heat, an œdematous swelling of the feet, and a disturbed sleep without refreshment.

Sometimes the menses flow in too great plenty and with impetuosity at the usual period; sometimes twice or oftener in a month; sometimes again they continue several days longer than ordinary.

This flux sometimes consists of thin florid blood, which happens chiefly in abortions; and from a retention of pieces of the secundines, which keep the mouths of the vessels open. Sometimes there are coagulated and clotted masses like flesh come away with the blood, of the size of an egg, which is occasioned by a stoppage of the menses for two or three months. At other times the blood is grumous, coagulated, and black; generally on the first

days of child-bed, in slender and plethoric subjects. When the patient is cachectic, and the flux continues long, it is thin, watery, and mucid. In the scorbutic, it is corrupt and fetid, with acrimony and pain. In the younger sort, before child-bearing, if the evacuation be immoderate, it is commonly followed by a flux albus, or the dripping of a white, impure, mucid matter.

The cause may be referred to a copious and impetuous afflux of blood to the uterus, and an unequal and impeded reflux by the veins; which distending and relaxing the uterine vessels, make the orifices too wide, or rend and corrode them, by which the blood flows too freely. This may happen from a plethora, or when there has been a long suppression, or an abortion, or a difficult labour. It generally happens to women about the fiftieth year, when the menses are going to leave them; and not always without danger. It sometimes happens to women upwards of sixty, which, if attended with a slow fever, hastens death.

The concomitant signs are generally these: A tension and inflation of the hypochondria, a heavy pressing pain about the loins, sometimes with a chilnests; a coldness of the extremities, a sinking of the vessels, a paleness of the face, a quick pulse, with an internal heat, a costiveness, and little urine; all which shew there is not only a debility and laxity of the uterus, but spasmodic strictures of the vascular and nervous parts, which force the blood to the uterus.

If the body is cachymic or scorbutic, or full of bad humours, or afflicted with the venereal disease; when the viscera are unsound, and the liver, spleen, and meseraic veins, are stuffed with thick blood, the case is dangerous and troublesome; for the fault of the fluids and cachexy continually increase. Besides, the more the strength is weakened, the more the stomach and digestion are hurt; the blood is depraved, and the excretions disturbed and lessened. When this happens to women when the child is dead, their lives are in great danger, and nothing but speedy assistance from a man-midwife can save them. The case is also dangerous when the secundines are violently extruded, or parts of them are retained, and which sometimes degenerates into moles.

Immoderate evacuations are produced by a sedentary life, which gives room for abundance of thick chyle and milk. It is caused likewise by too frequent use of salt, acrid, and seasoned meats; by spiritous liquors, &c. by violent agitations and passions of the mind, from losses, gaming, love, anger, &c. It may be observed likewise, that violent exercise does as much harm as the moderate is serviceable, especially if the patient is subject to this flux from other causes; such as immoderate repetitions of the venereal act, especially in women of a delicate constitution; too frequent child-bearing.

The cure should respect the restraining a present flux, and the keeping within bounds a future one.

It should be begun with rest, if convenient, in bed; the patient lying on her back, and silent as much as possible. Bleed in the arm, according as the constitution and strength of the patient, as well as the urgency of the symptoms, will admit or require. Avoid ligatures of the limbs. Let the patient fare slenderly on veal and chicken-broths,

broths, fish-soups; and drink a pisin of nettle-tops, yarrow, and plantane, with orange-peel, or of the greater comfrey: if she be hot and bilious, with linseed.

If these fail, have recourse to altringers.

Of the FLUOR ALBUS, or Whites.

The fluor albus consists in the efflux of a whitish, lymphatic, serous, or aqueous humour, from the matrix.

It is sometimes white, sometimes pale, yellow, green, or blackish; sometimes it is sharp and corrosive, sometimes foul and fetid: the face is discoloured, there is a pain in the spine of the back, the appetite is lost, and the eyes and feet swell. Some women have a periodical flux of the whites instead of the menses.

The symptoms are, a pain and weight in the loins, which is worst in the lymphatic flux, as being attended with a swelling of the uterus, turbid urine, barrenness, a proneness to abortion; a loathing of some things, and longing for others; indigestion; thickness and crudity of the blood; whence proceed cedematous swellings of the feet by day, and of the face by night; difficult breathing, palpitation of the heart, syncope, relaxation of the ligaments of the uterus, a total or partial procidentia uteri: if the flux is acrid and corrosive, it ulcerates the vulva; creates phlyctenæ; which last generally proceed from a scirrhus or cancer in the uterus; a slow fever; dropsies of different parts; of which, or a consumption, the patient generally dies.

It may be known from a virulent gonorrhœa; because this is attended with pain and an inflammation of the external parts of the pudenda, chiefly about the clitoris; heat, sharpness and difficulty of urine, pain in coition; it makes its progress sooner. If the gonorrhœa is inveterate, it is very like a fluor albus.

Besides arterial blood, the menses consist of redundant lymph or serum, chiefly from the membranous cells, and ventricles of the glands of those parts of the membrana cellulosa which are more immediately connected with the kidneys, uterus, and ovarium. When this lymphatic secretion becomes morbid, it is called the fluor albus. At first the parts of the membrana adiposa of the loins, kidneys, and uterine appendages, are wasted by it; but at length the flux becomes acrimonious, and may melt and carry off all the fat of the body.

The fluor albus sometimes is discharged from the uterine vessels, and sometimes from the glands of the vagina: in the first case it stops when the menses begin to flow; in the latter it continues with them, and pregnant women are not exempted from it.

When this flux is unseasonably stopped, it causes the belly to swell, with pains of the loins, slow fevers, numbness of the joints, and great lassitude of the body.

When the flux is lacteous, it may be cured in fifteen days. The patient must feed sparingly, use frequent exercise, and sleep little. If this is not complied with, she must bleed in the arm once or twice a-month, and take purges and emetics, or at least frequent clysters. The efficacy must be assisted with diaphoretics, decoction of the woods, and diuretics.

In the femilacteous flux, inspissating and nourishing diet will be best, such as creams, soups, boiled milk,

roast meat, jellies, &c. milk, or milk turned with a decoction of china, is very good.

Narcotics are highly useful, especially if the patient is restless, or delirious. In the beginning the dose must be small, which may be gradually increased.

When the vesiculæ lacteæ are relaxed, the tone must be restored with hot mineral baths, fomentations and injections of and bathing in the same. The stream may also be conveyed into the vagina with a funnel.

Decoctions of the woods are also good as diaphoretics; and diuretics of a decoction of roots of eringo and rest-harrow, with powder of millepedes, or glauber's salt.

If the lymphatic flux is attended with a scrophulous, scorbutic, or venereal taint, these disorders must be first removed. If the uterine lymphatics are compressed by scirrhoties, cancers, ganglions, or the like, regard must be had to the causes,

In obstructions of the glands of the uterus, begin with bleeding; then a gentle purge, or an emetic of iij grains of tartar emetic or ipecacuanha. Afterwards, if the patient's constitution is cold, attenuating aperients. If she is hot and bilious, with a sensible pain in the uterus, cooling broths and apozems, with the addition of crayfish; asses milk, with a decoction of barley; chalybeate whey, with chervil boiled therein. Gently purging mineral waters, baths, and half baths, are convenient in the summer.

Of the FUROR UTERINUS.

SALACITY in women, attended with impudence, restlessness, and a delirium, is called the *furor uterinus*.

It arises from a too great sensibility or inflammation of the pudenda, or parts wherein the venereal stimulus resides, which are chiefly the clitoris and vagina; or the too great abundance and acrimony of the fluids of those parts; or both these causes may exist together.

In the delirium maniacum, the patient is entirely shameless; in the melancholicum more reserved, and her folly is confined to fewer objects.

It may proceed from the abuse of hot aperitives; thus sal amoniack, borax, and cantharides, have produced it: from powerful emenagogues in hot and bilious constitutions; sometimes from difficult and suppressed menses; from remedies given against sterility. Musk dissolved in oleum aromaticum, and rubbed on the membrum virile, has raised a phlogosis in the vagina, whence a furor uterinus ensued.

It is difficult to cure in those whose menses are difficult at first; in inveterate cases; in old subjects. It is easier cured, when the furor uterinus is essential, and the delirium symptomatic, than when the delirium is essential, and the furor symptomatic. The maniacal delirium is harder to manage than the melancholic. If it continues a month or two, the fault of the brain becomes obstinate, for it degenerates into real madness.

The indications of cure, are to diminish the heat and sensibility of the affected parts; to cool, sweeten, and dilute the blood, and to render it balsamic; or to pursue both intentions at once.

The first indication is answered by frequent and copious bleedings, as in an incipient madnes; even to eight times

in two days, if nothing forbids; if the faints, there is no danger. She must likewise be purged, as mad folks are, with jalap, scammony, diagrid. The dose must be increased one third, as being hard to purge. Emetics are also good; for they evacuate the bile, which abates the acrimony of the humours. In the intervals, order frequent emollient clysters; to which add half a dram of sal prunella, or a little vinegar morning and night, baths and semicupia; moderate the heat, irritation, and sensibility of the parts affected: as also emollient injections into the vagina, and fomentations, or pessaries of cotton may be steeped therein; sal prunella may also be mixed therein.

Of an INFLAMMATION of the WOMB.

An inflammation of the uterus appears from extraordinary heat, and a fixed pain in the groin, with an acute fever, a pain in the loins and belly, an inflation of the abdomen, a stimulus to make water and go to stool; heat, and difficulty of urine; tumour, pain, heat, and tension of the hypogastric region; redness of the os uteri, and great heat of the vagina. If the fore-part of the uterus is affected, there is a dysuria or heat of urine; if the back part, a tenesmus, frequent faintings and cardialgia, a burning fever; or, if the inflammation is violent, a lyp-pyria, in which the external parts or extremities are cold, and the internal burn, and the pulse is imperceptible; a delirium and phrensy: the breasts swell in proportion as the inflamed uterus.

This disease may be said to be superficial or more grievous and profound. It is easy formed in child-bed women, and frequently accompanies the milk-fever; and may be cured in a few days, if rightly managed: But when it is very intense, and attended with grievous symptoms without remission, it kills on the seventh, ninth, or eleventh day; and a white milky fever generally supervenes, which is the worst omen, for it shews a mortification of the uterus. When this fever happens, there are spastic and painful strictures in the abdomen, the flux of the uterus is stopped, the body is costive, the feet are cold; there is an urging to make water, which is painful; the head looks red, and swells; the eyes shine; drops of blood fall from the nose; the mind is disturbed; the sleep is little, with terrifying dreams: there is likewise most difficult breathing, faintings, convulsions, a phrenetic delirium, which commonly have a fatal tendency.

This disease should be distinguished from an inflammation of the bladder or rectum; which may be done from the place of the pain: in that of the bladder it is superficial, as if it were in the integuments; in that of the rectum it is very deep, as if about the os sacrum; in that of the uterus it is in the middle, with a violent heat in the vagina, if the finger is introduced. If the bladder is affected, there is an extraordinary heat and retention of urine; and a tenesmus, if in the rectum: In the bladder; the pain is precisely on the os pubis; in the rectum, the anus is affected. If these symptoms happen in an inflammation of the uterus, they are more slight.

If the inflammation is not resolved, it generally ends in a mortification, ulcer, or cancer. A mortification soon

kills, and the womb and vagina after a dissection appear to be of a blackish brown. If it ends in a suppuration, the disease is of longer date, which generally happens to women not in child-bed: It begins to discover itself about the ninth or tenth day, by the cessation of most of the inflammatory symptoms, which will return about the twelfth with a shooting pain in the affected part.

A gangrene or mortification happens on the fourth or fifth day, and is known by a weak, languishing, and intermitting pulse, and by a sudden cessation of all the symptoms.

If the disease exceeds the time of the former terminations, and the inflammation is superficial, it is apt to turn to an induration or scirrhus; which ulcerating, becomes a cancer, and is incurable. If, about the twenty-second day, there is a renitency or hardness, and a dull heavy pain in the region of the uterus, there is a scirrhus formed.

Women in child-bed sometimes have the womb inflamed from the fault of unskilful midwives, or hard labour; or the lochia are stopped by pains, or hysterical spasms, dread, or cold; wherefore proper precautions should be used to prevent it; which may be done by keeping them under a gentle diaphoretic regimen, and by allaying the almost febrile heat. Oil of almonds is proper alone, or with a fourth part of sperma ceti, given daily to half an ounce in chicken-broth; externally the whole abdomen should be anointed with oil of dill, camomile and white-lilies, of each an ounce, oil of caraways a dram, or a dram of camphor; laying a warm napkin doubled over the same.

The tumult being thus appeased, the lochia are to be promoted with pills of bitter extracts, temperate resinous gums, and aloe well corrected, of which xv gr. is a dose morning and evening, to be continued from five to eight days. These are also good when the after-birth or part of it is retained.

If there is a fever, the belly is distended with wind, the lochia are retained, and the spasms tend to the upper parts, you must bleed in the foot.

The drink may be chicken-broth, with scorzonera root, succory, and shavings of hartshorn boiled therein. As also temperating and resolving powders made of crabs-eyes, and their solution. nitre, and sal polychrest. To which may be added clysters of whey, camomile-flowers, mug-wort, sage, &c. with honey, nitre, and fat of hens.

In women out of child-bed the inflammation generally happens in the neck of the uterus and the vagina; and then, besides the foregoing things, you must apply epithems to the pubes, uterine injections, pessaries, and suppositories. The epithem may be of arquebuse water four ounces, essence of saffron, camphorated spirit of wine, of each two ounces, nitre a dram, dissolved in elder-flower water; and, as circumstances require, mixed with vinegar, or rue, or scordium, and applied with a double cloth. The injection may consist of asses milk, with flowers of elder, myrrh, and saffron; and a little nitre may be added to the decoction. The tenesmus may be appeased with emollient half baths, or with an ounce of oil of sweet almonds, and xij grains of saffron, injected into the anus. These remedies are useful in case of a suppuration.

Of the Abscess of the Womb.

ABSCESSSES of the womb are either inflammatory, tuberculous or steatomatous.

The symptoms of an incipient abscess are much the same as the inflammation, such as pain, heat, tension, &c. which intermit for some time, and appear again, when the suppuration begins; of which the inflammatory is most sensible, the steatomatous the least. When the abscess is formed, all the symptoms of inflammation vanish; but coldness of the extremities, a slow fever, and marasmus, gradually increase from the absorption of the pus into the blood.

If no inflammation has preceded, and the patient was subject to obstructions, especially of the glands of the uterus, and had a lymphatic fluor albus, it may be tuberculous; if the tumour is soft and indolent, it may be steatomatous; but these are rare. The place may be partly discovered by the touch, but more especially by the complaints of the patients.

If it breaks into the bladder, and passes off by urine, or into the rectum, and is discharged by stool, or into the groin, it is dangerous; if into the abdomen, incurable: If it breaks into the vagina, it may become an ulcer, which is commonly mortal; or the patient may perish by a hectic fever before the eruption. The tuberculous and steatomatous are much the slowest.

The work in this case must be left to nature, in a confirmed abscess; unless it can be come at through the vagina, and opened with a lancet, and then detensive injections may perform a cure.

Of the Ulcer of the Uterus.

AN ulcer may have its issue and seat in the concave surface of the uterus; or may be lodged more deep, and have issues into the rectum, bladder, groin, or cavity of the abdomen.

The causes of an erosion may be the fluor albus, or rather lymphaticus; the corruption of the fetus, or placenta, in the womb; acrid or caustic injections; the frequent use of cantharides, the lues venerea, or acrimonious menses.

If the ulcer proceeds from an abscess, it may be inflammatory, tuberculous, or steatomatous; if from an erosion, it may be venereal, scorbutic, scrophulous, or simple: It may be also simple, scirrhus, or cancerous.

The chief sign of an ulcer is the efflux of purulent matter; and the greater the quantity, the profounder the ulcer. If the flux is sanious, or mixed with blood, the blood-vessels are eroded. Mortal hæmorrhages sometimes supervene. Sometimes they may proceed from a fever, and rarefaction of the blood.

An ulcer is hard to be distinguished from a fluor albus; however pus is always more compact and fetid, unless it is lymphatic; and there is always a fixed pain from an ulcer.

All ulcers of the uterus are dangerous; when they are fistulous, or scirrhus, or both, they portend death: the same may be said of the cancerous; or when they are attended with a slow hectic fever, swellings of the feet, a marasmus, &c.

In order to the cure, it is necessary to know whether the ulcer is seated in the body of the uterus, or near the os uteri, in the vagina; or whether it be venereal, for the last must be treated as that distemper requires.

To correct the vicious acrimony of the blood, use broths, or decoctions of lettuce, succory, sorrage, with sal prunella; sometimes with veal or a pullet; also chalybeated whey, sweetened with syrup of violets. But the best thing is a milk-diet; to which, for variety's sake, may be added rice, eggs, a decoction of china, barley, &c. or chervil, agrimony, fumitory, or the second lime water, or steel waters alone. Likewise emollient baths or semicupia.

Injections of whey and brown sugar are good.

To consolidate the ulcer, use injections of agrimony, with the second lime water; or warm sulphureous bathwaters, and the fumigations of the gums.

To ease the pain, give gentle narcotics.

Of the Scirrhus of the Uterus.

SOMETIMES an inflammation of the uterus ends in a scirrhus, which is a hard, rentent, and indolent tumour, without heat and pain.

It is a very troublesome disorder, and often incurable, and the attempt to remove it is dangerous, though it is apt to bring on dropsies, a cancer, a marasmus, &c. Its seat is in the glands, lymphatic vessels, or lacteals of the uterus.

The symptoms are, a weight in the hypogastrium, when the patient stands or walks; difficulty of lying on the well side; if the tumour is painful, she is obliged to lie on her back; the menses are suppressed; sometimes there are violent and dangerous hæmorrhages; a dropy of the abdomen or uterus: If it suppurates, there are signs of an abscess. It may be partly discovered by pressing the hand on the region of the os pubis.

If the tumour be small, recent, and void of pain, you may give broths of eringo, rest-harrow, and asparagus roots, of each half an ounce. Whey, with vitriolate tartar, or chalybeated whey, are very gentle. Or give a pint every day of vitriolic waters, for two or three months.

If these heat too much, the most drink asses or goats milk. This is a palliative cure. But, to dissolve the scirrhus matter, the patient must use baths, and half baths, of emollient decoctions. Emollient injections and moderate clysters are very beneficial.

When heat, pain, and tension of the uterus are perceived, forbear decoctions, and bleed. Use no aperitives at the time of purging. At other times use diluents and narcotics. If the tumour does not diminish, leave these medicines off, and have recourse to the palliative cure.

Of the Cancer of the Uterus.

A CANCER is a scirrhus become exquisitely painful. When there is a darting or lancinating pain in the scirrhus, and in fifteen days or a month it becomes much larger than it was before, and scabrous, that is, angular and rugged; and the skin that covers it is smoother, till a fissure appears; the lips of which are retorted, and an ichor or acrimonious serosity proceeds therefrom,

with

with a soft fungous flesh about the fissure; you have the progress to a confirmed cancer. The matter never becomes pus.

An ulcer of the uterus resembles a cancer, when a putrid sanies issues from the corrupted substance of the womb, with great stench, exquisite pain, and grievous symptoms. This disease is almost incurable.

The principal symptom of a cancer is pain, which is attended with restlessness, watching, indigestion: which produce a slow fever, consumption, marasmus, and the like.

A hard, renitent, painful tumour, preceded by an indolent scirrhus, plainly evinces the existence of a cancer. If nothing is discharged by the uterus, but a limpid, pellucid lymph, it is an occult cancer; if acrid serum, or ichor, it is open.

There is nothing to be done in this case, but by demulcents and lenients. If there is any hope of cure, it must be placed in asses milk, the Selters waters, and in bathing in soft water wherein wheat bran has been boiled; in which the patient must sit for an hour, or longer. She must abstain from all sharp, acrid, stimulating, and heating things.

Of the PROCIDENTIA UTERI.

It is a common disorder; and the uterus presents itself in the vagina between the labia, or is quite visible. Sometimes it is only the internal membrane of the vagina, sometimes the body of the womb.

This disorder is rarely dangerous, for women bear it a long time.

The cure consists in reducing the uterus, and retaining it in its place. To reduce it, order a simple clyster to evacuate the rectum; the patient should also bleed three or four times: Then emollient cataplasms should be used of white bread and milk, or of emollient plants: emollient baths are also to be employed. The parts being thus relaxed, the patient must lie on her back, with her hips higher than her head, and her legs quite asunder; then put back the uterus by degrees, where you find the least resistance, and without any violence. This done, the patient must be confined to her bed for about fifteen days, with her thighs closed, or her legs across, and her hips raised.

The cure must be compleated with astringent injections, baths, and pessaries; with fumigations of frankincense, red roses, and mastic.

For ABORTIONS, }
For CHILD BIRTH, } see MIDWIFERY.

OF CHILDRENS DISEASES.

Of Disorders from a Retention of the Meconium.

INFANTS newly born, from a retention of the meconium and other fordid matter in the *prima via*, are subject to gripings or pains in the belly, which produce constant crying, hiccups, the jaundice, wakefulness, restlessness, startings, frights, convulsions, and epilepsies; which, unless timely prevented, are fatal.

To carry this off, infants should suck the first milk of their mother, if they give suck; otherwise they should

fast ten or twelve hours; or take the following mixture, which will soften it:

Take 6 drams of fresh milk whey, and one dram of honey; make them into a draught.

Heister advises a grain or two of the powder of jalap, or two or three of rhubarb in syrup of roses solutive, or a solution of manna; some give half an ounce of oil of sweet almonds, with a little barley-sugar. A grain of aurum fulminans is the surest remedy.

Of Disorders from Costiveness and Wind.

If after some time the excrements become hard, with costiveness and a retention of wind, they will cause the symptoms abovementioned. In this the same remedies may be used, till the child's belly is open, and the acid or corrupted milk should be corrected with absorbent and testaceous powders; whereof half a scruple is a dose. Harris believes an acid to be so predominant in infants, as to cause all their diseases. Boerhaave affirms, if absorbents are useful at any time, they must be in these cases, and orders *vij* grains of the testaceous powders three times a day.

The nurse must forbear to feed upon any thing that is sour or acid.

Of WATCHING, or Want of Sleep.

WANT of sleep proceeds from the gripes, or costiveness, and wind and pain occasioned thereby: we judge of the health of children by their sleeping quietly, and of their illness by their watching, crying, and screaming. Watching may proceed from the milk being corrupted in the stomach, or from costiveness, or from wind.

In this disorder the body should be always kept open, first by a clyster, and then a purge; and the absorbents are to be given, and carminatives, particularly powder of aniseed; and the belly is to be anointed with carminative oil. Soon after the purge, give two drams of oil of almonds. The nurses should avoid acid and stautent things, and catching cold. Opiates, disacordium, and theriaca, must never be used, unless in cases of extreme necessity.

Of the APHTHÆ or Thrush.

THE aphtæ are little whitish ulcers affecting the whole superficies of the mouth, that is, the lips, gums, cheeks, tongue, palate, and fauces; nay, they even descend through the œsophagus to the stomach and intestines, and to the anus but then they are very dangerous, and commonly put a period to the infant's life.

Boerhaave says, if the aphtæ are of a pearl-colour, pellucid, white, few in number, superficial, soft, and fall off easily, apt to return in part, they are of the best sort; but if they are white or opake, like bacon, yellow, brown, black, thick, dense, running together, hard, tenacious, constantly restored, corrosive, they are bad.

Harris believes gargles to be of little service, because infants cannot use them, inasmuch as they swallow every thing that is put into their mouths. He therefore relies for a cure on the testaceous powders, and the most gentle cathartics, and believes them sufficient.

Allen says the decoction of elm-bark is the best gargism for the cure of the aphtæ.

This

This disease often attacks **ADULTS** in acute diseases and inflammation of the viscera. Boerhaave observes they are most common among the northern people, that inhabit low marshy places, and often attend a continual putrid fever, or an intermittent becoming continual; and that they are ushered in with a diarrhoea, or a dysentery, a nausea, vomiting, loss of appetite, great anxiety about the præcordia often returning, some great evacuation of the fluids, a stupor and dulness, sleepiness, a perpetual complaint of weight about the stomach.

To cure this distemper, hot, diluting, resolvent, and detergent medicines must be given, that the crust may be dispoled to fall off easily.

Huxham advises, when the aphthæ supervene in fevers, to use gargles frequently of emollients and detergents, made with figs, hydromel, decoction of turnips, &c. To give rhubarb inwardly, chiefly if the patient is griped and loose, adding an aromatic alstringent with absorbents.

Of GALLING and EXCORIATION.

THERE is often an excoriation of the parts near the pudenda, chiefly of the groin and scrotum; in the wrinkles of the neck, under the arms, and in other places, proceeding from the acrimony of the urine and sweat. From this proceed itching pains, crying, watching, and restlessness.

To remedy this, the parts affected may be washed often with warm water, and sprinkled with drying powders, such as chalk, burnt hartshorn; but especially tutty, and cerufs, which may be tied closely in a rag, and the powders shook out on the disordered places,

If the parts affected are more sore, and tend to a real ulceration, it will be proper to add a little saccharum saturni to the powders. Likewise a little white vitriol dissolved in spring water, and daubed upon the part, will dry and heal it very powerfully.

Of the STOPPAGE of the NOSE.

THE nostrils of infants are often plugged up with a gross mucus, inasmuch that they can scarce breathe, or suck, or swallow; which renders them very uneasy and uneasy. To cure it, after a suitable purge, dissolve two or three grains of white vitriol in half an ounce of marjoram water; then filter it, and apply it now and then to the nostrils with a linen rag.

Or you may apply oil of sweet almonds; impregnated with the oil of marjoram, to the bottom and sides of the nostrils, which will resolve the filth, and render the respiration free.

Of the SCABBY ERUPTIONS and CRUSTA LACTEA

THE heads of children are often troubled with aches or scabby eruptions; and if the face is affected with them, they are called crusta lactea. These are expelled by the benefit of nature; and, before the eruption, the infant is often troubled with epileptic fits from the irritation of the morbid matter.

If the humours strike in, either spontaneously or by improper applications, or if the exanthemata are of a blackish colour, they are very dangerous, and the infant generally falls into an asthma or a fatal epilepsy.

In the cure, externals, and especially such as are repellent, should be avoided; and things should be given inwardly which correct and temperate the blood, and expel the noxious matter by a diaphoresis. After the *prime viæ* are purged, both the nurse and child should take alexipharmics in the morning, and the testaceous powders with calx of antimony, amber, and cionabar, in the afternoon.

Externally, nothing of sulphur or mercury should be applied, or repellent lotions, or any thing cold. To mollify the scabs, fresh butter, or calves marrow, or cream, are sufficient. This case often proves obstinate; and then the nurse should observe a strict regimen, use good diet, take sweeteners of the blood, and purgatives now and then.

Of a DIARRHOEA and VOMITING.

THE diarrhoea of infants is not to be stopped, either with astringents or narcotics: For astringents turn the flux of sharp humours towards the noble parts, and endanger the life of the child; and, though narcotics appease the ferocity of the turbulent humour for a time, yet they afterwards break out with greater force. Besides, opiates are too powerful for the tender constitution of infants, and must not be given at all, or with the utmost caution. In slight cases, diaacordium may be ventured upon, to five or six grains; but, if there is a fever, it cannot be given without danger.

Therefore the best way is to give chalk, coral, pearls, and the like, of which about half a scruple is a dose; which will abate the organic of the humours, without kindling any new heat: after which the cure may be completed with rhubarb, from six grains to half a scruple, in solutive syrup of roses.

With regard to VOMITING, if there is great plenty of ferous and noxious humours in the stomach, inasmuch that the stomach can retain nothing, if the child is a year or two old, he may safely take some grains of ipecacuanha; Harris says xv. but surely a third part of that quantity, nay, one or two grains, may be sufficient; for this does not require the swallowing so much liquor after it as some others; and yet clears the stomach of crudities, viscidities, and other bad humours.

Of Difficult BREEDING the TEETH.

AMONG all the disorders which afflict children, there are none that generate such grievous symptoms as difficult dentition. About five or six months after birth, the teeth generally begin to make their appearance; first the incisors, or fore-teeth; next the canini, or dog-teeth; and lastly, the molares, or grinders. About the seventh year there comes a new set; and at twenty-one the two inner grinders, called dentes sapientie.

At the time of cutting their teeth, they suffer very much, and have a diarrhoea, which is no bad sign; but when it is difficult, especially when the canine teeth begin to be in motion, and to make their out-way out through the gums, the child has startings in his sleep, tumours of the gums, gripes, inquietude, watchings, a looseness or colicness, greenish stools, the thrush, fevers, difficult breathing, suffocating catarrhs, convulsions, epilepsies, which often end in death.

It shews dentition is like to be bad, if the child is perpetually crying, thrusts his fingers into his mouth, and bites the nurse's nipples; if unequal tubercles are perceived in the gums, both by the sight and touch, where the teeth are expected to appear: if there is heat in the mouth and the whole body; if they start without a cause, especially in sleep. These do not come on without great flaving, and sometimes a diarrhoea, as was mentioned above.

Harris observes, that, when an inflammation appears, the physician will labour in vain, if the cure is not begun with applying a leech under each ear. When the swelling of the gums shews it is time to cut it, to make way for the tooth, he would have it done with a penknife, not with a fine lancet, lest the wound should heal, and form a cicatrix. The food he directs to be no more than luke-warm.

Heister internally advises aqueous mixtures, tempering powders; externally, oil of sweet almonds, with syrup of violets, or syrup of wild poppies, lightly acidulated with spirit of vitriol, wherewith often to rub the gums; as also with the coral or other smooth things, which will have the same effect.

Morgan affirms in this case, it will be best to abate the effervescence of the blood with diluters; to appease the pain with gentle opiates; to open the body with purges and clysters; to draw off the fermented serum by blisters; to promote the cutting of the teeth by cooling, relaxing, and opening the gums; for this purpose diacodium is good; or a strong decoction of marsh-mallows and poppy-heads, in thick milk, cream, or neats-foot oil: These take off the heat, and assuage the pain.

Of the RICKETS.

CHILDREN are seldom attacked with rickets before they are nine months, and after they are two years old; but it frequently happens in the intermediate space between these two periods. It may proceed originally from the disorders of the parents, and may be increased by those of the nurse.

It is like wise promoted by feeding the child with aqueous and mucous substances, crude summer-fruits, fish; by unleavened farinaceous aliment, and too great a quantity of sweet things; by an intermittent autumnal ague, or other chronic or acute disorders; by a striking in of the itch or herpes; by the suppression or injudicious cure of ulcers; by being enervated with baths, fomentations, ointments, or moist vapours; by continual rest in a perforated chair, with his coats up.

This disorder is known, in those who cannot walk,

from the causes preceding; from his brothers or sisters having the same disease; from a flaccid tumour of the head and face; from a flabby loose skin; from a swelling of the abdomen; from a falling away of the rest of the parts, especially of the muscles; from protuberances of the epiphyses of the joints, such as the wrists, ankles, knees, elbows, &c.; from the magnitude of the jugular veins and arteries, while the rest decrease. The legs grow crooked.

In those that have begun to walk, besides the former signs, there is a slowness, debility, and tottering in his motion; which soon proceeds to a constant desire of sitting, and afterwards changes to lying down; inasmuch that nothing at last is moveable, but the neck and head. Add to these, an early wit, an understanding which exceeds his age, while the appetite and digestion continue unhurt.

As he grows older, his head is enlarged, with ample sutures; his thorax is compressed on the sides; and his sternum rises up sharp, while the extremities of the ribs are knotty. The abdomen is protuberant, and the teeth black and carious. These disorders sensibly increasing, are the cause ever after of pernicious diseases of the same kind; principally a spina ventosa, and a caries of the bones.

In the mean while a slow feverish disorder preys upon the whole body, till the time of death; and then all the fibres, vessels, and viscera appear to be soft, flaccid, and the fluids dissolved and mucous.

The cure is to be attempted with light, nourishing, dry aliment, not fat, but seasoned, and taken often: With a little sound drink, such as beer, not stale, but well boiled and fine: With a dry warm air, and dry warm woolen cloathing: With being carried about in the arms, and often shook, swung, and put in motion: With being drawn in a vehicle over the stones: With repeated frictions with warm dry flannel, sprinkled with aromatics; especially the abdomen and spine of the back: With prudently repeated blisters, with strengthening purges, for several days successively: As also by the continued use of strengthening, drying, antiscorbutic remedies, and such as raise the spirits.

Particularly for food, the bread should be biscuit, with a little saffron and spices. The flesh should be pigeons, pullets, veal, rabbits, mutton, gently roasted, minced, and mixed with biscuit, salt, a little parsley, thyme, nutmeg, or the like.

Likewise rice, millet, pearl-barley, boiled with raisins; to which add a little wine and spice. The drink may be generous French red wine, of which give an ounce three or four times a-day.

M E D

MEDICINES, whatever substances serve to restore health.

Medicines are either simple or compound: the former being formed by nature alone; and the latter owing to the industry of men, by variously mixing the simple ones together.

Medicines are likewise distinguished, from the manner of using them, into internal or external; and with regard to their effects, they are said to be astringent, cathartic, emetic, &c.

M E D

POCKET-MEDICINES, in surgery, those which a surgeon ought to carry always about him, in a box or convenient case.

Those, according to Heister, are the common digestive ointment, and the brown or Egyptian ointment, for cleansing and digesting foul ulcers, and some vulnerary balsams, as the linimentum arcei, or the balsam of Peru, of Gilead or Capivi, or the Samaritan balsam: to these must also be added a plaster or two, as the

diachylon, or stypticum Crollii, since one or other of these is almost constantly wanted. Neither should there be wanting a piece of blue vitriol for the taking down luxuriant flesh, and to stop hæmorrhages; but if vitriol is wanting, burnt alum, red precipitate, the infernal stone, or any other corrosive medicine, will supply its place in corrosive intentions, and the last will also serve to open abscesses, to make issues, and perform many other operations of that kind.

With these there should always be kept in readiness also a quantity of scraped lint, that the surgeon may be able to give immediate assistance to wounded persons; since if he is unprepared for this, they may easily be taken off by an hæmorrhage; a circumstance which ought also to prevail with him to be always provided with suitable bandages.

MED NA, a city of Arabia Deserta, situated two hundred miles north-west of Mecca: in E. long. $40^{\circ} 35'$. N lat. $24^{\circ} 30'$.

This is called the city of the prophet, on account of Mahomet's being received and protected by the inhabitants on his flight hither from Mecca, where the Mahometan æra commences.

MEDITERRANEAN SEA, extends from the straits of Gibraltar to the coasts of Syria and Palestine, being upwards of 2000 miles in length, but of a very unequal breadth: the west-part of it separates Europe from Africa; and the Levant or east-part of it divides Asia from Africa.

MEDITULLUM, is used by anatomists for that spongy substance between the two plates of the cranium, and in the interstices of all laminated bones.

MEDIUM, in logic, the mean or middle-term of a syllogism, being an argument, reason, or consideration for which we affirm or deny any thing: or, it is the cause why the greater extreme is affirmed or denied of the less in the conclusion.

MEDIUM, in arithmetic, or *arithmetical MEDIUM*, or *MEAN*, that which is equally distant from each extreme, or which exceeds the lesser extreme as much as it is exceeded by the greater, in respect of quantity not of proportion: thus 9 is a medium between 6 and 12.

MEDIUM, in philosophy, that space or region through which a body in motion passes to any point: thus air, is the medium wherein bodies move near our earth; water, the medium wherein fishes live and move; and glass is also a medium of light, as it affords it a free passage. That density or confidence in the parts of the medium, whereby the motion of bodies in it is retarded, is called the resistance of the medium; which together with the force of gravity, is the cause of the cessation of the motion of projectiles.

Subtile or *ætherial MEDIUM*. See *ÆTHER*.

MEDLAR, in botany. See *MESPILUS*.

MEDULLA, in anatomy. See *ANATOMY*, p. 147.

MEDULLA OBLONGATA. See *ANATOMY*, p. 287.

MEDULLA SPINALIS. See *ANATOMY*, p. 288.

MEDUSA, in zoology, a genus of insects belonging to the order of mola'ca. The body is gelatinous, roundish, and depressed; and the mouth is in the centre of the

under part of the body. There are twelve species, all natives of the sea.

MEDWAY, a river which rises in Ashdon forest in Suffex; and running through Kent, is divided into two branches by the Isle of Sheppy, one of which is called East Swale, and the other West Swale.

MEISSEN, once the capital of the marquise of Missen or Milnia, in Upper Saxony, on the river Elbe, ten miles north of Dresden.

MELAMPODIUM, in botany, a genus of the syngenesia polygamia necessaria class. The receptacle is paleaceous and conical; the pappus consists of one valve-shaped leaf, and the calyx of five leaves. There are two species, both natives of Britain.

MELAMPYRUM, a genus of the didynamia angiospermia class. The calyx has four segments; the upper lip of the corolla is compressed, and bent back at the edge; and the capsule has two oblique cells, containing two gibbous seeds. There are five species, four of them natives of Britain, *viz.* the cristatum, or crested cow-wheat; the arvense, or purple cow wheat; the pratense, or meadow cow-wheat; and the sylvaticum, or yellow cow-wheat.

MELANCHOLY, in medicine, a kind of delirium, attended with gloomy thoughts, heaviness, and sorrow. See *MEDICINE*.

MELANTERIA, in natural history, a very beautiful fossil of a dense, compact, and regular texture, and of an extremely bright pale yellow, resembling nothing so much as the purest gold: it is remarkably heavy, and is usually found in little irregular masses of the bigness of a pigeon's egg, which are broken with a slight blow; but it is usually met with in the form of a fine gold-coloured effluence or vitriolic and pyritical bodies; or in loose, shattery and friable masses of a more dusky yellow, in which latter state it so much resembles a native sulphur, that it is frequently mistaken for one; however, it is not inflammable; but calcines in the fire to a greyish powder, which by burning longer changes to a deep and fine purple.

The Greeks used it externally, as a gentle escharotic and a styptic: they made it an ingredient in their ointments for old ulcers, and used to sprinkle the powder of it on fresh wounds to stop the hæmorrhage.

MELANTHIUM, in botany, a genus of the hexandria trigynia class. The corolla consists of six petals; and the filaments are composed of the long unguis of the corolla. There are three species, none of them natives of Britain.

MELANURUS, in ichthyology. See *SPARUS*.

MELASTOMA, in botany, a genus of the decandria monogynia class. The calyx is bell-shaped, and has four segments; the petals are five, inserted into the calyx; and the berry has five cells. There are twelve species, none of them natives of Britain.

MELCHITES, in church-history, the name given to the Syriac, Egyptian, and other Christians of the Levant. The Melchites, excepting some few points of little or no importance, which relate only to ceremonies and ecclesiastical discipline, are in every respect professed

professed Greeks; but they are governed by a particular patriarch, who resides at Damas, and assumes the title of patriarch of Antioch.

MELCHISEDECHIANS, in church-history, a sect which arose about the beginning of the third century, and affirmed, that Melchisedek was not a man, but a heavenly power, superior to Jesus Christ: for Melchisedek, they said, was the intercessor and mediator of the angels; but Jesus Christ was so only for men, and his priesthood only a copy of that of Melchisedek.

MELCOMB REGIS, a borough-town of Dorsetshire, six miles south of Dorchester. It sends two members to parliament.

MELEAGRIS, the **TURKEY**, in ornithology. The head is covered with spongy caruncles; and there is likewise a membranaceous longitudinal caruncle on the throat. There are three species, *viz.* 1. The gallopavo, or North American turkey of Ray, has a caruncle both on the head and throat; and the breast of the male is bearded. He lives upon grain and insects. When the cock struts, he blows up his breast, spreads and erects his feathers, relaxes the caruncle on the forehead, and the naked parts of the face and neck become intensely red. 2. The cristata, or Brasilian pheasant of Ray, has an erect crest of feathers on the head, and violet-coloured temples; it has a caruncle on the throat, but none on the head. 3. The satyra, or horned pheasant of Edwards, has two blue horns behind the eyes, a red body spotted with black and white. It is a native of Bengal.

MFLS, in zoology. See **URUS**.

MELIA, the **BEAD TREE**, in botany, a genus of the decandria monogynia class. The calix consists of 5 teeth, and the corolla of 5 petals; the nectarium is cylindrical, about the length of the corolla, and has ten teeth on the margin; and the drupa, which is shaped like an egg, has five cells. There are two species, none of them natives of Britain.

MELIANTHUS, in botany, a genus of the didymia angiospermia class. The calix consists of five leaves; and the corolla of four petals, with a nectarium within the lowest one; and the capsule has four cells. There are two species, both natives of Ethiopia.

MELICA, in botany, a genus of the triandria digynia class. The calix consists of two valves, containing two flowers. There are three species, only one of which, *viz.* the nutans, or melic-grass, is a native of Britain.

MELICERES, in surgery, a kind of encysted tumours, so called when their contents are of the consistence of honey.

MELLILOT See **TRIFOLIUM**.

MELINDA, the capital of the province of the same name, and of all the Portuguese settlements on the coast of Malabar, in Africa: E. long. 39°, S. lat. 3°.

MELINUM, in natural history, the name of an earth, famous in the earliest ages of painting, being the only white of the great painters of antiquity; and, according to Pliny's account, one of the three colours with which alone they performed all their works. It is a fine, white, marly earth, of a very compact texture yet remarkably light; a sort of texture which must render any earth fit for the painter's use that is of a proper colour. It is frequently found forming a stratum in

the earth, lying immediately under the vegetable mould. It is of a very smooth, but not glossy surface, is very soft to the touch, adheres firmly to the tongue, is easily broken between the fingers, and stains the skin in handling. It melts readily in the mouth, and is perfectly fine, leaving not the least grittiness between the teeth. Thrown into water, it makes a great bubbling and loud hissing noise, and moulders away into a fine powder. It does not ferment with acids, and suffers no change in the fire. These are the characters by which the melinum of the ancients is distinguished from all the other white earths. It is still found in the same place from whence the painters of old had it; which is that from whence it has its name, the island of Milo, called Milos by the Greeks, and is common in most of the adjacent islands. It has been of late tried here as a paint, and is found not to make so bright a white as the other substances now in use among the painters; but seems not liable, like them, to turn yellow; and if so, would be worth the consideration of persons in the colour-trade, especially as it may be had in any quantities for carriage.

MELISSA, in botany, a genus of the didymia gymnospermia class. The calix is dry, and plain above; the upper lip of the corolla is vaulted and bifid; and the middle lobe of the under lip is cordated. There are eight species, two of which are natives of Britain, *viz.* the calaminta, or common calamint; and the repeta, or field calamint.

MELITENSIS TERRA, *earth of Malta*, an earth of which there are two very different kinds; the one of the genus of the boles, the other of the marles. The latter is that known by medicinal authors under this name; the former is the Malta earth now in use; but both being brought from the same place, are confusedly called by the same name. The Maltese marle, which is the terra Melitensis of medicinal authors, is a loose, crumbly, and very light earth, of an unequal and irregular texture, and, when exposed to the weather, soon falls into fine soft powder; but when preserved and dried, it becomes a loose, light mass, of a dirty white colour, with a greyish cast: it is rough to the touch, adheres firmly to the tongue, is very easily crumbled to powder between the fingers, and stains the hands. Thrown into water, it swells, and afterwards moulders away into a fine powder. It ferments very violently with acid menstruums.

Both kinds are found in great abundance in the island of Malta, and the latter has been much esteemed as a remedy against the bites of venomous animals, but with how much justice we cannot say. The other has supplied its place in the German shops, and is used there as a cordial, a sudorific, and astringent. See **BOLE**. **MELITIS**, in botany, a genus of the didymia gymnospermia class. The calix is larger than the tube of the corolla; the upper lip of the corolla is plain; the under lip is crenated; and the antheræ are in the form of a crows. There is but one species, *viz.* the melissophyllum, or bastard balm.

MELLER, a large lake of Sweden, on the north side of which stands the capital city of Stockholm: it is eighty miles long and thirty broad.

MELOCHIA, a genus of the monadelphia pentandria class.

- clafs. It has five ftyls; and the capſule has five cells, each containing one feed. There are fix ſpecies, none of them natives of Britain.
- MELODY**, in muſick, the agreeable effect of different ſounds, ranged and diſpoſed in ſucceſſion; ſo that melody is the effect of a ſingle voice or inſtrument, by which it is diſtinguiſhed from harmony.
- MELOE**, in zoology, agenus of inſects of the order of coleoptera. The antennæ are jointed, the laſt joint being oval; the breaſt is roundiſh; the elytra are ſoft and flexible; and the head is inſected and gibbous. There are 16 ſpecies, principally diſtinguiſhed by their colour. The veficatorius, or cantharis of the ſhops, when bruifed, is univerſally uſed as a bliſtering plaſter.
- MELON**, in botany. See **CUCUMIS**.
- MELOTHRIA**, in botany, a genus of the triandria monogynia clafs. The calix conſiſts of five ſegments; the corolla is monopetalous and bell-shaped; and the berry has one cell, containing many feeds.
- In Canada, Virginia, and Jamaica, where this fruit commonly grows, it is pickled for the table.
- MELTING-CONE**, in affaying. See **CHEMISTRY**, p. 113.
- MEMBER**, in architecture, denotes any part of a building; as, a frieze, cornich, or the like. This word is alſo ſometimes uſed for the moulding.
- MEMBER OF PARLIAMENT**. See **PARLIAMENT**.
- MEMBERED**, in heraldry, is where the legs or feet of an eagle, griffin, or other bird, are of a different colour from the reſt of the body.
- MEMBRANE**, in anatomy, a pliable texture of fibres interwoven together in the ſame plane. See **ANAT.** part I and II.
- MEMECYLON**, in botany, a genus of the octandria monogynia clafs. The calix is above the fruit, and has an entire margin; the corolla conſiſts of one petal; and the berry is crowned with a cylindrical calix. There is but one ſpecies, a native of Ceylon.
- MEMOIRS**, in matters of literature, a ſpecies of hiſtory, written by perſons who had ſome ſhare in the tranſactions they relate; answering to what the Romans called *Commentarii*.
- MEMORY**, a faculty of the human mind, whereby it retains and recalls the ideas it has once perceived. See **METAPHYSICS**.
- MEMPHIS**, once the capital of Egypt, ſtood on the weſt ſide of the Nile, almoſt oppoſite to Grand Cairo.
- MENDICANTS**, or begging friers, ſeveral orders of religious in Popiſh countries, who, having no ſettled revenues, are ſupported by the charitable contributions they receive from others.
- MENGRELIA**, a province of Aſiatic Turkey, ſituated on the north-eaſt part of the Euxine ſea, between Georgia and Circaſſia. where the Turks purchaſe boys and young women for their ſeraglios.
- MENTALS**, domeſtic or houſehold ſervants, who live under their lord or maſter's roof.
- MENINGES**, or **MENYNGES**, in anatomy, a name given to the dura and pia mater of the brain.
- MENISCUS**, in optics, a lens convex on one ſide, and concave on the other. See **OPTICS**.
- MENISPEMUM**, in botany, a genus of the dioecia decandria clafs. The calix conſiſts of fix leaves, and the corolla of fix petals. It has three berries, containing each a kidney-shaped ſeed. There are ſeven ſpecies, none of them natives of Britain.
- MENNONITES**, a ſect of baptiſts in Holland, ſo called from Mennon Simonis of Frieſland, who lived in the ſixteenth century. This ſect believe, that the New Teſtament is the only rule of faith; that the terms Perſon and Trinity are not to be uſed in ſpeaking of the Father, Son, and Holy Ghoſt; that the firſt man was not created perfect; that it is unlawful to ſwear, or to wage war upon any occaſion; that infants are not the proper ſubjects of baptiſm; and that miniſters of the goſpel ought to receive no ſalary.
- MENOLOGY**, the Greek calendar, in which the lives of the ſaints in ſhort, or barely their names, are cited; anſwering nearly to the martyrology of the Latin church. See **MARTYROLOGY**.
- MENSA**, in law-books, a term that includes in it all patrimony, and neceſſaries for livelihood.
- MENSALS**, in church-hiſtory, ſuch livings as were formerly united to the tables of religious houſes, and hence called menſal benefices.
- MENSES, FLOURS, COURSES, Catamenia**, in medicine, the monthly evacuations from the uterus of women not with child and not giving ſuck. See **MEDICINE**.
- MENSTRUUM**, in chemiſtry, any body which in a fluid or ſubtilized ſtate is capable of interpoling its ſmall parts betwixt the ſmall parts of other bodies, ſo as to divide them ſubtly, and form a new uniform compound of the two. See **CHEMISTRY**.
- MENSURATION**, in general, denotes the art or art of meaſuring lines, ſurfaces, or ſolids. See **GEO-METRY**.
- MENTHA**, in botany, a genus of the didynamia gynodioecia clafs. The corolla conſiſts of four ſegments; and the ſtamina are erect and diſtant. There are 14 ſpecies, 11 of them natives of Britain, *viz.* the ſpicata, or ſpear-mint; the longifolia, or horſe-mint; the rotundifolia, or round leaved horſe-mint; the piperita, or pepper mint; the gentilis, or red-mint; the verticillata, or curled-mint; the arvenſis, or corn-mint; the exigua, or ſmooth-mint; the aquatica, or water-mint; the hirtuta, or round-headed mint; and the pulegium, or penny-royal.
- MENTZ**, the capital of one of the elektorates of the ſame name in Germany, ſituated at the confluence of the rivers Rhine and Maine: E. long. 8°, and N. lat. 50°.
- MENYANTHES**, in botany, a genus of the pentandria monogynia clafs. The corolla is hairy; the ſtigma is biſid; and the capſule has but one cell. There are three ſpecies, two of which are natives of Britain, *viz.* the trifolia, or buck-bean; and the nymphoides, or fringed water lilly.
- MEOTIS, or PALUS MEOTIS**, a ſea of Turkey, which divides Europe from Aſia, extending from Crim Tartary to the mouth of the river Don, or Tanais.
- MERCATOR'S SAILING**, that performed by Mercator's chart. See **NAVIGATION**.

Fig. 1. MANTILE

*Fig. 3. MELEAGRIS
or Horned pheasant*

Fig. 2. MARTLETS

*Fig. 4. MERGUS or
ROUND CRESTED DUCK*

MERCHANT, a person who buys and sells commodities in gross, or deals in exchanges; or that transacts in the way of commerce, either by importation or exportation. See **COMMERCE**.

MERCURIAL, something consisting of or relating to mercury.

MERCURIALIS, in botany, a genus of the dioecia emmrandia class. The calix of both male and female consists of three segments; neither of them have any corolla; the stamina are from nine to twelve; the anthers are globular and didymous; the female has two styli; and the capsule has two cells, and one seed in each. There are four species, two of them natives of Britain, *viz.* the perennis, or dogs mercury; and the annua, or French mercury.

MERCURY, in natural history. See **CHEMISTRY**, p. 85. and 137.

MERCURY, ♀. in astronomy. See **ASTRONOMY**, p. 436.

MERCURY, in heraldry, a term used, in blazoning by planets, for the purple colour in the arms of sovereign princes.

MERCY-SEAT, in Jewish antiquity. See **PROPHETARY**.

MERGUS, in ornithology, a genus of birds, of the order of the anseres, distinguished by having the beak of a cylindrical figure, and hooked at the extremity, and its denticulations of a subulated form. There are six species of this genus, *viz.* 1. The cucullatus, or crested diver of Catfby, has a globular crest, white on each side; and the body is brown above, and white below. It is a native of America. See *Pl.* 110. 2. The merganser, has a longitudinal crest, somewhat erect, a white breast, and a black head. It is a native of Europe. 3. The ferrator, has a hanging crest, a variegated brownish breast, and a white collar. It is a bird of Europe. 4. The cafer has a crested ash coloured head, a white throat, and a black bill and legs. It inhabits the south of Europe. 5. The albellus, has a hanging crest, a black head and back, and white below. It is a bird of Europe. 6. The minutus, has a smooth gray head, with a black spot near the eyes. It is a native of Europe.

MERIDIAN. See **GEOGRAPHY**, and **ASTRONOMY**.

MERIONETHSHIRE, a county of north Wales, bounded by Caernarvon and Denbighshire on the north, by Montgomeryshire on the south east, and by the Irish sea on the west.

MERIT, signifies desert. This term is more particularly used to signify the moral goodness of the actions of men, and the rewards to which those actions intitle them.

MERLIN, in ornithology. See **FALCO**.

MERLON, in fortification, is that part of a parapet which is terminated by two embrasures of a battery.

MERNS, a county of Scotland, bounded by Mar on the north, by the German ocean on the east, by Angus on the south, and by Gowry on the west.

MEROPS, in ornithology, a genus belonging to the order of picæ. The bill is crooked, flat, and carinated; the tongue is jagged at the point; and the feet are of the walking kind. There six species, *viz.* 1. The a-

piaster, or bee-eater, has an iron-coloured back; the belly and tail are of a bluish green; and the throat is yellow. It inhabits the south of Europe. 2. The viridis, or Indian bee-eater, is green, with a black belt on the breast; and the throat and tail are black. 3. The congener is yellowish, with a green rump. It inhabits the south of Europe. 4. The superciliosus, is green, with a white line both above and below the eyes, and a yellow throat. It is found in Madagascar. 5. The cinereus, is variegated with red and yellow, with the two longest quill-feathers of the tail red. It is a native of America. 6. The cafer is grey, with a very long tail. It is a native of Æthiopia.

MERSE, a county of Scotland, bounded by Lothian on the north, by the German ocean on the east, by Northumberland and Tiviotdale on the south, and by Tweeddale on the west.

MERULA, in ornithology. See **TURDUS**.

MESEEN, the capital of a province of the same name, in Russia: it is a port-town, situated on the coast of the White sea, on hundred and fifty miles north east of Archangel.

MESEMBRYANTHEMUM, in botany, a genus of the icofandria pentagynia class. The calix consists of five segments, and the corolla of numerous linear petals; and the capsule is fleshy below the flower, and contains many seeds. There are 45 species, none of them natives of Britain.

MESENTERY, in anatomy. See **ANATOMY**, p. 262.

MESNE, in law, signifies him who is lord of a manor, and who hath tenants holding of him, yet himself holding of a superior lord.

MESOCOLON, in anatomy. See **ANATOMY**, p. 262.

MESOLOGARITHMS, according to Kepler, are the logarithms of the co-sines and co-tangents, the former of which were called by lord Napier antilogarithms, and the latter differentials.

MESOPOTAMIA, the ancient name of Diarbeck. See **DIARBECK**.

MESOPTERYGIUS, in ichthyology, a term applied to such fishes as have only one back-fin, and that situated in the middle of the back.

MESPIBUS, in botany, a genus of the icofandria pentagynia class. The calix consists of five segments, and the corolla of five petals; the berry is below the flower, and contains five seeds. There are seven species, only one of which, *viz.* the germanica, or medlar, is a native of Britain.

MESSASIPPI, or **MESCHASIPPI**, a country of North America, bounded by Canada on the north, the British plantations on the east, the gulph of Mexico on the south, and the province of New Mexico on the west.

MESENTERS, are certain officers chiefly employed under the direction of the secretaries of state, and always in readiness to be sent with all kinds of dispatches foreign and domestic. They also by virtue of the secretaries warrants, take up persons for high treason, or other offences against the state.

MESSIAH, the **ANointed**; a title which the Jews gave to their expected great deliverer, whose coming they still wait for: and a name the Christians apply to Je-

sus Christ, in whom the prophecies relating to the Messiah were accomplished.

MESUA, in botany, a genus of the polyandria monogynia class. The calix has four leaves; the corolla four petals; and the capsule has four valves, containing four seeds. There is but one species, a native of India.

METACARPUS, in anatomy. See ANATOMY, p. 181.

METALS, in natural history, are defined to be fossile bodies, fusible by fire, concreting again in the cold, and malleable, or diffensible and ductile under the hammer. See CHEMISTRY.

Semi METALS, metallic fossils, fusible by fire, and not malleable in their purest state. See CHEMISTRY.

METAL, in heraldry. There are two metals used in heraldry, by way of colours, viz. gold and silver, in blazon called *or* and *argent*.

In the common painting of arms these metals are represented by white and yellow, which are the natural colours of those metals. In engraving, gold is expressed by dotting the coat, &c. all over; and silver, by leaving it quite blank.

It is a general rule in heraldry, never to place metal upon metal, nor colour upon colour; so that if the field be of one of the metals, the bearing must be of

some colour; and if the field be of any colour, the bearing must be of one of the metals.

METALLURGY, comprehends the whole art of preparing and working metals, from the glebe, or ore, to the utensil; in which sense, assaying, smelting, refining, smythery, gilding, &c. are only branches of metallurgy.

METAMORPHOSIS, in general, denotes the changing of something into a different form; in which sense it includes the transformation of insects. See NATURAL HISTORY.

METAPHOR, in rhetoric, a trope, by which we put a strange word for a proper word, by reason of its resemblance to it; or it may be defined, a simile or comparison intended to enforce and illustrate the thing we speak of, without the signs or forms of comparison. Thus, if we say, *God is a shield to good men*, it is a metaphor: because the sign of comparison is not expressed, though the resemblance which is the foundation of the trope, is plain; for as a shield guards him that bears it, against the attacks of an enemy, so the providence and favour of God protects good men from malice and misfortunes: but if the sentence be put thus, *God is as a shield to good men*, then it becomes a simile or comparison.

M E T A P H Y S I C S.

METAPHYSICS is that part of philosophy which considers the nature and properties of thinking beings.

Aristotle, after treating on physics, begins his next book, (in which he pretends to elevate the mind above corporeal objects, to fix it on the contemplation of God, of angels, and of things spiritual, and to enable it to judge of the principles of sciences by abstraction,) with the Greek words *μετα τα φυσικα*, *post physicam*, i. e. *after metaphysics*. His disciples, and succeeding philosophers, have formed, of these two, one word, METAPHYSICS, by which they mean that science of which we have just now given the definition.

Metaphysics is divided, according to the objects that it considers, into six principal parts, which are called, 1. Ontology: 2. Cosmology: 3. Anthropology: 4. Psychology: 5. Pneumatology: and, 6. Theodicy, or metaphysical theology.

1. The doctrine that is named *Ontology*, is that part of metaphysics which investigates, and explains, the nature and general essence of all beings, as well as the qualities and attributes that essentially appertain to them, and which we ought to assign them by abstraction, as considering them *a priori*. Hence it appears, that this doctrine should proceed in its operations from the most simple ideas; such as do not admit of any other qualities of which they may be compounded. These simple ideas are, for example, those of being, of essence, of substance, of mode, of existence as well with regard to time as place,

of a necessary cause, of unity, the idea of negation, the difference between a being that is simple or compound, necessary or accidental, finite or infinite; the idea of essential and abstract properties, as of the greatness, perfection, and goodness of beings; and so of the rest. The business therefore of ontology, is to make us acquainted with every kind of being in its essence and abstract qualities, and such as are distinct from all other beings. This knowledge being once established on simple principles, just consequences may from thence be drawn, and those things proved after which metaphysics inquires, and which is its business to prove.

It is easy to conceive, that even a clear knowledge of beings, and their essential properties, would be still defective and useless to man, if he did not know how to determine and fix his ideas by proper denominations, and consequently to communicate his perceptions to those whom he would instruct, or against whom he is obliged to dispute, as they would not have the same perceptions that he has. It is, by the way, perhaps one of the greatest advantages that we have over other animals, to be able so to determine our ideas by signs or denominations, either of writing or speech, as to refer each particular perception to its general idea, and each general perception to its particular idea. To render therefore our ideas intelligible to others, we must have determinate words or denominations for each being, and the qualities of each being; and ontology teaches us those terms which are so necessary to fix our ideas, and to give them the requisite

requisite perspicuity and precision, that we may not dispute about words when we endeavour to extend the sphere of our knowledge, or when we debate concerning the essence of an object, or endeavour to make it more evident. It is for this reason that ontology was formerly regarded as a barren science, that consisted of technical terms only; as a mere terminology: whereas the best modern philosophers make it a more substantial science, by annexing determinate ideas to those words, and the examination of those objects themselves that these terms imply. But the misfortune is, to speak the truth, that in this ontologic determination there is still much uncertainty and sophistry. For, in the first place, we yet know of no metaphysics where all the definitions are just; and in the second place, the words that are employed in these definitions have always something equivocal in their meaning, and have consequently themselves need of definitions; and in this manner we may recede to infinity, unless we recur to the first impressions that the simple words have made in our minds, and the primitive ideas which they there excite. The words *man, love, coach*, &c. say more, and make a stronger impression, than all the definitions we can give of them; by ontologic explications they are almost always covered with a dark cloud.

2 Metaphysics, after having, in as solid a manner as possible, explained and established the principles above mentioned, continues its inquiries to the second part, that is called *Cosmology*, and examines into the essence of the world, and all that it contains; its eternal laws; of the nature of matter; of motion; of the nature of tangible bodies, of their attributes and essential qualities, and of all that can be known by abstraction, and sometimes also by adding the lights that man acquires concerning them by the experience of his senses. It is also in cosmology that we examine the Leibnitzian system; that is, whether God, in creating the world, must necessarily have created the best world; and if this world be so in effect. And in this manner they pursue the argument from consequence to consequence to its last resort. All philosophers, however, do not go equally deep. Each mind has its dose of penetration. Due care should be likewise taken, that subtilty, in this chain of reasoning, carried beyond the general bounds of the human mind, do not prejudge either the perspicuity or the truth of ideas: seeing that error here too nearly approaches the truth; and that every idea which cannot be rendered intelligible, is in effect equal to a false idea.

3. *Anthropology*, or the knowledge of man, forms the third branch of metaphysics. It is subdivided into two parts. The first, which consists in the knowledge of the exterior parts of the human frame, does not belong to this science: anatomy and physiology teach that. The business here is only a metaphysical examination of man, his existence, his essence, his essential qualities and necessary attributes, all considered *a priori*: and this examination leads at the same time to

4. *Psychology*, which is the fourth part of metaphysics, and consists in the knowledge of the soul in general, and of the soul of man in particular; concerning which the most profound, the most subtle and abstract researches have been made, that the human reason is capable of pro-

ducing; and concerning the substance of which, in spite of all these efforts, it is yet extremely difficult to assert any thing that is rational, and still less any thing that is positive and well supported.

5. The fifth part of metaphysics is called *Pneumatology*. It is not a very long time since this term has been invented, and that metaphysicians have made of it a distinct doctrine. By this they mean the knowledge of all spirits, angels, &c. It is easy to conceive that infinite art is necessary to give an account of what we do not absolutely know any thing, and of which, by the nature of the subject itself, we never can know any thing. But the metaphysician presently offers to show us, "what is the idea of a spirit; the effective existence of a spirit; what are its general qualities and properties; that there are rational spirits, and that these rational spirits have qualities that are founded in the moral qualities of God:" for this is, in so many words, what is taught us by pneumatology or pneumatics.

6. *Metaphysical Theology*, which M. Leibnitz and some others call *Theodicy*, is the sixth and last doctrine of metaphysics. It teaches us the knowledge of the existence of God; to make the most rational suppositions concerning his divine essence, and to form a just idea of his qualities and perfections, and to demonstrate them by abstract reasoning *a priori*. Theodicy differs from natural theology, in as much as this last borrows, in fact, from theodicy, proofs and demonstrations to confirm the existence of a Supreme Being; but after having solidly established that great truth, by extending its consequences, natural theology teaches us what are the relations and connexions that subsist between that Supreme Being and man, and what are the moral duties that result from that connexion. As pneumatology is a science highly insidious and chimerical, so is metaphysical theology susceptible of sound argument and demonstration; to the great comfort of mankind, the whole of whose happiness is founded on the certainty of this science. If the effects and operations of spirits in the universe were as evident as the effects and operations of the Deity, and their necessary existence as capable of being proved *a priori*, pneumatology would be a doctrine of equal certainty with theodicy: but as neither one nor the other can be proved, with regard to spirits in general, whilst God manifests himself in every part of nature, we have only to descend from the most simple and abstract ideas, to those that are the most compound: and from thence to ascend, by a chain of reasonings, from the creature up to the Author of the creature and of all nature: We shall find, that the result of all these operations of the mind will constantly be, The necessity of the existence of a God; and we may at all times determine, though very imperfectly, from the weakness of our discernment, what that Supreme Being must be, by positively determining what he cannot be. Every thing that can concur to furnish new proofs on this subject, or to elucidate and establish those which are already known, is therefore of inestimable value to mankind; and though this were the only object of metaphysics, it would highly merit the attention of those of the most refined and most exalted genius.

AFTER giving this general view of the subject, we shall proceed

proceed to give the substance of what Mr Locke has delivered upon it.

Of ideas in general, and their original.

By the term *idea*, as defined by Mr Locke, is meant whatever is the object of the understanding when a man thinks, or whatever it is which the mind can be employed about in thinking.

In order to trace the manner by which we acquire these ideas, let us suppose the mind to be, as we say, *white paper*, void of all characters, without any *ideas*: how comes it to be furnished? whence has it all the materials of reason and knowledge? From *experience* and *observation*. This, when employed about external sensible objects, we may call *sensation*: by this we have the ideas of *bitter, sweet, yellow, hard, &c.* which are commonly called *sensible qualities*, because conveyed into the mind by the senses. The same experience, when employed about the internal operations of the mind, perceived and reflected on by us, we may call *reflection*: hence we have the *ideas* of *perception, thinking, doubting, willing, reasoning, &c.*

These two, viz. *external material things* as the objects of sensation, and *the operations of our own minds* as the objects of reflection, are the only *originals* from whence all our *ideas* take their beginnings: the understanding seems not to have the least glimmering of *ideas*, which it does not receive from one of these two *sources*. These, when we have taken a full survey of them, and their several *modes* and *compositions*, we shall find to contain our whole stock of *ideas*; and that we have nothing in our minds which did not come in one of these two ways.

It is evident, that children come by degrees to be furnished with *ideas* from the objects they are conversant with: they are so surrounded with bodies that perpetually and diversely affect them, that some ideas will (whether they will or no) be imprinted on their minds. *Light* and *colours, sounds* and *tangible qualities*, do continually sollicit their proper senses, and force an entrance into the mind. It is late, commonly, before *children* come to have *ideas* of the operations of their minds; and some men have not any very clear or perfect *ideas* of the greatest part of them all their lives: because, though they pass there continually, yet, like floating visions, they make not deep impressions enough to leave in the mind clear and lasting *ideas*, till the understanding turns inward upon itself, and reflects on its own operation, and makes them the objects of its own contemplation.

When a man *first perceives*, then he may be said to have *ideas*; having *ideas*, and perception, signifying the same thing.

Of simple ideas.

Or *ideas*, some are *simple*, others *complex*. A *simple idea* is one uniform appearance or conception in the mind, which is not distinguishable into different *ideas*. Such are the *ideas* of *sensible qualities*, which though they are in the things themselves so united and blended, that there is no separation, no distance between them, yet the *ideas* they produce in the mind enter by the senses simple and unmixed. Thus, though the hand feels

softness and *warmth* in the same piece of *wax*, yet the *simple ideas* thus united in the same subject are as perfectly distinct as those that come in by different senses.

These *simple ideas* are suggested no other way than from the two ways above mentioned, viz. *sensation* and *reflection*.

The mind being once stored with the *simple ideas*, has the power to repeat, compare, and unite them to an infinite variety; and so can make, at pleasure, new *complex ideas*. But the most enlarged understanding cannot frame one new *simple idea*; nor by any force destroy them that are there.

Of ideas of one sense.

IDEAS, with reference to the different ways wherein they approach the mind, are of *four sorts*.

First, There are some which come into our minds by *one sense* only.

Secondly, There are others conveyed into the mind by *more senses* than one.

Thirdly, Others that are had from *reflection* only.

Fourthly, There are some suggested to the mind by all the ways of *sensation* and *reflection*.

First, some enter into the mind only by one sense peculiarly adapted to receive them. Thus colours, sounds, smells, &c. come in only by the eyes, ears, and nose. And if these organs are any of them so disordered as not to perform their functions, they have no other way to bring themselves in view, and be perceived by the understanding.

We shall here mention one, which we receive by our touch, because it is one of the chief ingredients in many of our complex ideas; and that is, the idea of *solidity*: it arises from the resistance one body makes to the entrance of another body into the place it possesses, till it has left it. There is no idea which we more constantly receive from sensation than this. In whatever posture we are, we feel somewhat that supports us, and hinders us from sinking downwards: and the bodies we daily handle, make us perceive, that while they remain between them, they do, by an unsurmountable force, hinder the approach of the parts of our hands that press them. This seems to be the most essential property of body, and that whereby we conceive it to fill space: the idea of which is, that where we imagine any space taken up by a solid substance, we conceive it so to possess it, that it excludes all other solid substances. This resistance is so great, that no force can surmount it. All the bodies in the world pressing a drop of water on all sides, will never be able to overcome the resistance it makes to their approaching one another, till it be removed out of their way.

The idea of *solidity* is distinguished from that of *pure space*, in as much as this latter is neither capable of resistance nor motion: it is distinguished from *hardness*, in as much as hardness is a firm cohesion of the solid parts of matter making up masses of a sensible bulk, so that the whole doth not easily change its figure. Indeed, *hard* and *soft*, as commonly apprehended by us, are but *relative* to the constitutions of our bodies: that being called *hard* which will put us to pain sooner than change its figure by the pressure of any part of our bodies; and that *soft*, which

which changes the situation of its parts upon an easy and unpainful touch.

This difficulty of changing situation among the parts, gives no more solidity to the hardest body, than to the softest; nor is an adamant one jot more solid than water. He that shall fill a yielding soft body well with air or water, will quickly find its resistance. By this we may distinguish the idea of the extension of body, from the idea of the extension of space: That of body, is the cohesion or continuity of solid, separable, and moveable parts; that of space, the continuity of unsolid, inseparable, and immoveable parts. Upon the solidity of bodies depends their mutual impulse, resistance, and protrusion.

Of simple ideas of different senses.

SOME ideas we get into the mind by *more than one sense*; as *space, extension, figure, rest, and motion*. These are perceivable by the eyes and touch.

Of simple ideas of reflection.

SOME ideas are had from reflection only: Such are the ideas we have of the operations of our minds; of which the two principal are, *perception, or thinking; and volition, or willing*. The powers of producing these operations are called *faculties*; which are, the *understanding, and will*. The several *modes* of thinking, &c. belong to this head.

Of simple ideas of sensation and reflection.

THERE are some simple ideas conveyed into the mind by all the ways of *sensation and reflection*; such are *pleasure, pain, power, existence, unity, succession*. Pleasure or delight, pain or uneasiness, accompany almost every impression on our senses, and every action or thought of the mind.

The Author of our beings having given a power to our minds, in several instances, to chuse amongst its ideas which it will think on; to excite us to these actions of *thinking and motion*, he has joined to several thoughts and sensations a perception of delight: without this we should have no reason to prefer one thought or action to another.

Pain has the same efficacy to set us on work that pleasure has; since we are as ready to avoid that, as to pursue this. This is worth our consideration, that *pain is often produced by the same objects and ideas that produce pleasure* in us. This their near conjunction gives us new occasion of admiring the wisdom and goodness of our Maker; who, designing the preservation of our being, has annexed pain to the application of many things to our bodies, to warn us of the harm they will do us, and as advices to withdraw us from them. But he not designing our preservation barely, but the preservation of every part and organ in its perfection, hath in many cases annexed pain to those very ideas which delight us. Thus heat, that is very agreeable to us in one degree, by a little greater increase of it proves no ordinary torment: Which is wisely ordered by nature, that when any object does by the vehemence of its operation disorder the instruments of sensation, whose structures cannot but be very delicate, we might by the pain be warn-

ed to withdraw before the organ be quite put out of order. That this is the *end of pain*, appears from this consideration; that though great light is insufferable to the eyes, yet the highest degree of *darkness* does not at all disease them; because that causes no disorderly motion in that curious organ the eye. But excess of *cold*, as well as *heat*, pains us; because it is equally destructive to the temper which is necessary to the preservation of life.

Existence and unity are two other ideas suggested by every object without, and every idea within. When ideas are in our minds, we consider them as being actually there, as well as we consider things to be actually without us; which is, that they *exist*, or have existence: And whatever we consider as *one thing*, whether a *real being, or idea*, suggests the idea of *unity*.

Power is another idea derived from these sources: For finding in ourselves that we can *think*, and *move* several parts of our bodies at pleasure, and observing the *effects* that natural bodies produce in one another; by both these ways we get the idea of *power*.

Succession is another idea suggested by our senses, and by reflection on what passes in our minds: For if we look into ourselves, we shall find our *ideas* always, whilst we are awake, or have any thought, passing in train, one going and another coming, without intermission.

Some farther considerations concerning simple ideas.

WHATsoever is able, by affecting our senses, to cause any perception in the mind, doth thereby produce in the understanding a *simple idea*; which, whatever be the cause of it, is looked upon as a *real positive idea* in the understanding. Thus the ideas of *heat and cold, light and darkness, motion and rest, &c.* are equally positive in the mind, though some of their causes may be mere *privations*.

That a *privative* cause may produce a *positive* idea, appears from shadows; which (though nothing but the absence of light) are discernible, and cause clear and positive ideas. We have indeed some *negative* names which stand not directly for positive ideas, but for their absence; such as *insipid, silence*, which denote positive ideas, *viz. taste and sound*, with a signification of their absence.

It will be useful to distinguish *ideas* as they are *perceptions* in our minds, from what they are in the bodies that cause such perceptions in us; for we are not to think the former exact images and resemblances of something inherent in the subject, most of those of *sensation* being, in the mind, no more the likeness of something existing without us, than the names that stand for them are the likeness of our ideas, which yet, upon hearing, they excite in us.

Whatsoever the mind perceives in itself, or is the immediate object of perception, thought, or understanding, is an idea: And the power to produce any idea in our mind, is the *quality of the subject* wherein that power exists. Thus a *snow ball* having the power to produce in us the ideas of *white, cold, and round*; those powers, as they are in the snow ball, are called *qualities*; and as they are *sensations or perceptions* in our understandings, they are called *ideas*. These *qualities* are of two sorts: First, *original*, or primary; such are *solidity, extension,*

tension, motion, or rest, number, and figure. These are inseparable from body, and such as it constantly keeps in all its changes and alterations.

Secondly, *Secondary qualities*; such as *colours, smells, tastes, sounds*, &c. which, whatever reality we by mistake may attribute to them, are in truth nothing in the objects themselves, but *powers* to produce various sensations in us; and depend on the qualities before mentioned.

The *ideas of primary* qualities of bodies, are resemblances of them; and their patterns really exist in bodies themselves: But the ideas produced in us by secondary qualities have no resemblance of them at all; and what is *sweet, blue, or warm*, in the idea, is but the certain bulk, figure, and motion of the insensible parts in the bodies themselves, which we call so.

Thus we see, that fire at one distance produces in us the sensation of *warmth*, which at a nearer approach causes the sensation of *pain*. Now what reason have we to say, that the idea of *warmth* is actually in the fire; but that of *pain* not in the fire; which the same fire produces in us the same way? The bulk, number, figure, and motion of the parts of fire, are really in it, whether we perceive them or no; and therefore may be called *real* qualities, because they really exist in that body: But *light* and *heat* are no more really in it, than sickness or pain: Take away the sensation of them; let not the eyes see light or colours, nor the ear hear sounds; let the palate not taste, or the nose smell; and all *colours, tastes, odours, and sounds*, as they are such particular ideas, vanish and cease, and are reduced to their causes, (that is,) bulk, motion, figure, &c. of parts.

These *secondary* qualities are of two sorts. First, *Immediately perceivable*; which by immediately operating on our bodies, produce several different ideas in us. Secondly, *Mediately perceivable*; which by operating on other bodies, change their primary qualities, so as to render them capable of producing ideas in us different from what they did before. These last are powers in bodies, which proceed from the particular constitution of those primary and original qualities, to make such a change in the *bulk, figure, texture*, &c. of another body, as to make it operate on our senses different from what it did before; as in fire, to make lead fluid. These two last being nothing but powers relating to other bodies, and resulting from the different modifications of the original qualities, are yet otherwise thought of; the former being esteemed *real qualities*, but the latter barely *powers*.

Of perception.

PERCEPTION is the first idea we receive from reflection: It is by some called *thinking* in general: Though *thinking*, in the propriety of the *English* tongue, signifies that sort of operation of the mind about its ideas, wherein the mind is active; where it considers any thing with some degree of voluntary attention: For in bare *perception* the mind is, for the most part, only *passive*; and what it perceives, it cannot avoid perceiving. What this is, we cannot otherwise know, than by reflecting on what passes in our minds when we see, feel, hear, &c.

Impressions made on the outward parts, if they are not taken notice of within, cause no *perception*; as we see in those whose minds are intently busied in the contemplation of certain objects.

We may observe that the ideas we receive from sensation, are often in grown people altered by the judgment, without our taking notice of it. Thus a globe of any uniform colour, (as of gold, or jet,) being set before our eyes, the *idea* thereby imprinted is of a flat circle variously shadowed: But being accustomed to perceive what kind of appearance convex bodies are wont to make in us, the judgment alters the appearances into their causes; and, from that variety of shadow or colour, frames to itself the perception of a convex figure of one uniform colour. This in many cases, by a settled habit, is performed so readily, that we take that for the perception of our sensation, which is but an idea formed by the judgment; so that one serves only to excite the other, and is scarce taken notice of itself: As a man who reads or hears with attention, takes little notice of the characters or sounds, but of the ideas that are excited in him by them.

Perception is also the first step and degree towards knowledge, and the inlet of all the materials of it; so that the fewer senses any man has, and the duller the impressions that are made by them are, the more remote he is from that knowledge which is to be found in other men.

Of retention.

THE next faculty of the mind whereby it makes a further progress towards knowledge, is called *retention*; which is the keeping of those ideas it has received. Which is done two ways:

First, By keeping the idea which is brought into the mind for some time actually in view; which is called *contemplation*.

Secondly, By reviving those ideas in our minds which have disappeared, and have been, as it were, laid out of sight: And this is *memory*; which is, as it were, the store-house of our ideas; for the narrow mind of man not being capable of having many ideas under view at once, it was necessary to have a repository to lay up those ideas, which at another time it may have use of. But our ideas being nothing but actual perceptions in the mind, which cease to be any thing when there is no perception of them, this lying up of our *ideas* in the repository of the memory signifies no more but this, that the mind has a power, in many cases, to revive perceptions it has once had, with this additional perception annexed to them, that it has had them them before. And it is by the assistance of this faculty, that we are said to have all those ideas in our understandings which we can bring in sight, and make the objects of our thoughts, without the help of those sensible qualities which first imprinted them there.

Those ideas that are often refreshed by a frequent return of the objects or actions that produce them, fix themselves best in the memory, and remain longest there: Such are the *original qualities of bodies*. viz. Solidity, extension, figure, motion, &c. These and the like are seldom quite lost while the mind retains any *ideas* at all.

Of discerning, and other operations of the mind.

ANOTHER faculty of the mind, is that of *discerning between its ideas*. On this depends the evidence and certainty of several general propositions. In being able nicely to distinguish one thing from another, where there is the least difference, consists, in a great measure, that *exactness of judgment and clearness of reason* which is to be observed in one man above another.

To the well distinguishing our *ideas*, it chiefly contributes that they be clear and determinate; and when they are so, it will not breed any confusion or mistake about them, though the senses should convey them from the same object differently on different occasions.

The comparing of our *ideas* one with another in respect of *extent, degree, time, place*, or any other circumstances, is another operation of the mind about its *ideas* which is the ground of *relations*. Brutes seem not to have this faculty in any great degree. They have probably several *ideas* distinct enough; but cannot compare them farther than some sensible circumstances annexed to the objects themselves.

Composition is another operation of the mind, whereby it combines several of its simple *ideas* into *complex* ones: Under which operation we may reckon that of *enlarging*; wherein we put several *ideas* together of the same kind, as several units to make a *dozen*.

Abstraction is another operation of the mind, whereby the mind forms general *ideas* from such as it received from particular objects; which it does by considering them, as they are in the mind such appearances separate from the circumstances of real existence, as *time, place*, &c. These become general *representatives* of all of the same kind, and their names applicable to whatever exists conformable to such abstract *ideas*. Thus the colour received from *chalk, snow, and milk*, is made a representative of all of that kind; and has a name given it (*whiteness*), which signifies the same quality, wherever to be found or imagined. And thus *universals*, both *ideas* and *terms*, are made.

Of complex ideas.

In the reception of simple *ideas* the mind is only *passive*, having no power to frame any one to itself, nor having any *idea* which does not wholly consist of them. But about these simple *ideas* it exerts several acts of its own, whereby out of them, as the materials and foundations of the rest, the other are framed: The acts of the mind, wherein it exerts its power over its simple *ideas*, are chiefly these three: *First*, It combines several simple *ideas* into one compound one; and thus all *complex ideas* are made. *Secondly*, It brings two *ideas*, whether *simple* or *complex*, together, and sets them by one another. So as to take a view of them at once, without uniting them into one; by which way it gets all its *ideas* of *relations*. *Thirdly*, It separates them from all other *ideas* that accompany them in their real existence: And thus all its *general ideas* are made. As *simple ideas* are observed to exist in several combinations united together, so the mind may consider them as united, not only as they are really united in external objects, but as itself has joined them *Ideas* thus made up of several ones put together, are called

complex; as *man, army, beauty, gratitude*, &c. By this faculty of repeating and joining together its *ideas*, the mind has great power in varying and multiplying the objects of its thoughts. But it is still confined to those simple *ideas* which it received from the two sources of *sensation and reflection*. It can have no other *ideas* of sensible qualities, than what come from without by the senses, nor any other *ideas* of the operations of a thinking substance than what it finds in itself; but having once got these simple *ideas*, it can by its own power put them together, and make new *complex ones*, which it never received so united.

Complex ideas, however compounded and decompounded, though their number be infinite, and their variety endless, may all be reduced under these three heads: 1st, *Modes*; 2^{dly}, *Substances*; 3^{dly}, *Relations*.

1st, *Modes* are such *complex ideas* as contain not the supposition of subsisting by themselves, but are considered as dependences on, and affections of substances; as *triangle, gratitude, murder*, &c. These *modes* are of two sorts: First, *Simple*; which are combinations of the same simple *idea*; as a *dozen, score*, &c. which are but the *ideas* of so many distinct units put together. Secondly, *Mixed*; which are compounded of simple *ideas* of several kinds; as *beauty*, which consists in a certain composition of colour and figure, causing delight in the beholder; *thief*, which is the concealed change of the possession of any thing, without the consent of the proprietor. These visibly contain a combination of *ideas* of several kinds.

2^{dly}, *Substances*. The *ideas* of substances are only such combinations of simple *ideas*, as are taken to represent distinct particular things subsisting by themselves, in which the confused *idea* of substance is always the chief. Thus a combination of the *ideas* of a certain figure, with the powers of motion, thought, and reasoning, joined to substance, make the ordinary *idea* of man.

These again are either of *single substances*, as *man, stone*; or of *collective*, or several put together, as *army, heap*. *Ideas* of several substances thus put together, are as much each of them one single *idea*, as that of a *man* or an *unit*.

3^{dly}, *Relations*; which consist in the consideration and comparing of one *idea* with another. Of these several kinds we shall treat in their order.

Of simple modes: And, first, of the simple modes of space.

CONCERNING *simple modes* we may observe, that the modifications of any *simple ideas* are as perfectly different and distinct *ideas* in the mind, as those of the greatest distance or contrariety: Thus *two* is as distinct from *three*, as *blueness* from *heat*.

Space is a simple *idea* which we get both by our sight and touch. When we consider it barely in length between two bodies it is called *distance*: when in length, breadth, and thickness, it may be called *capacity*. When considered between the extremities of matter, which fills the capacity of space with something solid, tangible, and moveable, it is called *extension*. And thus *extension* will be an *idea* belonging to body; but *space* may be conceived without it.

Each

Each different *distance* is a different modification of space; and each *idea* of any different space is a *simple mode* of this *idea*. Such are an *inch*, *foot*, *yard*, &c. When these *ideas* are made familiar to mens thoughts, they can in their minds repeat them as often as they will, without joining to them the *idea* of body, and frame to themselves the *ideas* of feet, yards, or fathoms, beyond the utmost bounds of all bodies; and, by adding these still one to another, enlarge their *idea* of space as much as they please. From this power of repeating any *idea* of distance, without being ever able to come to an end, we come by the *idea* of immensity.

Another modification of *space* is taken from the *relation* of the parts of the termination of extension or circumscribed space amongst themselves; and this is what we call *figure*. This the *touch* discovers in sensible bodies, whose extremities come within our reach; and the *eye* takes both from bodies and colours, whose boundaries are within its view; where observing how the extremities terminate either in straight lines, which meet at discernible angles, or in crooked lines, wherein no angles can be perceived; by considering these as they relate to one another in all parts of the extremities of any body or space, it has that *idea* we call *figure*: which affords to the mind infinite variety.

Another *mode* belong to this head, is that of *place*. Our *idea* of *place* is nothing but the relative position of any thing with reference to its distance from some fixed and certain points. Whence we say, that a thing has or has not changed *place*, when its distance either is or is not altered with respect to those bodies which we have occasion to compare it. That this is so, we may easily gather from hence, that we can have no *idea* of the *place* of the *universe*, though we can of all its parts. To say that the world is *somewhere*, means no more than that it does *exist*. The word *place* is sometimes take to signify that *space* which any body takes up; and so the *universe* may be conceived in a *place*.

Of duration, and its simple modes.

THERE is another sort of *distance*, the *idea* of which we get from the fleeting and perpetually perishing parts of succession, which we call *duration*. The simple modes of it are any different lengths of it whereof we have distinct *ideas*; as *hours*, *days*, *years*, &c. *time*, and *eternity*.

The *idea* of *succession* is got by reflecting on that train of *ideas* which constantly follow one another in our minds as long as we are awake. The distance between any parts of this *succession*, is what we call *duration*; and the continuation of the existence of ourselves, or any thing else, *commensurate* to the succession of any *ideas* in our minds, is what we call our *own duration*, or that of another thing co-existing with our thinking. That this is so, appears from hence, that we have no perception of succession or duration, when that succession of our *ideas* ceases, as in *sleep*: the moment that we sleep, and awake, how distant soever, seems to be joined and connected. And possibly it would be so to a waking man, could he fix upon one *idea* without variation and the succession of others. And we see that they whose thoughts are

very intent upon one thing, let slip out of their account a good part of that *duration*, and think that time shorter than it is. But if a man, during his sleep, *dream*, and a variety of *ideas* make themselves perceptible in his mind one after another, he hath then, during such dreaming, a sense of *duration*, and of the length of it.

A man having once got this *idea* of duration, can apply it to things which exist while he does not think: and thus we measure the time of our sleep, as well as that wherein we are awake.

Duration, as marked by certain periods and measures, is what we most properly call *time*; which we measure by the diurnal and annual *revolutions* of the sun, as being constant, regular, and universally observable by all mankind, and supposed equal to one another.

The mind having once got such a measure of *time*, as the annual revolution of the sun, can easily apply it to duration, wherein that measure itself did not exist; and the *idea* of *duration* equal to an annual revolution of the sun, is as easily applicable in our thoughts to duration where no sun nor motion was, as the *idea* of a *foot* or *yard* to distances beyond the confines of the world.

By the same means, and from the same original that we come to have the *idea* of time, we have also that *idea* which we call *eternity*: for having got the *ideas* of certain lengths of duration, we can in our thoughts add them to one another as oft as we please, without ever coming to an end.

And thus it is plain, that from the two fountains of all knowledge before mentioned, *viz.* *sensation* and *reflection*, we get the *ideas* of duration, and the several measures of it.

Of numbers.

THE complex *ideas* of *number* are formed by adding several units together. The simple modes of it are each several combinations, as *two*, *three*, &c. These are of all others most distinct, the nearest being as clearly different from each other as the most remote: *two* being as distinct from *one*, as two hundred. But it is hard to form distinct *ideas* of every the least excess in extension. Hence demonstrations in numbers are more general in their use, and more determinate in their application, than those of extension.

Simple modes of numbers being in our minds but so many combinations of units, which have no variety but more or less; names for each distinct combination seem more necessary than in any other sort of *ideas*: For without a name, or mark, to distinguish that precise collection, it will hardly be kept from being a heap of confusion. Hence some *Americans* have no distinct *idea* of any number beyond twenty; so that when they are discoursed with of greater numbers, they shew the hairs of their head. So that to reckon right, two things are required:

First, That the mind distinguish carefully two *ideas* which are different one from another only by the addition or subtraction of one unit.

Secondly, That it retain in memory the names or marks of the several combinations, from an unit to that number; and that in exact order, as they follow one another. In either

either of which if it fails, the whole business of *nursing* will be disturbed; and there will remain only the confused idea of *multitude*; but the *ideas* necessary to distinct numeration will not be attained to.

Of infinity.

THE *idea* signified by the name *infinity*, is best examined, by considering to *what* infinity is by the mind attributed, and then *how* it frames it. *Finite* and *infinite*, then, are looked upon as the modes of quantity; and attributed primarily to things that have parts, and are capable of increase or diminution by the *addition* or *subtraction* of any the least part. Such are the *ideas* of *space*, *duration*, and *number*.

When we apply this *idea* to the *Supreme Being*, we do it primarily, in respect of his duration and ubiquity; more figuratively, when to his *wisdom*, *power*, *goodness*, and other attributes, which are properly *inexhaustible* and *incomprehensible*: For when we call them *infinite*, we have no other *idea* of this infinity, but what carries with it some reflection on the *number* or the *extent* of the *acts* or *objects* of God's power and wisdom, which can never be supposed so great, or so many, that these attributes will not always surmount and exceed, though we multiply them in our thoughts with the infinity of *endless number*.

The next thing to be considered, is, *How we come by the idea* of infinity. Every one that has any idea of any stated lengths of space, as a *foot*, *yard*, &c. finds that he can repeat that *idea*, and join it to *another*, to a *third*, and so on without ever coming to an end of his additions. From this power of enlarging his *idea* of space, he takes the *idea* of infinite space, or *immensity*. By the same power of repeating the *idea* of any length of duration we have in our minds, with all the endless addition of number, we come by the *idea* of *eternity*.

If our *idea* of *infinity* be got by repeating without end our own *ideas*; why do we not attribute it to other *ideas*, as well as those of *space* and *duration*; since they may be as easily and as often repeated in our minds, as the other: Yet no body ever thinks of infinite *sweetness* or *whiteness*, though he can repeat the *idea* of *sweet* or *white* as frequently as those of *yard* or *day*. But those *ideas* that have parts, and are capable of increase by the addition of any parts, afford us, by their repetition, an *idea* of infinity; because with the endless repetition there is continued an enlargement, of which there is no end. But it is not so in other *ideas*: For if to the perfect *idea* I have of *white*, I add another of equal whiteness; it enlarges not my *idea* at all. Those *ideas* that consist not of parts, cannot be augmented to what proportion men please; or be stretched beyond what they have received by their senses: But *space*, *duration*, and *number*, being capable of increase by repetition, leave in the mind an *idea* of an endless room for more; and so those *ideas* alone lead the mind towards the thought of infinity.

Of the modes of thinking.

WHEN the the mind turns its view inwards upon itself, *thinking* is the first idea that occurs: Wherein it observes a great variety of modifications; and thereof frames to

itself distinct *ideas*. Thus the perception annexed to any impression on the body made by an external object, is called *sensation*. When an *idea* recurs without the presence of the object, it is called *remembrance*: When fought after by the mind, and brought again in view, it is *recollection*: When held there long under attentive consideration, it is *contemplation*. When *ideas* float in the mind without regard or reflection, it is called in French *réverie*; our language has scarce a name for it: When the *ideas* are taken notice of, and, as it were, registered in the memory, it is *attention*: When the mind fixes its view on any one *idea*, and considers it on all sides, it is *intention* and *study*. *Sleep*, without dreaming, is rest from all these. And *dreaming* is the perception of *ideas* in the mind, not suggested by any external objects, or known occasions; nor under any choice or conduct of the understanding.

Of the modes of pleasure and pain.

PLEASURE and pain are simple *ideas*, which we receive both from sensation and reflection. There are thoughts of the mind, as well as sensations, accompanied with pleasure or pain. Their causes are termed *good* or *evil*. *Pleasure* and *pain*, and their causes *good* and *evil*, are the hinges upon which our passions turn; by reflecting on the various modifications or tempers of mind, and the internal sensations which pleasure and pain, good and evil, produce in us, we may thence form to ourselves the *idea* of our passions. Thus by reflecting upon the thought we have of the delight which any thing is apt to produce in us, we have an *idea* we call *love*: And on the contrary, the thought of the pain which any thing present or absent produces in us, is what we call *hatred*. *Desire* is that uneasiness which a man finds in himself upon the absence of any thing the present enjoyment of which carries the *idea* of delight with it. *Joy* is a delight of the mind arising from the present or assured approaching possession of a good. *Sorrow* is an uneasiness of the mind, upon the thought of a good lost, or the sense of a present evil. *Hope* is a pleasure in the mind, upon the thought of a probable future enjoyment of a thing which is apt to delight. *Fear* is an uneasiness of the mind, upon the thought of a future evil likely to befall us. *Anger* is a discomposure of mind, upon the receipt of injury, with a present purpose of revenge. *Despair* is the thought of the unattainableness of any good. *Envy* is an uneasiness of mind, caused by the consideration of a good we desire, obtained by one we think should not have had it before us.

It is to be considered, that in reference to the passions, the removal or lessening of a pain, is considered and operates as a pleasure; and the loss or diminishing of a pleasure, as a pain. And farther, that the passions in most persons operate on the body, and cause various changes in it; but these being not always sensible, do not make a necessary part of the *idea* of each passion.

Of power.

THE mind being every day informed by the senses of the alteration of those simple *ideas* it observes in things without, reflecting also on what passes within itself, and

observing

observing a constant change of its *ideas*, sometimes by the impressions of outward objects upon the senses, and sometimes by the determination of its own choice; and concluding, from what it has so constantly observed to have been, that the like changes will for the future be made in the same things, by the same agents, and by the like ways, considers in one thing the possibility of having any of its simple *ideas* changed, and in another the possibility of making that change, and so comes by that *idea* which we call *power*. Thus we say *fire* has a power to melt *gold*, and make it fluid; and *gold* has a power to be melted.

Power thus considered, is twofold, *viz.* as able to make, or able to receive any change: the one may be called *active*, the other *passive power*. Of *passive power* all sensible things abundantly furnish us with *ideas*, whose sensible qualities and beings we find to be in a continual flux. Nor have we of *active power* fewer instances; since whatever change is observed, the mind must collect a power somewhere able to make that change. But yet, if we will consider it attentively, bodies by our senses do not afford us so clear and distinct an *idea* of *active power* as we have from reflection on the operations of, our minds. For all power relating to action, and there being but two sorts of action, *viz.* *thinking* and *motion*, let us consider whence we have the clearest *ideas* of the powers which produce these actions.

Of *thinking*, body affords us no *idea* at all: It is only from reflection that we have that; neither have we from body any *idea* of the beginning of motion. A body at rest, affords us no *idea* of any *active power* to move; and when it is set in motion itself, that motion is rather a passion than an action in it. The *idea* of the beginning of motion; we have only by reflection on what passes in ourselves; where we find by experience, that barely by willing it, we can move the parts of our bodies which were before at rest.

We find in ourselves a power to begin or forbear, continue or end, several actions of our minds, and motions of our bodies, barely by a thought, or preference of the mind. This power which the mind has thus to order the consideration of any *idea*, or the forbearing to consider it; or to prefer the motion of any part of the body to its rest, and *vice versa*, in any particular instance, is that we call the *will*; the actual exercise of that power is that which we call *volition*, or *willing*. The forbearance or performance of that action, consequent to such order or command of the mind, is called *voluntary*; and whatsoever action is performed without such a thought of the mind, is called *involuntary*.

The power of perception is that we call the *understanding*. Perception, which we make the act of the understanding, is of three sorts: 1st, The perception of *ideas* in our minds. 2^{dly}, The perception of the signification of signs. 3^{dly}, The perception of the agreement or disagreement of any distinct *ideas*. These powers of the mind, *viz.* of perceiving and preferring, are usually called by another name; and the ordinary way of speaking is, that the understanding and will are two *faculties* of the mind.

From the consideration of the extent of the power of

the mind over the actions of the man, which every one finds in himself, arise the *ideas* of *liberty* and *necessity*: so far as a man has a power to think or not to think, to move or not to move, according to the preference or direction of his own mind, so far is a man free. Wherever any performance or forbearance are not equally in a man's power; where ever doing, or not doing, will not equally follow upon the preference of his mind; there he is not *free*, though perhaps the action may be *voluntary*. So that the *idea* of *liberty*, is the *idea* of a power in any agent to do or forbear any action, according to the determination or thought of the mind whereby either of them is preferred to the other. Where either of them is not in the power of the agent to be produced by him, according to his volition, there he is not at liberty; that agent is under *necessity*. So that *liberty* cannot be where there is no *thought*, no *volition*, no *will*; but there may be thought, there may be will, there may be volition, where there is no *liberty*. Thus a *tennis ball*, whether in motion by the stroke of a racket, or lying still at rest, is not by any one taken to be a free agent. So a man striking himself or his friend by a convulsive motion of his arm, which it is not in his power by volition or the direction of his mind to stop or forbear; no body thinks he has in this *liberty*; every one pities him, as acting by *necessity* and *constraint*. Again, suppose a man be carried whilst fast asleep into a room, where is a person he longs to see, and be there locked fast in, beyond his power to get out; he awakes, and is glad to see himself in so desirable company; which he stays willingly in, that is, prefers his staying to going away. Is not this stay voluntary? no body will doubt it; and yet being locked fast in, he is not at liberty to stay, he has not freedom to be gone. So that *liberty* is not an *idea* belonging to volition or preferring, but to the person having the power of doing, or forbearing to do, according as the mind shall chuse or direct.

As it is in the motions of the body, so it is in the thoughts of our minds: where any one is such, that we have power to take it up, or lay it by, according to the preference of the mind, there we are at liberty. A waking man is not at liberty to think, or not to think, no more than he is at liberty whether his body shall touch any other or no: But whether he will remove his contemplation from one *idea* to another, is many times in his choice. And then he is, in respect of his *ideas*, as much at liberty, as he is in respect of bodies he rests on. He can at pleasure remove himself from one to another: but yet some *ideas* to the mind, like some motions to the body, are such, as in certain circumstances it cannot avoid, nor obtain their absence by the utmost effort it can use. Thus a man on the rack is not at liberty to lay by the *idea* of *pain*, and entertain other contemplations.

Where ever thought is wholly wanting, or the power to act or forbear according to the direction of thought, there necessity takes place. This in an agent capable of volition, when the beginning or continuation of any action is contrary to the preference of his mind, is called *compulsion*; when the hindering or stopping any action is contrary to his volition, it is called *restraint*: Agents that have no thought, no volition at all, are in every thing necessary agents.

Of mixed modes.

Mixed modes are combinations of *simple ideas* of different kinds. The mind being once furnished with *simple ideas*, can put them together in several compositions, without examining whether they exist together in nature. And hence it is, that these ideas are called *notions*, as if they had their original and constant existence more in the thoughts of men, than in the reality of things: and to form such ideas, it sufficed that the mind put the parts of them together, and that they were consistent in the understanding, without considering whether they had any real being. There are three ways whereby we get these complex ideas of *mixed modes*.

1st, By *experience*, and observation of things themselves: Thus by seeing two men wrestle, we get the *idea* of wrestling.

2dly, By *invention*, or voluntary putting together of several *simple ideas* in our own minds: So he that first invented *printing*, had an *idea* of it first in his mind before it ever existed.

3dly, By *explaining* the names of actions we never saw, or nations we cannot see; and by enumerating all those *ideas* which go to the making them up. Thus the mixed mode, which the word *lie* stands for, is made up of these *simple ideas*: 1st, *Articulate sounds*. 2dly, *Certain ideas in the mind of the speaker*. 3dly, *Those words, the signs of these ideas*. 4thly, *Those signs put together*, by affirmation or negation, otherwise than the *ideas* they stand for are in the mind of the speaker. Since languages are made, *complex ideas* are usually got by the explication of those terms that stand for them: for since they consist of *simple ideas* combined, they may, by words standing for those *simple ideas*, be represented to the mind of one who understands those words, though that combination of *simple ideas* was never offered to his mind by the real existence of things.

Mixed modes have their *unity* from an act of the mind, combining those several *simple ideas* together, and considering them as one complex one: the mark of this union is one *name* given to that combination. Men seldom reckon any number of *ideas* to make one complex one: but such collections as there be names for. Thus the *killing of an old man*, is as fit to be united into one *complex idea*, as that of a *father*; yet there being no name for it, it is not taken for a particular complex *idea*, nor a distinct species of action from that of killing any other man.

Those collections of *ideas* have names generally affixed, which are of frequent use in conversation: in which cases men endeavour to communicate their thoughts to one another with all possible dispatch. Those others, which they have seldom occasion to mention, they tie not together, nor give them names.

This gives the reason, why there are words in every language, which cannot be rendered by any one single word of another. For the fashions and customs of one nation make several combinations of *ideas* familiar in one, which another had never any occasion to make. Such were *Ορεκτισμός* among the Greeks, *proscriptio* among the Romans. This also occasions the *constant change* of

languages; because the change of custom and opinions brings with it new combinations of *ideas*, which, to avoid long descriptions, have new names annexed to them, and so they become *new species of mixed modes*.

Of all our *simple ideas*, those that have had most *mixed modes* made out of them, are *thinking*, and *motion*; which comprehend in them all action; and *power*, from whence these actions are conceived to flow. For actions being the great business of mankind, it is no wonder, if the several modes of thinking and motion should be taken notice of, the *ideas* of them observed and laid up in memory, and have names assigned them. For without such *complex ideas* with names to them, men could not easily hold any communication about them. Of this kind are the modes of actions distinguished by their *causes*, *means*, *objects*, *ends*, *instruments*, *time*, *place*, and other circumstances; as also of the powers fitted for those actions: thus *boldness* is the power to do or speak what we intend, without fear or disorder; which power of doing any thing, when it has been acquired by the frequent doing the same thing, is that *idea* we call *habit*; when forward, and ready upon every occasion, to break into action, we call it *disposition*: thus *testiness* is a disposition or aptness to be angry.

Power being the source of all action, the substances wherein these powers are, when they exert this power, are called *causes*; and the substances thereupon produced, or the *simple ideas* introduced into any subject, *effects*. The efficacy whereby the new substance or *idea* is produced, is called, in the subject exerting that power, *action*; in the subject, wherein any *simple idea* is changed, or produced, *passion*: Which efficacy, in *intellectual agents*, we can conceive to be nothing else but modes of thinking and willing; in *corporeal agents*, nothing else but modifications of motion.

Of our complex ideas of substances.

THE mind observing several *simple ideas* to go constantly together, which being presumed to belong to one thing, are called, so united in one subject, by one name, which we are apt afterward to talk of and consider as one *simple idea*, which indeed is a complication of many *ideas* together. We imagine not these *simple ideas* to subsist by themselves; but suppose some *substratum* wherein they subsist, which we call *substance*. The *idea* of pure substance is nothing but the supposed (but unknown) support of these qualities, which are capable of producing *simple ideas* in us.

The *ideas of particular circumstances* are composed out of this obscure and general *idea* of substance, together with such combinations of *simple ideas* as are observed to exist together, and supposed to flow from the internal constitution and unknown essence of that substance. Thus we come by the *ideas of man, horse, gold, &c.* Thus the sensible qualities of *iron*, or a *diamond*, make the complex *ideas* of those substances, which a smith or a jeweller commonly knows better than a philosopher.

The same happens concerning the operations of the mind, *viz. thinking, reasoning, &c.* which we concluding not to subsist by themselves, nor apprehending how they can belong to body, or be produced by it, we think them

then the actions of some other substance, which we call *spirit*; of whose substance or nature we have as clear a notion as of that of body; the one being but the supposed *substratum* of the simple *ideas* we have from without, as the other of those operations which we experiment in ourselves within: So that the *idea* of *corporeal substance* in matter, is as remote from our conceptions as that of *spiritual substance*.

Hence we may conclude, that he has the perfectest *idea* of any particular substance, who has collected most of those simple *ideas* which do exist in it; among which we are to reckon its *active powers* and *passive capacities*, though not strictly simple *ideas*.

Secondary qualities, for the most part, serve to distinguish substances. For our senses fail us in the discovery of the *bulk*, *figure*, *texture*, &c. of the minute parts of bodies, on which their real constitutions and differences depend; and secondary qualities are nothing but powers, with relation to our senses. The *ideas* that make our complex ones of corporeal substances, are of three sorts: *First*, The *ideas* of primary qualities of things, which are discovered by our senses; such are *bulk*, *figure*, *motion*, &c. *Secondly*, The sensible secondary qualities; which are nothing but powers to produce several *ideas* in us by our senses. *Thirdly*, The aptness we consider in any substance, to cause or receive such alterations of primary qualities, as that the substance so altered should produce in us different *ideas* from what it did before; and they are called *active* and *passive powers*. All which, as far as we have any notice or notion of them, terminate in *simple ideas*.

Had we senses acute enough to discern the minute particles of bodies, it is not to be doubted, but they would produce quite different *ideas* in us; as we find in viewing things with *microscopes*. Such bodies as to our naked eyes are coloured and opaque, will through *microscopes* appear pellucid. *Blood* to the naked eye appears all red; but by a good *microscope* we see only some red globules swimming in a transparent liquor.

Besides these complex *ideas* we have of material substances; by the simple *ideas* taken from the operations of our own minds, which we experiment in ourselves, as *thinking*, *understanding*, *willing*, *knowing*, &c. co-existing in the same substance, we are able to frame the complex *idea* of a *spirit*. And this *idea* of an *immaterial substance*, is as clear as that we have of a *material*. By joining these with substance, of which we have no distinct *idea*, we have the *idea* of a *spirit*: And by putting together the *ideas* of coherent solid parts, and power of being moved, joined with substance, of which likewise we have no positive *idea*, we have the *idea* of *matter*. The one is as clear and distinct as the other. The substance of *spirit* is unknown to us; and so is the substance of body equally unknown to us. Two primary qualities or properties of body, *viz.* *solid coherent parts*, and *impulse*, we have distinct clear *ideas* of: So likewise have we of two primary qualities or properties of spirit, *viz.* *thinking*, and a *power of action*. We have also clear and distinct *ideas* of several qualities inherent in bodies, which are but the various modifications of the extension of coherent solid parts and their motion. We have likewise

the *ideas* of the several modes of thinking, *viz.* *Believing*, *doubting*, *hoping*, *fearing*, &c. as also of *willing* and *moving* the body consequent to it.

Of relation.

THERE is another set of *ideas* which the mind gets from the *comparing* of one thing with another. When the mind so considers one thing, that it does as it were bring it to and set it by another, and carries view from one to the other, this is *relation* or *respect*; and the denominations given to things intimating that respect, are what we call *relatives*, and the things so brought together *related*. Thus when I call CAJUS, *husband*, or *whiter*, I intimate some other person, or thing, in both cases, with which I compare him. Any of our *ideas* may be the foundation of relation.

Where languages have failed to give correlativenames, there the relation is not so easily taken notice of: As in *concubine*, which is a relative name as well as *wife*.

The *ideas* of relation may be same in those men who have far different *ideas* of the things that are related. Thus those who have different *ideas* of *man*, may agree in that of *father*.

There is no *idea* of any kind, which is not capable of an almost infinite number of considerations, in reference to other things; and therefore this makes no small part of mens words and thoughts. Thus one single man may at once sustain the relations of *father*, *brother*, *son*, *husband*, *friend*, *subject*, *general*, *European*, *Englishman*, *Islander*, *master*, *servant*, *bigger*, *less*, &c. to an almost infinite number; he being capable of as many relations, as there may be occasions of comparing him to other things in any manner of agreement, disagreement, or respect whatsoever.

Of cause and effect, and other relations.

THE *ideas* of *cause* and *effect* we get from our observation of the vicissitude of things, while we perceive some qualities or substances begin to exist, and that they receive their existence from the due application and operation of other beings: That which produces, is the *cause*; that which is produced, the *effect*. Thus fluidity in wax is the effect of a certain degree of heat, which we observe to be constantly produced by the application of such heat.

We distinguish the originals of things into two sorts.

First, When the thing is wholly made new, so that no part thereof did ever exist before, as when a new particle of matter doth begin to exist which had before no being, it is called *creation*.

Secondly, When a thing is made up of particles which did all of them before exist, but the thing so constituted of pre-existing particles, which all together make up such a collection of simple *ideas*, had not any existence before, as this *man*, this *egg*, this *rose*, &c. this, when referred to a substance produced in the ordinary course of nature by an internal principle, but set on work by some external agent, and working by insensible ways which we perceive not, is called *generation*: When the cause is extrinsic, and the effect produced by a sensible separation, or juxtaposition of discernible parts, we call it *making*; and such are all artificial things. When any simple *idea* is produced,

deed, which was not in that subject before, we call it *alteration*.

The denominations of things taken from *time*, are for the most part only relations. Thus when it is said that Queen *Elizabeth* lived sixty-nine, and reigned forty five years, no more is meant, than that the duration of her existence was equal to sixty-nine, and of her government to forty-five annual revolutions of the sun.

Young and old, and other words of time, that are thought to stand for positive *ideas*, are indeed relative; and intimate a relation to a certain length of duration, whereof we have the *idea* in our minds. Thus we call a man young or old, that has lived little or much of that time that men usually attain to. This is evident from our application of these names to other things; for a *man* is called young at twenty, but a *horse* old, &c. The sun and stars we call not old at all, because we know not what period God has set to that sort of beings.

There are other *ideas*, that are truly *relative*, which we signify by names that are thought *positive* and *absolute*; such as *great* and *little*, *strong* and *weak*. The things thus denominated, are referred to some standards, with which we compare them. Thus we call an *apple* *great*, that is bigger than the ordinary sort of those we have been used to; and a man *weak*, that has not so much strength or power to move, as men usually have.

Of identity and diversity.

ANOTHER occasion the mind takes of comparing, is the very *being of things*. When considering a thing as existing at any certain time, or place, and comparing it with itself as existing at any other time, &c. it forms the *idea* of *identity* and *diversity*. When we see any thing in any certain time and place, we are sure it is that very thing, and can be no other, how like soever it may be in all other respects.

We conceiving it impossible that two things of the same kind should exist together in the same place, we conclude, that whatever exists any where at the same time, excludes all of the same kind, and is there itself alone. When therefore we demand whether any thing be the *same*, or no, it refers always to something that existed such a time, in such a place, which it was certain at that instant was the same with itself and no other.

We have *ideas* of three sorts of substances: 1st, Of *God*; 2dly, *Finite intelligences*; 3dly, *Bodies*.

First, God being eternal, unalterable, and every where, concerning his *identity* there can be no doubt.

Secondly, Finite spirits having had their determinate time and place of beginning to exist, the relation to that time and place will always determine to each its *identity*, as long as it exists.

Thirdly, The same will hold of every particle of matter to which no addition or subtraction is made. These three exclude not one another out of the same place, yet each exclude those of the same kind out of the same place.

The identity and diversity of *modes* and *relations* are determined after the same manner that substances are; only the actions of finite beings, as *motion* and *thought*, consisting in succession, they cannot exist in different times and places as permanent beings: for no motion or thought,

considered as at different times, can be the same, each part thereof having a different beginning of existence.

From whence it is plain, that existence itself is the *principium individuationis*, which determinates a being to a particular time and place incommunicable to two beings of the same kind. Thus, suppose an *atom* existing in a determined time and place; it is evident that, considered in any instant, it is the same with itself, and will be so as long as its existence continues. The same may be said of two, or more, or any number of particles, whilst they continue together. The *mass* will be the same, however jumbled: but if one atom be taken away, it is not the same *mass*.

In *vegetables*, the identity depends not on the same *mass*, and is not applied to the same thing. The reason of this, is the difference between an animate body and *mass* of matter; *this* being only the cohesion of particles any how united; the *other*, such a disposition, an organization of parts, as is fit to receive and distribute nourishment, so as to continue and frame the wood, bark, leaves, &c. (of an *oak*, for instance) in which consists the vegetable life. That therefore which has such an organization of parts partaking of one common life, continues to be the same *plant*, though that life be communicated to new particles of matter, vitally united to the living plant. The case is not so much different in *brutes*, but that any one may hence see what makes an *animal*, and continues it the same.

The identity of the *same man* likewise consists in a participation of the same continued life in succeeding particles of matter vitally united to the same organized body.

To understand *identity* aright, we must consider what *idea* the word it is applied to stands for; it being one thing to be the *same substance*, another the *same man*, and a third the *same person*.

An *animal* is a living organized body; and the same *animal* is the same continued life communicated to different particles of matter, as they happen successively to be united to that organized living body; and our notion of *man* is but of a particular sort of animal.

Person stands for an intelligent being, that reasons and reflects, and can consider itself the same thing in different times and places; which it doth by that *consciousness* that is inseparable from thinking. By this every one is to himself what he calls *self*, without considering whether that *self* be continued in the same or divers substances. In this consists *personal identity*, or the sameness of a rational being; and so far as this consciousness extends backward to any past action or thought, so far reaches the identity of that person. It is the same *self* now, it was then: And it is by the same *self*, with this present one that now reflects on it, that that action was done.

Self is that conscious thinking thing, whatever substance it matters not, which is conscious of pleasure or pain, capable of happiness or misery; and so is concerned for itself as far as that consciousness extends. That with which the consciousness of this present thinking thing can join itself, makes the same person, and is one self with it; and so attributes to itself and owns all the actions of that thing as its own, as far as that consciousness reaches.

This *personal identity* is the subject of reward and punishment, being that by which every one is concerned for himself. If the *consciousness* went along with the little finger, when that was cut off, it would be the same self that was just before concerned for the whole body.

If the same *Socrates*, waking and sleeping, did not partake of the same consciousness, they would not be the same *person*. *Socrates* waking, could not be in justice accountable for what *Socrates* sleeping did, no more than one *twin* for what his brother *twin* did because their outides were so like that they could not be distinguished.

But suppose I wholly lose the memory of some parts of my life, beyond a possibility of retrieving them, so that I shall never be conscious of them again: Am I not the same *person* that did those actions, though I have now forgot them? I answer, that we must here take notice what the word *I* is applied to, which in this case is the man only: And the same man being presumed to be the same *person*, *I* is easily here supposed to stand also for the same *person*. But if it be possible for the same man to have distinct incommunicable consciousness at different times, it is past doubt the same man would, at different times, make different persons. Which we see is the sense of mankind in the solemnest declaration of their opinions, human laws not punishing the mad man for the sober man's actions, nor the sober man for what the mad man did; thereby making them two persons. Thus we say in *English*, such a one is *not himself*, or is *besides himself*; in which phrases it is insinuated, that *self* is changed, and the *self-same person* is no longer in that man.

But is not a man drunk or sober the same *person*? Why else is he punished for the same fact he commits when drunk, though he be never afterwards conscious of it? Just as much the same *person*, as a man that walks and does other things in his sleep is the same *person*, and is as answerable for any mischief he shall do in it. Human laws punish both with a justice suitable to their way of knowledge: Because in these cases they cannot distinguish certainly what is real, and what is counterfeit. And so the ignorance in drunkenness or sleep, is not admitted as a plea: For though punishment be annexed to personality, and personality to consciousness; and the drunkard, perhaps, is not conscious of what he did; yet human judicatures justly punish him, because the fact is proved against him, but want of consciousness cannot be proved for him.

To conclude: Whatever substance begins to exist, it must during its existence be the same. Whatever compositions of substances begin to exist, during the union of those substances, the concrete must be the same. Whatsoever mode begins to exist, during its existence it is the same. And so if the composition be of distinct substances, and different modes, the same rule holds.

Of other relations.

All simple *ideas*, wherein are parts or degrees, afford an occasion of comparing the subjects wherein they are to one another, in respect of those simple *ideas*. As

whiter, sweeter, more, less, &c. These depending on the equality and excess of the same simple *idea*, in several subjects, may be called *proportional relations*.

Another occasion of comparing things is taken from the circumstances of their origin, as *father, son, brother, &c.* These may be called *natural relations*.

Sometimes the foundation of considering things, is some act whereby any one comes by a moral right, power, or obligation to do something: Such are *general, captain, burgher*; these are *instituted and voluntary relations*, and may be distinguished from the *natural*, in that they are alterable and separable from the persons to whom they sometimes belonged, though neither of the substances so related be destroyed. But natural relations are not alterable, but are as lasting as their subjects.

Another relation is the conformity or disagreement of mens voluntary actions to a rule to which they are referred, and by which they are judged off: These may be called *moral relations*. It is this conformity or disagreement of our actions to some law (whereby good or evil is drawn on us from the will and power of the law maker, and is what we call *reward* or *punishment*) that renders our actions morally good or evil.

Of these moral *rules* or *laws*, there seem to be three sorts, with their different enforcements: first, *The divine law*; secondly, *Civil law*; thirdly, *The law of opinion or reputation*. By their relation to the first, our actions are either *sins* or *duties*; to the second, *criminal* or *innocent*; to the third, *virtues* or *vices*.

First, *The divine law*, is that law which God has set to the actions of men, whether promulgated to them by the light of nature, or the voice of revelation.

That God has given a law to mankind, seems undeniable; since he has, *first*, A right to do it; we are his creatures. *Secondly*, Goodness and wisdom, to direct our actions to what is best. *Thirdly*, Power to enforce it by reward, and punishment of infinite weight and duration. This is the only true touch-stone of moral rectitude; and by which men judge of the most considerable moral good or evil of their actions; that is, whether, as duties or sins, they are like to procure to them happiness or misery from the hands of the Almighty.

Secondly, *The civil law* is the rule set by the commonwealth to the actions of those that belong to it. This law nobody over-looks; the rewards and punishments being ready at hand to enforce it. extending to the protecting or taking away of the life, liberty, and estate of those who observe or disobey it.

Thirdly, *The law of opinion, or reputation*. *Virtue* and *vice* are names supposed every where to stand for actions in their own nature right and wrong. As far as they are really so applied, they so far are coincident with the divine law. But it is visible that these names in the particular instances of their application, through the several nations and societies of men, are constantly attributed only to such actions as in each country and society are in reputation or discredit. So that the measure of what is every where called and esteemed virtue and vice, is the approbation or dislike, praise or blame, which by a tacit consent establishes itself in the societies and tribes of men in the world;

world; whereby several actions come to find credit or disgrace amongst them, according to the judgment, maxims, or fashions of the place.

That this is so, appears hence: That though that passes for virtue in one place, which is elsewhere accounted vice, yet every where *virtue* and *praise*, *vice* and *blame*, go together: *Virtue* is every where that which is thought praiseworthy; and nothing else but that which has the allowance of public esteem, is called *virtue*. These have so close an alliance, that they are often called by the same name.

It is true, virtue and vice do, in a great measure, every where correspond with the unchangeable rule of right and wrong, which the laws of God have established; because the observation of these laws visibly secures and advances the general good of mankind, and the neglect of them breeds mischief and confusion: And therefore men, without renouncing all sense and reason, and their own interest, could not generally mistake in placing their commendation and blame on that side that deserved it not.

They who think commendation and disgrace not sufficient motives to engage men to accommodate themselves to the opinions and rules of those with whom they converse, seem little skilled in the history of mankind; the greatest part whereof govern themselves chiefly by this *law of fashion*.

The penalties that attend the breach of God's laws are seldom seriously reflected on; and those that do reflect on them entertain thoughts of future reconciliation; and for the punishment due from the laws of the commonwealth, men flatter themselves with the hopes of impunity: But no man escapes censure and dislike, who offends against fashion; nor is there one of ten thousand stiff and insensible enough, to bear up under the constant dislike and condemnation of his own club.

Morality then is nothing but a relation to these laws or rules: And these rules being nothing but a collection of several simple *ideas*, the conformity thereto is but so ordering the action, that the simple *ideas* belonging to it may correspond to those which the law requires. By which we see, how moral beings and notions are founded on, and terminated in the simple *ideas* of sensation and reflection. For example; let us consider the complex *idea* signified by the word *murder*. First, from reflection, we have the *ideas* of *willing*, *considering*, *purposing*, *malice*, &c. also of *life*, *perception*, and *self-motion*. Secondly, from sensation, we have the *ideas* of *man*, and of some action whereby we put an end to that perception and motion in the man: All which simple *ideas* are comprehended in the word *murder*.

This collection of simple *ideas* being found to agree or disagree with the esteem of the country I live in bred in, and to be held worthy of praise or blame, I call the action *virtuous* or *vicious*. If I have the will of a supreme invisible Law maker for my rule; then as I suppose the action commanded or forbidden by God, I call it good or evil, *sin* or *duty*: If a compare it with the civil law of my country, I call it *lawful* or *unlawful*, a crime or no crime.

Moral actions may be considered two ways:

First, As they are in themselves a collection of simple *ideas*; in which sense, they are positive absolute *ideas*.

Secondly, As good or bad, or indifferent: In this respect they are *relative*, it being their conformity or disagreement with some rule that makes them so. We ought carefully to distinguish between the positive *idea* of the action, and the reference it has to a rule: Both which are commonly comprehended under one name, which often occasions confusion, and misleads the judgment.

Thus the taking from another what is his, without his consent, is properly called *stealing*: But that name being commonly understood to signify also the moral pravity of the action, men are apt to condemn whatever they hear called *stealing* as an ill action disagreeing with the rule of right. And yet the private taking away his sword from a madman, to prevent his doing mischief, though it be properly denominated *stealing*, as the name of such a mixed mode, yet when compared to the law of God, it is no sin or transgression, though the name *stealing* ordinarily carries such an intimation with it.

Of real and fantastical ideas.

Our *ideas*, in reference to things from whence they are taken, or which they may be supposed to represent, come under a threefold distinction; and are, first, either *real* or *fantastical*; secondly, *adequate*, or *inadequate*; thirdly, *true* or *false*.

Real ideas, are such as have a foundation in nature, such as have a conformity with the real being and existence of things, or with their archetypes.

Fantastical are such as have no foundation in nature, nor any conformity with that reality of being to which they are referred as to their *archetypes*. By examining the several sorts of *ideas* we shall find, that, first our *simple ideas* are all real; not that they are images or representations of what does exist, but as they are the certain effects of powers in things without us, ordained by our Maker to produce in us such sensations: They are real *ideas* in us, whereby we distinguish the qualities that are really in things themselves.

Their reality lies in the steady correspondence they have with the distinct constitutions of real beings. But whether they answer to those constitutions as to *causes* or *patterns*, it matters not; it suffices, that they are constantly produced by them.

Complex ideas being arbitrary combinations of *simple ideas* put together, and united under one general name, in forming of which the mind uses its liberty, we must inquire which of these are real, and which imaginary combinations.

First, Mixed modes and relations having no other reality than what they have in the minds of men, nothing else is required to make them real, but a possibility of existing conformable to them. These *ideas* being themselves *archetypes*, cannot differ from their *archetypes*, and so cannot be chimerical; unless any one will jumble together in them inconsistent *ideas*. Those indeed that have names assigned them in any language, must have a conformity to the ordinary signification of the name that is given

given them, that they may not be thought fantastical.

Secondly, Our complex *ideas* of substances being made, in reference to things existing without us, whose representations they are thought are no farther real, than as they are such combinations of *simple ideas* as are really united, and co-exist in things without us: those are fantastical which are made up of several *ideas* that never were found united, as *Centaur*, &c.

Of ideas adequate or inadequate.

REAL *ideas* are either *adequate* or *inadequate*. First, *adequate*; which perfectly represent those archetypes which the mind supposes them taken from, and which it makes them to stand for. *Secondly*, *Inadequate*; which are such as do but partially or incompletely represent those archetypes to which they are referred. Whence it appears,

First, That all our *simple ideas* are *adequate*; for they being but the effects of certain powers in things fitted and ordained by God to produce such sensations in us, they cannot but be correspondent and adequate to such powers, and we are sure they agree to the reality of things.

Secondly, Our complex *ideas* of modes being voluntary collections of *simple ideas*, which the mind puts together without reference to any real archetypes, cannot but be *adequate ideas*. They are referred to no other pattern, nor made by any original, but the good-liking and will of him that makes the combination. If indeed one would conform his *ideas* to those which are formed by another person, they may be wrong or *inadequate*, because they agree not to that which the mind designs to be their archetype and pattern; in which respect only any *ideas* of modes can be wrong, imperfect, or inadequate.

Thirdly, Our *ideas* of substances have in the mind a double reference: *First*, They are sometimes referred to a supposed real essence, of each species of things; *secondly*, They are designed for representations in the mind, of things that do exist, by *ideas* discoverable in them: In both which respects they are *inadequate*.

First, If the names of substances stand for things, as supposed to have certain real essences, whereby they are of this or that species, of which real essences men are wholly ignorant; it follows, that the *ideas* they have in their minds, being referred to real essences as archetypes which are unknown, they must be so far from being adequate, that they cannot be supposed to be any representation of them at all. Our complex *ideas* of substances are nothing but certain collections of *simple ideas* that have been observed or supposed constantly to exist together. But such a complex *idea* cannot be the real essence of any substance: For then the properties we discover in it would be deducible from it, and their necessary connection with it, be known; as all the properties of a triangle depend on and are deducible from the complex *idea* of three lines including a space: But it is certain, that in our complex *ideas* of substances are not contained such *ideas* on which all other qualities that are to be found in them depend.

Secondly, Those that take their *ideas* of substances from their sensible qualities, cannot form adequate *ideas*

of them: Because their qualities and powers are so various, that no man's complex *idea* can contain them all. Most of our *simple ideas*, whereof our complex ones of substances do consist, are powers, which being relations to other substances, we cannot be sure we know all the powers, till we have tried what changes they are fitted to give and receive from other substances in their several ways of application; which being not possible to be tried upon one body, much less upon all, it is impossible we should have adequate *ideas* of any substance made of a collection of all its properties.

Of true and false ideas.

TRUTH and *falsehood*, in propriety of speech, belong only to propositions; and when *ideas* are termed *true* or *false*, there is some secret or tacit proposition which is the foundation of that denomination. Our *ideas* being nothing but appearances, or perceptions in the mind, can, in strictness of speech, no more be said to be true or false, than single names of things can be said to be true or false. The *idea* of *Centaur* has no more falsehood in it when it appears in our minds, than the name *Centaur* when it is pronounced or writ on paper. For truth or falsehood lying always in some affirmation or negation, our *ideas* are not capable, any of them, of being false, till the mind passes some judgment on them, that is, affirms or denies something of them. In a metaphysical sense they may be said to be true, that is, to be really such as they exist; though in things called true, even in that sense, there is perhaps a secret reference to our *ideas*, looked upon as the standards of that truth; which amounts to a mental proposition.

When the mind refers any of its *ideas* to any thing extraneous to it, they are then capable of being true or false: because in such a reference, the mind makes a tacit supposition of their conformity to that thing; which supposition, as it is true or false, so the *ideas* themselves come to be denominatd. This happens in these cases:

1st, When the mind supposes its *idea* conformable to that in other mens minds, called by the same name, such as that of *justice*, *virtue*, &c.

2^{dy}, When the mind supposes any *idea* conformable to some real existence. Thus, that of *Man* is true, that of *Centaur* false; the one having a conformity to what has really existed, the other not.

3^{dy}, When the mind refers any of its *ideas* to that real constitution and essence of any thing whereon all its properties depend: and thus the greatest part, if not all our *ideas* of substances are false.

As to the *first*, when we judge of our *ideas* by their conformity to those of other men, they may be any of them false: but *simple ideas* are least liable to be so mistaken. We seldom mistake green for blue, or bitter for sweet; much less do we confound the names belonging to different senses, and call a colour by the name of a taste. Complex *ideas* are much more liable to falsehood in this particular; and those of mixed modes more than substances: because in substances, their sensible qualities serve, for the most part, to distinguish them clearly; but in mixed modes we are more uncertain, and we may call that *justice* which ought to be called by another name. The reason

reason of this is, that the abstract *ideas* of mixed modes being mens voluntary combinations of such a precise collection of simple *ideas*, we have nothing else to refer our *ideas* of mixed modes as standards to, but the *ideas* of those who are thought to use names in their proper significations: and so as our *ideas* conform or differ from them, they pass for true or false.

As to the *second*. When we refer our *ideas* to the real existence of things, none can be termed false but our complex *ideas* of substances: for our simple *ideas* being nothing but perceptions in us answerable to certain powers in external objects, their truth consists in nothing but such appearances as are produced in us suitable to those powers: neither do they become liable to the imputation of falsehood, whether we judge these *ideas* to be in the things themselves, or no: for God having set them as marks of distinguishing things, that we may be able to discern one thing from another, and thereby chuse them as we have occasion, it alters not the nature of our simple *ideas*, whether we think the *idea* of *blue* (for instance) to be in the violet itself, or in the mind only: and it is equally from that appearance to be denominated *blue*, whether it be that real colour, or only a peculiar texture in it, that causes in us that *idea*; since the name *blue* notes properly nothing but that mark of distinction that is in a violet, discernible only by our eyes, whatever it consists in.

Neither would our simple *ideas* be *false*, if by the different structure of our organs it were so ordered, that the same object should produce in several mens minds different *ideas*: for this could never be known, since objects would operate constantly after the same manner. It is most probable, nevertheless, that the *ideas* produced by the same objects in different mens minds, are very near and undiscernibly like. Names of simple *ideas* may be misapplied; as a man, ignorant in the *English* tongue, may call *purple*, *scarlet*: but this makes no falsehood in the *idea*.

Complex *ideas* of modes cannot be false, in reference to the essence of any thing really existing; because they have no reference to any pattern existing, or made by nature.

Our complex *ideas* of substances, being all referred to patterns in things themselves, may be false. They are so, *1st*. When locked upon as representations of the unknown essences of things: *2^{dly}*. When they put together simple *ideas* which in the real existence of things have no union; as in *centaur*. *3^{dly}*. When from any collection of simple *ideas*, that do always exist together, there is separated, by a direct negation, any one simple *idea* which is constantly joined with them. Thus, if from extension, solidity, fixedness, malleableness, fusibility, &c. we remove the colour observed in *gold*: if this *idea* be only left out of the complex one of *gold*, it is to be looked on as an inadequate and imperfect, rather than a false one; since though it contains not all the simple *ideas* that are united in nature, yet it puts none together but what do really exist together.

Upon the whole, our *ideas*, as they are considered by the mind, either in reference to the proper signification of their names, or in reference to the reality of things, may more properly be called *right* or *wrong ideas*, according

as they agree or disagree to those patterns to which they are referred. The *ideas* that are in mens minds, simply considered, cannot be wrong, unless *complex ideas*, wherein inconsistent parts are jumbled together. All other *ideas* are in themselves right, and the knowledge about them right and true knowledge. But when we come to refer them to any patterns, or archetypes, then they are capable of being wrong, as far as they disagree with such archetypes.

Of the association of ideas.

SOME of our *ideas* have a natural correspondence and connection one with another: It is the office and excellency of our reason to trace these, and hold them together in that union and correspondence which is founded in their peculiar beings. Besides this, there is another connection of *ideas* wholly owing to chance or custom: *Ideas* that in themselves are not at all of kin, come to be so united in some mens minds, that it is very hard to separate them; they always keep company, and the one no sooner comes into the understanding, but its associate appears with it; and if they are more than two, the whole gang always inseparably shew themselves together. This strong combination of *ideas*, not allied by nature, the mind makes in itself either voluntarily, or by chance: And hence it comes in different men to be very different, according to their different inclinations, educations, interests, &c. Custom settles habits of thinking in the understanding, as well as of determining in the will, and of motions in the body; all which seem to be but trains of motion in the animal spirits, which, once set a going, continue on in the same steps they have been used to; which by often treading are worn into a smooth path, and the motion in it becomes easy, and, as it were, natural. As far as we can comprehend thinking, thus *ideas* seem to be produced in our minds; or if they are not, this may serve to explain their following one another in an habitual train, when once they are put into that track, as well as it does to explain such motions of the body.

This connection in our minds of *ideas*, in themselves loose and independent one of another, is of so great force to set us awry in our actions, as well moral as natural, passions, reasonings, and notions themselves, that perhaps there is not any one thing that deserves more to be looked after. Thus the *ideas* of *goblins* and *spirits* have really no more to do with darkness than light; yet let but a foolish maid inculcate these often on the mind of a child, and raise them there together, possibly he shall never be able to separate them again so long as he lives, but darkness shall ever afterwards bring with it those frightful *ideas*. A man has suffered pain or sickness in any place; he saw his friend die in such a room; though these have in nature nothing to do one with another, yet when the *idea* of the place occurs to his mind, it brings that of the pain and displeasure with it; he confounds him in his mind, and can as little bear the one as the other.

Intellectual habits and defects this way contracted, are not less frequent and powerful, though less observed. Let the *ideas* of *being* and *matter* be strongly joined either by education or much thought, whilst they are still combined in the mind, what notions, what reasonings will

there be about separate spirits? Let custom from the very childhood have joined figure and shape to the *idea* of God, and what absurdities will that mind be liable to about the Deity? Let the *idea* of *infallibility* be joined to any person, and these two constantly together possess the mind; and then one body in two places at once shall be swallowed for a certain truth, whenever that imagined infallible person dictates, and demands assent without inquiry.

Some such wrong combinations of *ideas* will be found to establish the irreconcilable opposition between different sects of philosophy and religion: for we cannot imagine every one of their followers to impose wilfully on himself, and knowingly refuse truth offered by plain reason. Interest, though it does a great deal in the case, yet cannot be thought to work whole societies of men to so universal a perverseness, as that every one of them should knowingly maintain falsehood; some at least must be allowed to do what all pretend to, *i. e.* to pursue truth sincerely. That therefore which captivates their reasons, and leads men of sincerity blindfold from common sense, will, when examined, be found to be what we are speaking of: some independent *ideas*, are by education, custom, and the constant din of their party, so coupled in their minds, that they always appear there together; and they can no more separate them in their thoughts, than if they were but one *idea*; and they operate as if they were so. This gives sense to jargon, demonstration to absurdities, and consistency to nonsense, and is the foundation of the greatest errors in the world. The confusion of two different *ideas*, which a customary connection of them in their minds hath to them in effect made but one, cannot but fill mens heads with false views, and their reasonings with false consequences.

Of knowledge in general.

SINCE the mind, in all its thoughts and reasonings, has no other immediate object but its own *ideas*, which alone it does or can contemplate, it is evident that our knowledge is only conversant about them. *Knowledge* then seems to be nothing but the perception of the connection and agreement, or disagreement and repugnancy of any of our *ideas*: where this perception is, there is *knowledge*; and where it is not, there, though we fancy, guess, or believe, yet we always come short of *knowledge*. When we know that *white* is not *black*, what do we but perceive that these two *ideas* do not agree? Or that the three angles of a *triangle*, are equal to two right ones; what do we more but perceive that equality to two right ones does necessarily agree to, and is inseparable from the three angles of a triangle? But to understand a little more distinctly wherein this agreement or disagreement consists, we may reduce it all to these four sorts: 1st, *Identity or diversity*; 2dly, *Relation*; 3dly, *Co-existence*; 4thly, *Real existence*.

1. *Identity or diversity*. It is the first act of the mind, to perceive its *ideas*; and so far as it perceives them, to know each what it is, and thereby to perceive their difference, that is, the one not to be the other: by this the mind clearly perceives each *idea* to agree with itself, and to be what it is; and all distinct

ideas to disagree. This it does without any pains or deduction, by its natural power of perception and distinction. This is what men of art have reduced to those general rules, *viz.* *what is, is*; and, *it is impossible for the same thing to be and not to be*. But no maxim can make a man know it clearer, that *round* is not *square*, than the bare perception of those two *ideas*, which the mind at first sight perceives to disagree.

2. The next sort of agreement or disagreement the mind perceives in any of its *ideas*, may be called *relative*, and is nothing but the perception of the relation between any two *ideas* of what kind soever; that is, their agreement or disagreement one with another in several ways the mind takes of comparing them.

3. The third sort of agreement or disagreement to be found in our *ideas*, is, *co-existence* or *non-co-existence* in the same subject; and this belongs particularly to substances. Thus when we pronounce concerning *gold*, that it is fixed, it amounts to no more but this, that fixedness, or a power to remain in the fire unconsumed, is an *idea* that always accompanies that particular sort of *yellowness*, *weight*, *fusibility*, &c. which make our complex *idea* signified by the word *gold*.

4. The fourth sort, is that of actual and *real existence* agreeing to any *idea*. Within these four sorts of agreement or disagreement, is contained all the knowledge we have, or are capable of. For all that we know or can affirm concerning any *idea*, is, That it is, or is not the same with some other; as, that *blue* is not *yellow*: That it does, or does not coexist with another in the same subject; as, that *iron* is *susceptible of magnetical impressions*: That it has that or this relation to some other *idea*; as, That two triangles, upon equal bases between two parallels, are equal: or, that it has a real existence without the mind; as, that *God* is.

There are several ways wherein the mind is possessed of truth, each of which is called knowledge. *First*, There is *actual knowledge*, when the mind has a present view of the agreement or disagreement of any of its *ideas*, or of the relation they have one with another. *Secondly*, A man is said to know any proposition, when having once evidently perceived the agreement or disagreement of the *ideas* whereof it consists, and so lodged it in his memory, that whenever it comes to be reflected on again, the mind assents to it without doubt or hesitation, and is certain of the truth of it. And this may be called *habitual knowledge*. And thus a man may be said to know all those truths which are lodged in his memory by a foregoing, clear, and full perception.

Of *habitual knowledge* there are two sorts: The one is of such truths laid up in the memory, as whenever they occur to the mind, it actually perceives the relation that is between those *ideas*. And this is in all those truths, where the *ideas* themselves, by an immediate view, discover their agreement or disagreement one with another. The other is of such truths, whereof the mind having been convinced, it retains the memory of the conviction, without the proofs. Thus a man that remembers certainly, that he once perceived the demonstration, that the three angles of a triangle are equal to two right ones, knows it to be true, when that demonstration is gone out

of his mind, and possibly cannot be recollected: But he knows it in a different way from what he did before, namely, not by the intervention of those intermediate *ideas*, whereby the agreement or disagreement of those in the proposition was at first perceived, but by remembering, *i. e.* knowing that he was once certain of the truth of this proposition, that the three angles of a triangle are equal to two right ones. The immutability of the same relations between the same immutable things, is now the *idea* that shews him, that if the three angles of a triangle were once equal to two right ones, they will always be so. And hence he comes to be certain, that what was once true, is always true; what *ideas* once agreed, will always agree; and consequently, what he once knew to be true, he will always know to be true, as long as he can remember that he once knew it.

Of the degrees of our knowledge.

ALL our knowledge consisting in the view the mind has of its own *ideas*, which is the utmost light and greatest certainty we are capable of, the different clearness of our knowledge seems to lie in the different way of perception the mind has of the agreement or disagreement of any of its *ideas*.

When the mind perceives this agreement or disagreement of two *ideas* immediately by themselves, without the intervention of any other, we may call it *intuitive knowledge*; in which cases the mind perceives truth, as the eye does light, only by being directed towards it. Thus the mind perceives, that *white is not black*; that *three are more than two*, and *equal to one and two*. This part of knowledge is irrefragible, and, like the bright sunshine, forces itself immediately to be perceived as soon as ever the mind turns its view that way. It is on this intuition that depends all the certainty and evidence of our other knowledge; which certainty every one finds to be so great, that he cannot imagine, and therefore not require a greater.

The next degree of knowledge, is, where the mind perceives not this agreement or disagreement immediately, or by the *juxta-position*, as it were, of the *ideas*, because those *ideas* concerning whose agreement or disagreement the inquiry is made, cannot by the mind be so put together, as to shew it. In this case the mind is fond to discover the agreement or disagreement which it searches, by the intervention of other *ideas*: And this is that which we call *reasoning*. And thus, if we would know the agreement or disagreement in bigness, between the three angles of a triangle, and two right angles, we cannot by an immediate view and comparing them do it; because the three angles of a triangle cannot be brought at once, and be compared with any other one or two angles. And so of this the mind has no immediate or intuitive knowledge. But we must find out some other angles, to which the three angles of a triangle have equality; and finding those equal to two right ones, we come to know the equality of these three angles to two right ones. Those intervening *ideas* which serve to shew the agreement of any two others, are called *proofs*; and where the agreement or disagreement is by this means plainly and clearly perceived, it is called *demonstration*. A quickness in the mind to find

those proofs, and to apply them right, is that which is called *fagacity*.

This knowledge, though it be certain, is not so clear and evident as *intuitive* knowledge. It requires pains and attention, and steady application of mind, to discover the agreement or disagreement of the *ideas* it considers; and there must be a progression by steps and degrees, before the mind can in this way arrive at certainty. Before demonstration there was a doubt, which, in *intuitive knowledge*, cannot happen to the mind that has its faculty of perception left to a degree capable of distinct *ideas*, no more than it can be a doubt to the eye (that can distinctly see *white* and *black*) whether this ink and paper be all of a colour.

Now, in every step that reason makes in *demonstrative knowledge*, there is an *intuitive knowledge* of that agreement or disagreement it seeks with the next intermediate *idea*, which it uses as a proof; for if it were not so, that yet would need a proof; since without the perception of such agreement or disagreement, there is no knowledge produced. By which it is evident, that every step in reasoning, that produces knowledge, has *intuitive certainty*: which when the mind perceives, there is no more required but to remember it, to make the agreement or disagreement of the *ideas* concerning which we inquire visible and certain. This *intuitive perception* of the agreement or disagreement of the intermediate *ideas* in each step and progression of the demonstration, must also be exactly carried in the mind; and a man must be sure that no part is left out; which because in long deductions the memory cannot easily retain, this knowledge becomes more imperfect than *intuitive*, and men often embrace falsehoods for demonstrations.

It has been generally taken for granted, that *mathematicks* alone are capable of demonstrative certainty. But to have such an agreement or disagreement as may be *intuitively* perceived, being not the privilege of the *ideas* of number, extension, and figure alone, it may possibly be the want of due method and application in us, and not of sufficient evidence in things, that demonstration has been thought to have so little to do in other parts of knowledge: For in whatever *ideas* the mind can perceive the agreement or disagreement immediately, there it is capable of *intuitive knowledge*: And where it can perceive the agreement or disagreement of any two *ideas*, by an *intuitive perception* of the agreement or disagreement they have with any intermediate *ideas*, there the mind is capable of demonstration which is not limited to the *ideas* of figure, number, extension, or their modes. The reason why it has been generally supposed to belong to them only, is, because in comparing their equality or excess the *modes* of numbers have every the least difference very clear and perceivable: And in *extension*, though every the least excess is not so perceptible, yet the mind has found out ways to discover the just equality of two angles, extensions, or figures; and both, that is, numbers and figures, can be set down by visible and lasting marks.

But in other simple *ideas*, whose modes and differences are made and counted by degrees, and not quantity, we have not so nice and accurate a distinction of their differences, as to perceive or find ways to measure their just equality,

equality, or the least differences: For those other simple *ideas* being appearances or sensations produced in us by the *size, figure, motion, &c.* of minute corpuscles singly insensible, their different degrees also depend on the variation of some, or all of those causes; which since it cannot be observed by us in particles of matter, whereof each is too subtle to be perceived, it is impossible for us to have any exact measures of the different degrees of these simple *ideas*. Thus, for instance, not knowing what number of particles, nor what motion of them, is fit to produce any precise degree of *whiteness*, we cannot demonstrate the certain equality of any two degrees of *whiteness*, because we have no certain standard to measure them by, nor means to distinguish every the least difference; the only help we have being from our senses, which in this point fail us.

But where the difference is so great as to produce in the mind *ideas* clearly distinct, *these ideas of colours*, as we see in different kinds, *blue* and *red*, (for instance,) are as capable of demonstration as *ideas* of number and extension. What is here said of colours, holds true in all secondary qualities. These two then, *intuition* and *demonstration*, are the degrees of our knowledge; whatever comes short of one of these, is but *faith* or *opinion*, not *knowledge*, at least, in all general truths. There is, indeed, another perception of the mind employed about the *particular existence of finite beings* without us; which going beyond probability, but not reaching to either of the foregoing degrees of certainty, passes under the name of *knowledge*.

Nothing can be more certain, than that the *idea* we receive from an external object is in our minds: This is *intuitive knowledge*; but whether we can thence certainly infer the existence of any thing without us, corresponding to that *idea*, is that whereof some men think there may be a question made, because men may have such an *idea* in their minds, when no such things exist, no such object affects their senses. But its evident that we are invincibly conscious to ourselves of a different perception, when we look upon the *sun* in the day, and think on it by night; when we actually taste *wormwood*, or smell a *rose*, or only think on that *favour* or *odour*. So that we may add to the two former sorts of knowledge, this also of the existence of particular external objects, by that perception and consciousness we have of the actual entrance of *ideas* from them, and allow these three degrees of knowledge, *viz. intuitive, demonstrative, and sensitive*.

But since our knowledge is founded on, and employed about our *ideas* only, will it follow thence that it must be conformable to our *ideas*; and that where our *ideas* are clear and distinct, obscure and confused, there our knowledge will be so too? *No*. For our knowledge consisting in the perception of the agreement or disagreement of any two *ideas*, its clearness or obscurity consists in the clearness or obscurity of that perception. and not in the clearness or obscurity of the *ideas* themselves. A man (for instance) that has a clear *idea* of the angles of a triangle, and of equality to two right ones, may yet have but an obscure perception of their agreement; and so have but a very obscure knowledge of it. But obscure and con-

fused *ideas* can never produce any clear or distinct knowledge; because, as far as any *ideas* are obscure or confused, so far the mind can never perceive clearly whether they agree or disagree.

Of the extent of human knowledge.

From what has been said concerning knowledge, it follows, *First*, That we can have no knowledge farther than we have *ideas*.

Secondly, That we have no knowledge farther than we can have perception of that agreement or disagreement of our *ideas*, either by *intuition, demonstration, or sensation*.

Thirdly, We cannot have an *intuitive* knowledge that shall extend itself to all our *ideas*, and all that we would know about them, because we cannot examine and perceive all the relations they have one to another, by juxtaposition, or an immediate comparison one with another. Thus we cannot *intuitively* perceive the equality of two extensions, the difference of whose figures makes their parts incapable of an exact immediate application.

Fourthly, Our *rational* knowledge cannot reach to the whole extent of our *ideas*; because between two different *ideas* we would examine, we cannot always find such *proofs* as we can connect one to another, with an *intuitive knowledge* in all the parts of the deduction.

Fifthly, *Sensitive* knowledge reaching no farther than the existence of things actually present to our senses, is yet much narrower than either of the former.

Sixthly, From all which it is evident, that the *extent of our knowledge*, comes not only short of the reality of *things*, but even of the extent of our own *ideas*. We have the *ideas* of a *square*, a *circle*, and *equality*; and yet, perhaps, shall never be able to find a *circle* equal to a *square*.

The affirmations or negations we make concerning the *ideas* we have, being reduced to the four sorts above mentioned, *viz. identity, coexistence, relation, and real existence*, we shall examine how far our knowledge extends in each of these.

First, As to *identity* and *diversity*, our *intuitive knowledge* is as far extended as our *ideas* themselves; and there can be no *idea* in the mind, which it does not presently, by an *intuitive knowledge*, perceived to be what it is, and to be different from any other.

Secondly, As to the agreement or disagreement of our *ideas* in *coexistence*: In this our knowledge is very short; though in this consists the greatest and most material part of our knowledge, concerning *substances*. For our *ideas* of *substances* being nothing but certain *collections of simple ideas, coexisting in one subject*, (our *idea* of *flame*, for instance, is a body *hot, luminous, and moving upward*;) when we would know any thing farther concerning this, or any other sort of substance, what do we but inquire what other qualities or powers these substances have, or have not? Which is nothing else but to know what other simple *ideas* do or do not *coexist* with those that make up that complex *idea*. The reason of this is, because the simple *ideas* which make up our complex *ideas* of substances, have no visible necessary connection

mediation or inconsistency with other simple *ideas* whose coexistence with them we would inform ourselves about. These *ideas* being likewise, for the most part, *secondary qualities*, which depend upon the *primary* qualities of their minute or insensible parts, or on something yet more remote from our comprehension, it is impossible we should know which have a necessary union or inconsistency one with another, since we know not the root from whence they spring, or the size, figure, and texture of parts on which they depend, and from which they result.

Besides this, there is no discoverable connection between any *secondary* quality, and those *primary* qualities that it depends on. We are so far from knowing what figure, size, or motion produces (for instance) a *yellow colour*, or *sweet taste*, or a *sharp sound*, that we can by no means conceive how any *size*, *figure*, or *motion* can possibly produce in us the *idea* of any *colour*, *taste*, or *sound* whatsoever; and there is no conceivable connection between the one and the other.

Our knowledge therefore of coexistence reaches little farther than *experience*. Some few, indeed, of the *primary* qualities have a necessary dependence and visible connection one with another; as *figure* necessarily supposes *extension*, *receiving* or *communicating motion* by *impulse* supposes *solidity*. But qualities coexistent in any subject, without this dependence and connection, cannot certainly be known to coexist any farther than *experience* by our senses informs us. Thus, though upon trial we find *gold* yellow, weighty, malleable, fusible, and fixed, yet because none of these have any evident dependence or necessary connection with the other, we cannot certainly know that where any *four* of these are, the *fifth* will be there also, how highly probable soever it may be: But the highest degree of *probability* amounts not to *certainity*; without which there can be no true knowledge: For this coexistence can be no further known, than it is perceived; and it cannot be perceived, but either, in *particular* subjects, by the observation of our senses, or, in *general*, by the necessary connection of the *ideas* themselves.

As to *incompatibility*, or *repugnancy to coexistence*, we may know that any subject can have of each sort of *primary* qualities but one particular at once, one *extension*, one *figure*; and so of sensible *ideas*, peculiar to each sense: for whatever of each kind is present in any subject, excludes all other of that sort; for instance, one subject cannot have *two smells* or *two colours* at the same time.

As to *powers of substances*, which make a great part of our inquiries about them, and are no inconsiderable branch of our knowledge; our knowledge as to these reaches little farther than *experience*; because they consist in a texture and motion of parts which we cannot by any means come to discover. *Experience* is that which in this part we must depend on; and it were to be wished that it were more improved.

As to the third sort, the *agreement or disagreement of our ideas in any other relation*, this is the largest field of knowledge, and it is hard to determinate how far it may extend. This part depending on our sagacity in finding intermediate *ideas* that may shew the habitudes and re-

lations of *ideas*, it is an hard matter to tell when we are at the end of such discoveries. They that are ignorant of *algebra*, cannot imagine the wonders in this kind that are to be done by it; and what farther improvements and helps advantageous to other parts of knowledge the sagacious mind of man may yet find out, it is not easy to determine. The *ideas* of *quantity* are not those alone that are capable of demonstration and knowledge; other, and perhaps more useful parts of contemplation, would undoubtedly afford us certainty, if vices, passions, and domineering interest, did not oppose or menace endeavours of this kind.

The *idea* of a *Supreme Being*, infinite in power, goodness, and wisdom, whose workmanship we are, and on whom we depend; and the *idea* of *ourselves*, as understanding rational creatures; would, if duly considered, afford such foundations of our *duty*, and *rules of action*, as might place *morality* among the sciences capable of demonstration. The relations of other modes may certainly be perceived, as well as those of number and extension. Where there is no *property*, there is no *injustice*. is a proposition as certain as any demonstration in *Euclid*: for the *idea* of *property* being a right to any thing; and the *idea* of *injustice* being the invasion or violation of that right; it is evident, that these *ideas* being thus established, and these names annexed to them, we can as certainly know this proposition to be true, as that a *triangle has three angles equal to two right ones*. Again, *No government allows absolute liberty*. The *idea* of *government* being the establishment of society upon certain rules or laws which require conformity to them, and the *idea* of *absolute liberty* being for any one to do whatever he pleases, we are as capable of being certain of the truth of this proposition, as of any in *mathematics*.

What has given the advantage to the *ideas* of *quality*, and made them thought more capable of certainty and demonstration, is,

First, That they can be represented by sensible marks which have a nearer correspondence with them than any words or sounds. *Diagrams* drawn on paper are copies of the *ideas*, and not liable to the uncertainty that words carry in their signification: But we have no sensible marks that resemble our *moral ideas*, and nothing but words to express them by; which though when written they remain the same, yet the *ideas* they stand for may change in the same man; and it is very seldom that they are not different in different persons.

Secondly, *Moral ideas* are commonly more complex than figures. Whence these two inconveniences follow: *First*, That their names are of more uncertain signification; the precise collection of simple *ideas* they stand for not being so easily agreed on, and so the sign that is used for them in communication always, and in thinking often, does not steadily carry with it the same *idea*. *Secondly*, The mind cannot easily retain those precise combinations so exactly and perfectly as is necessary; in the examination of the habitudes and correspondences, agreements or disagreements of several of them one with another, especially where it is to be judged off by long deductions, and the intervention of several other complex *ideas*, to shew the agreement or disagreement of two remote ones.

Now one part of these disadvantages in *moral ideas*, which has made them be thought not capable of demonstration, may in a good measure be remedied by *definitions*, setting down that collection of simple *ideas* which every term shall stand for, and then using the terms steadily and constantly for that precise collection.

As to the fourth sort of knowledge, *viz. of the real actual existence of things*, we have an *intuitive* knowledge of our own existence; a *demonstrative* knowledge of the existence of God; and a *sensitive* knowledge of the objects that present themselves to our senses.

From what has been said, we may discover the causes of our ignorance; which are chiefly these three: *First*, Want of ideas; *Secondly*, Want of a discoverable connection between the ideas we have; *Thirdly*, Want of tracing and examining our ideas.

First, There are some things we are ignorant of for want of ideas. All the simple ideas we have are confined to the observations of our senses, and the operations of our own minds that we are conscious of in ourselves. What other ideas it is possible other creatures may have, by the assistance of other senses and faculties more or perfecter than we have, or different from ours, it is not for us to determine; but to say or think there are no such, because we conceive nothing of them, is no better an argument, than if a blind man should be positive in it, that there was no such thing as sight and colours, because he had no manner of idea of any such thing. What faculties therefore other species of creatures have to penetrate into the nature and inmost constitutions of things, we know not. This we know, and certainly find, that we want other views of them, besides those we have, to make discoveries of them more perfect. The intellectual and sensible world are in this perfectly alike, that the parts which we see of either of them, hold no proportion with that we see not; and whatsoever we can reach with our eyes or our thoughts of either of them, is but a point almost nothing in comparison of the rest.

Another great cause of ignorance, is the want of ideas that we are capable of. This keeps us in ignorance of things we conceive capable of being known. Bulk, figure, and motion we have ideas of; yet not knowing what is the particular bulk, motion, and figure of the greatest part of the bodies of the universe, we are ignorant of the several powers, efficacies, and ways of operation, whereby the effects we daily see are produced. These are hid from us in some things, by being too remote; in others, by being too minute.

When we consider the vast distance of the known and visible parts of the world, and the reasons we have to think that what lies within our ken is but a small part of the immense universe, we shall then discover an huge abyss of ignorance. What are the particular fabrics of the great masses of matter, which make up the whole stupendous frame of corporeal beings; how far they are extended; and what is their motion, and how continued; and what influence they have upon one another; are contemplations, that at first glimpse our thoughts lose themselves in. If we confine our thoughts to this little system of our sun, and the grosser masses of matter that visibly move about it; what several sorts of vegetables,

animals, and intellectual corporeal beings, infinitely differ from those of our little spot of earth, may probably be in other planets, to the knowledge of which, even of their outward figures and parts, we can no way attain, whilst we are confined to this earth, there being no natural means, either by sensation or reflection, to convey their certain ideas into our minds?

There are other bodies in the universe, no less concealed from us by their minuteness. These insensible corpuscles being the active parts of matter, and the great instruments of nature on which depend all their secondary qualities and operations, our want of precise distinct ideas of their primary qualities keeps us in incurable ignorance of what we desire to know about them. Did we know the mechanical affections of *rhubarb* and *opium*, we might as easily account for their operations of *purging* or *causing sleep*, as a watchmaker can for the motions of his watch. The dissolving of silver in *aqua fortis*, or gold in *aqua regia*, and not vice versa, would be then, perhaps, no more difficult to know, than it is to a smith to understand why the turning of one key will open a lock, and not the turning of another. But whilst we are destitute of senses acute enough to discover the minute particles of bodies, and to give us ideas of their mechanical affections, we must be content to be ignorant of their properties and operations: Nor can we be assured about them any farther than some few trials we make are able to reach; but whether they will succeed again another time, we cannot be certain. This hinders our certain knowledge of universal truths concerning natural bodies; and our reason carries us herein very little beyond particular matters of fact. And therefore, how far soever human industry may advance useful and experimental philosophy in physical things, yet scientific will still be out of our reach; because we want perfect and adequate ideas of those very bodies which are nearest to us, and most under our command.

This, at first sight, shews us how disproportionate our knowledge is to the whole extent, even of material beings; to which if we add the consideration of that infinite number of spirits that may be, and probably are, which are yet more remote from our knowledge, whereof we have no cognizance; we shall find this cause of ignorance conceal from us, in an impenetrable obscurity, almost the whole intellectual world, a greater certainly, and a more beautiful world than the material: For bating some very few ideas of spirit we get from our own mind by reflection, and from thence the best we can collect of the Father of all spirits, the Author of them and us and all things, we have no certain information so much as of the existence of other spirits but by revelation; much less have we distinct ideas of their different natures, states, powers, and several constitutions, wherein they agree or differ one from another, and from us: And therefore in what concerns their different species and properties, we are under an absolute ignorance.

The second cause of ignorance, is the want of discoverable connection between those ideas we have: Where we want that, we are utterly incapable of universal and certain knowledge: and are, as in the former case, left only to observation and experiment. Thus the mechanical

nical affections of bodies having no affinity at all with the *ideas* they produce in us, we can have no distinct knowledge of such operations beyond our experience; and can reason no otherwise about them, than as the effects or appointment of an infinitely wise agent, which perfectly surpasses our comprehensions.

The operation of our minds upon our bodies, is as inconceivable. How any *thought* should produce a motion in *body*, is as remote from the nature of our *ideas*, as how any *body* should produce any *thought* in the *mind*. That it is so, if experience did not convince us, the consideration of the things themselves would never be able in the least to discover to us.

In some of our *ideas* there are certain relations, habits, and connections, so visibly included in the nature of the *ideas* themselves, that we cannot conceive them separable from them by any power whatsoever: In these only we are capable of certain and universal knowledge. Thus the *idea* of a *right-lined triangle*, necessarily carries with it an *equality of its angles to two right ones*. But the coherence and continuity of the parts of matter, the production of sensation in us of *colours* and *sounds*, &c. by impulse and motion, being such wherein we can discover no natural connection with any *ideas* we have, we cannot but ascribe them to the arbitrary will and good pleasure of the wise Architect.

The things that we observe constantly to proceed regularly, we may conclude to act by a law set them; but yet by a law that we know not; whereby, though causes work steadily, and effects constantly flow from them, yet their connections and dependencies being not discoverable in our *ideas*, we can have but an experimental knowledge of them.

The *third* cause of ignorance, is our *want of tracing those ideas we have* or may have, and finding out those intermediate *ideas* which may shew us what habitude of agreement or disagreement they may have one with another: And thus many are ignorant of *mathematical* truths, for want of application in inquiring, examining, and by due ways comparing those *ideas*.

Hitherto we have examined the *extent* of our knowledge, in respect of the several sorts of beings that are: There is another *extent* of it, in respect of *universality*, which will also deserve to be considered; and in this regard our knowledge follows the nature of our *ideas*. If the *ideas* are *abstract*, whose agreement or disagreement we perceive, our knowledge is *universal*. For what is known of such general *ideas*, will be true of every particular thing in which that *essence*, that is, *abstract idea*, is to be found: And what is once known of such *ideas*, will be perpetually, and for ever true. So that, as to all general knowledge, we must search and find it only in our own minds: And it is only the examining of our own *ideas* that furnishes us with that. Truths belonging to essences of things, (that is, to *abstract ideas*), are *eternal*, and are to be found out by the contemplation only of those essences, as the existence of things is to be known only from experience.

Of the reality of our knowledge.

THE reader by this time may be ready to object, If

it be true, that all knowledge lies only in the perception of the agreement or disagreement of our own *ideas*, the visions of an *enthusiast*, and the reasonings of a *sober* man, will be equally certain: It is no matter how things are, so a man observe but the agreement of his own imaginations, and talk conformably; it is all truth, all certainty.

To this it is answered, that if our knowledge of our *ideas* should terminate in them, and reach no farther, where there is something farther intended. our most ferocious thoughts would be of little more use than the *reveries* of a crazy brain. But it is evident, that this way of *certainty*, by the knowledge of our own *ideas*, goes a little farther than bare imagination: and that all the certainty of general truths a man has, lies in nothing else but this knowledge of our *ideas*.

It is evident, that the mind knows not things immediately, but by the intervention of the *ideas* it has of them. Our knowledge therefore is *real*, only so far as there is a conformity between our *ideas* and the reality of things. But how shall we know when our *ideas* agree with things themselves? There are *two sorts of ideas*, that we may be assured agree with things: These are,

First, *Simple ideas*; which since the mind can by no means make to itself, must be the effect of things operating upon the mind in a natural way, and producing therein those perceptions, which, by the will of our Maker, they are ordained and adapted to. Hence it follows, that *simple ideas* are not fictions of our fancies, but the natural and regular productions of things without us, really operating upon us; which carry with them all the conformity our state requires, which is to represent things under those appearances they are fitted to produce in us. Thus the *idea of whiteness*, as it is in the mind, exactly answers that power which is in any body to produce it there. And this conformity between our *simple ideas*, and the existence of things, is sufficient for real knowledge.

Secondly, All our *complex ideas*, except those of substances, being *archetypes* of the mind's own making, and not referred to the existence of things as to their originals, cannot want any conformity necessary to real knowledge: For that which is not designed to represent any thing but itself, can never be capable of a wrong representation. Here the *ideas* themselves are considered as *archetypes*, and things no otherwise regarded than as they are conformable to them. Thus the *mathematician* considers the truth and properties belonging to a *rectangle*, or *circle*, only as they are *ideas* in his own mind, which possibly he never found existing mathematically, that is, precisely true; yet his knowledge is not only certain, but *real*; because real things are no farther concerned, nor intended to be meant by any such propositions, than as things really agree to those *archetypes* in his mind. It is true of the *idea* of a *triangle*, that its *three angles are equal to two right ones*: It is true also of a *triangle*, wherever it exists: What is true of those *figures* that have barely an *ideal* existence in his mind, will hold true of them also when they come to have a *real* existence in matter.

Hence it follows, that *moral* knowledge is as capable of *real certainty* as *mathematicks*: For *certainty* being nothing

nothing but the perception of the agreement or disagreement of our *ideas*, and demonstration nothing but the perception of such agreement by the intervention of other *ideas*, our *moral ideas*, as well as *mathematical*, being *archetypes* themselves, and so adequate or complete *ideas*, all the agreement or disagreement we shall find in them will produce *real knowledge*, as well as in *mathematical figures*. That which is requisite to make our knowledge certain, is the clearness of our *ideas*; and that which is required to make it *real*, is, that they answer their *archetypes*.

Thirdly, But the complex *ideas*, which we refer to *archetypes* without us, may differ from them, and so our knowledge about them may come short of being *real*; and such are our *ideas of substances*. These must be taken from something that does or has existed, and not be made up of *ideas* arbitrarily put together, without any real pattern. Herein, therefore, is founded the reality of our knowledge concerning *substances*, that all our complex *ideas* of them must be such, and such only, as are made up of such simple ones as have been discovered to coexist in nature. And our *ideas* being thus true, tho' not perhaps very exact copies, are the subjects of the *real knowledge* of them. Whatever *ideas* we have, the agreement we find they have with others will be knowledge. If those *ideas* be abstract, it will be *general knowledge*. But to make it *real* concerning *substances*, the *ideas* must be taken from the real existence of things. Wherever, therefore, we perceive the agreement or disagreement of our *ideas*, there is *certain knowledge*: And wherever we are sure those *ideas* agree with the reality of things, there is *certain real knowledge*.

Of truth in general.

TRUTH, in the proper import of the word, signifies the joining or separating of signs, as the things signified by them do agree or disagree one with another. The joining or separating of signs, is what we call *propositions*; so that *truth* properly belongs only to *propositions*: Whereof there are two sorts, *mental* and *verbal*; as there are two sorts of signs commonly made use of, *ideas* and *words*.

It is difficult to treat of *mental propositions* without *verbal*; because, in speaking of *mental*, we must make use of *words*, and then they become *verbal*. Again, men commonly in their thoughts and reasonings use *words* instead of *ideas*; especially if the subject of their meditation contains in it complex *ideas*. If we have occasion to form *mental propositions* about *white*, *black*, *circle*, &c. we can, and often do, frame in our minds the *ideas* themselves, without reflecting on the *names*: But when we would consider, or make propositions about the more complex *ideas*, as of a *man*, *vitriol*, *fortitude*, *glory*, &c. we usually put the *name* for the *idea*; because the *idea* these *names* stand for being for the most part confused, imperfect, and undetermined, we reflect on the *names* themselves, as being more clear, certain, and distinct, and readier to occur to our thoughts, than pure *ideas*; and so we make use of these *words* instead of the *ideas* themselves, even when we would meditate and reason within ourselves, and make tacit *mental propositions*.

We must then observe two sorts of *propositions* that we are capable of making: *First*, *Mental propositions*, wherein the *ideas* in our understandings are put together or separated by the mind perceiving or judging of their agreement or disagreement. *Secondly*, *Verbal propositions*; which are words put together or separated in affirmative or negative sentences: So that *proposition* consists in joining or separating signs; and *truth* consists in putting together or separating these signs, according as the things they stand for agree or disagree.

Truth, as well as knowledge, may well come under the distinction of *verbal* and *real*; that being only *verbal truth*, wherein terms are joined according to the agreement or disagreement of the *ideas* they stand for, without regarding whether our *ideas* are such as really have or are capable of having an existence in nature. But then it is they contain *real truth*, when these signs are joined as our *ideas* agree: and when our *ideas* are such as, we know, are capable of having an existence in nature; which in substances we cannot know, but by knowing that such have existed. *Truth* is the marking down in words the agreement or disagreement of *ideas* as it is: *Falseness* is the marking down in words the agreement or disagreement of *ideas* otherwise than it is; and so for as these *ideas*, thus marked by sounds, agree to their *archetypes*, so far only is the *truth real*. The knowledge of this *truth* consists in knowing what *ideas* the words stand for, and the perception of the agreement or disagreement of those *ideas*, according as it is marked by those words.

Besides *truth* taken in the strict sense before mentioned, there are other sorts of *truths*: As, *first*, *Moral truth*; which is speaking things according to the persuasion of our own minds. *Secondly*, *Metaphysical truth*; which is nothing but the real existence of things conformable to the *ideas* to which we have annexed their names.

These considerations of *truth* either having been before taken notice of, or not being much to our present purpose, it may suffice here only to have mentioned them.

Of our knowledge of existence.

HITHERTO we have only considered the *essences* of things; which being only *abstract ideas*, and thereby removed in our thoughts from particular existence, give us no knowledge of *existence* at all. We proceed now to inquire concerning our *knowledge of the existence* of things, and how we come by it.

We have the knowledge of our own *existence* by *intuition*; of the *existence* of *God*, by *demonstration*; and of other things, by *sensation*. As for our own *existence*, we perceive it so plainly, that it neither needs, nor is capable of any proof. *I think, I reason, I feel pleasure and pain*: can any of these be more evident to me than my own *existence*? If I doubt of all other things, that very doubt makes me perceive my own *existence*, and will not suffer me to doubt of that. If I know I doubt, I have as certain a perception of the thing doubting, as of that thought which I call *doubt*. Experience then convinces us, that we have an *intuitive knowledge of our own existence*; and an internal infallible perception that we are. In every act of sensation, reasoning, or thinking, we are conscious to ourselves of our own being; and

and in this matter need not short of the highest degree of certainty.

Of our knowledge of the existence of a God.

THOUGH *God* has given us no *innate ideas* of himself, yet having furnished us with those faculties our minds are endowed with, he hath not left himself without a witness, since we have sense, perception, and reason, and cannot want a clear proof of him as long as we carry ourselves about us. Nor can we justly complain of our ignorance in this great point, since he has so plentifully provided us with means to discover and know him, so far as is necessary to the end of our being, and the great concernment of our happiness. But though this be the most obvious truth that reason discovers, yet it requires thought and attention; and the mind must apply itself to a regular deduction of it, from some part of our *intuitive knowledge*; or else we shall be as ignorant of this, as of other propositions which are in themselves capable of clear demonstration. To shew, therefore, that we are capable of knowing, that is, *being certain, that there is a God*, and how we may come by this certainty, we need go no farther than ourselves, and that undoubted knowledge we have of our own existence. It is beyond question, that *man has a clear perception of his own being*: He knows certainly that he exists, and that he is something. In the next place, man knows by an *intuitive certainty, that bare nothing can no more produce any real being, than it can be equal to two right angles*. If therefore, we know there is some real being, it is an evident demonstration, that *from eternity there has been something*; since what was not from eternity had a beginning; and what had a beginning, must be produced by something else. Next, it is evident, that *what has its being from another, must also have all that which is in and belongs to its being from another too*: All the powers it has, must be owing to, and received from the same source. This eternal source then of all being must be also the source and original of all power; and so this *eternal Being* must be also the *most powerful*.

Again, man finds in himself *perception and knowledge*: We are certain, then, that there is not only some being, but some knowing intelligent being in the world. There was a time, then, when there was no knowing being, or else there has been a knowing being from eternity. If it be said, there was a time when that eternal being had no knowledge; the reply is, that then it is impossible there should have ever been any knowledge; it being as impossible that things wholly void of knowledge. and operating blindly, and without any perception, should produce a knowing being, as it is that a triangle should make itself three angles bigger than two right ones.

Thus from the consideration of ourselves, and what we infallibly find in our own constitutions, our reason leads us to the knowledge of this certain and evident truth, that *there is an eternal, most powerful, and knowing being*; and from this *idea* duly considered, will easily be deduced all those other attributes we ought to ascribe to this eternal being.

From what has been said, it is plain, we have a more certain knowledge of the existence of a *God*, than of any

thing our senses have not immediately discovered to us; nay, that we more certainly know that there is a *God*, than that there is any thing else without us.

It being then unavoidable for all rational creatures to conclude, that *something has existed from eternity*: let us next see what *kind of thing* that must be. There are but two sorts of beings in the world, that man knows or conceives. *First*, Such as are purely material, without sense or perception, as the clippings of our beards, and parings of our nails. *Secondly*, Sensible perceiving beings; such as we find ourselves to be. These two sorts we shall hereafter call *cogitative* and *incogitative* beings: Which to our present purpose are better than *material* and *immaterial*.

If then there must be something *eternal*, it is very obvious to reason, that it must necessarily be a *cogitative* being; because it is as impossible to conceive that ever bare *incogitative* matter should produce a *thinking* intelligent being, as that nothing should of itself produce matter. Let us suppose any parcel of matter *eternal*, we shall find it in itself unable to produce any thing. Let us suppose its parts firmly at rest together: If there were no other being in the world, must it not eternally remain so, a dead inactive lump? Is it possible to conceive it can add motion to itself, or produce any thing? *Matter* then by its own strength cannot produce in itself so much as *motion*. The motion it has must also be from eternity, or else added to matter by some other being more powerful than matter. But let us suppose motion eternal too; yet matter, *incogitative* matter and motion, could never produce *thought*: *Knowledge* will still be as far beyond the *power of motion* and *matter* to produce, as matter is beyond the power of nothing to produce. Divide *matter* into as minute parts as you will, vary the figure and motion of it as much as you please, it will operate no otherwise upon other bodies of proportionable bulk, than it did before this division. The minutest particles of matter knock, impel, and resist one another, just as the greater do; and that is all they can do. So that if we will suppose *nothing eternal, matter can never begin to be*: If we suppose *bare matter* without motion eternal, *motion can never begin to be*: If we suppose only matter and motion eternal, *thought can never begin to be*: For it is impossible to conceive that matter, either with or without motion, could have originally, in and from itself sense, perception, and knowledge; as is evident from hence, that then sense, perception and knowledge, must be a property eternally inseparable from matter and every particle of it. Since therefore whatsoever is the first eternal being, must necessarily be *cogitative*; and whatsoever is first of all things, must necessarily contain in it, and actually have, at least all the perfections that can ever after exist, it necessarily follows, that the *first eternal being cannot be matter*.

If therefore it be evident that something necessarily must exist from eternity, it is also evident, that that *something must necessarily be a cogitative being*: For it is as impossible that *incogitative matter* should produce a *cogitative being*, as that nothing, or the negation of all being, should produce a positive being or matter.

This discovery of the necessary existence of an Eternal

mind does sufficiently lead us into the knowledge of *God*. For it will hence follow, that all other knowing beings that have a beginning must depend on him, and have no other ways of knowledge or extent of power than what he gives them; and therefore if he made those, he made also the less excellent pieces of this universe, all *inanimate bodies*, whereby his *omniscience*, power, and providence, will be established; and from thence all his other attributes necessarily follow.

Of our knowledge of the existence of other things.

THE knowledge of our own being we have by *intuition*: The existence of a *God*, *reason* clearly makes known to us. *The knowledge of the existence of any other thing*, we can have only by *sensation*; for there being no necessary connection of *real existence* with any *idea* a man hath in his memory; nor of any other existence, but that of *God*, with the existence of any particular man; no particular man can know the existence of any other being, but only when, by actually operating upon him, it makes itself be perceived by him. The having the *idea* of any thing in our mind, no more proves the existence of that thing, than the picture of a man evidences his being in the world, or the visions of a dream make thereby a true history. It is therefore the actual receiving of *ideas* from without, that gives us notice of the existence of other things, and makes us know that something doth exist at that time without us, which causes that *idea* in us, though perhaps we neither know nor consider how it does it; for it takes not from the *certainty* of our senses, and the *ideas* we receive by them, that we know not the manner wherein they are produced. This notice we have by our *senses* of the existing of things without us, though it be not altogether so certain as *intuition* and *demonstration*, deserves the name of knowledge, if we persuade ourselves that our faculties act and inform us right concerning the existence of those objects that affect them. But besides the assurance we have from our *senses* themselves, that they do not err in the information they give us of the existence of things without us, we have other concurrent reasons: As, *First*, It is plain those perceptions are produced in us by exterior causes affecting our senses, because those that want the *organs* of any *sense* never can have the *ideas* belonging to that sense produced in their minds. This is too evident to be doubted; and therefore we cannot but be assured, that they come in by the organs of that sense, and no other way.

Secondly, Because we find sometimes that we cannot avoid the having those *ideas* produced in our minds. When my eyes are shut, I can at pleasure recall to my mind the *ideas* of *light*, or the *sun*, which former sensations had lodged in my memory: But if I turn my eyes towards the *sun*, I cannot avoid the *ideas* which the *light* or the *sun* then produces in me. Which shews a manifest difference between those *ideas* laid up in the memory, and such as force themselves upon us and we cannot avoid having. And therefore it must needs be some exterior cause, whose efficacy I cannot resist, that produces those *ideas* in my mind whether I will or no.

Besides, there is nobody who doth not perceive the difference in himself, between actually looking upon the

sun, and contemplating the *idea* he has of it in his memory; and therefore he hath certain knowledge, that they are not both memory or fancy, but that actual seeing has a cause without.

Thirdly, Add to this, that many *ideas* are produced in us with pain, which we afterwards remember without the least offence. Thus the pain of *heat* or *cold*, when the *idea* of it is received in our minds, gives us no disturbance, which, when felt, was very troublesome; and we remember the pain of *hunger*, *thirst*, *head-ach*, &c. without any pain at all, which would either never disturb us, or else constantly do it, as often as we thought of it, were there nothing more but *ideas* floating in our minds, and appearances entertaining our fancies, without the real existence of things affecting us from abroad.

Fourthly, Our *senses* in many cases bear witness to the truth of each other's report concerning the existence of sensible things without us: he that doubts when he sees a *fire*, whether it be *real*, may, if he please, feel it too; and by the exquisite pain he will be convinced, that it is not a bare *idea* or *phantom*.

If after all this, any one will be so *sceptical*, as to distrust his senses, and to question the existence of all things, or our knowledge of any thing, let him consider that the certainty of things existing *in rerum natura*, when we have the testimony of our senses for it, is not only as great as our frame can attain to, but as our condition needs. For our *faculties* being not suited to the full extent of being, nor a clear comprehensive knowledge of all things, but to the preservation of us in whom they are, and accommodated to the use of life; they serve our purpose well enough, if they will but give us certain notice of those things that are convenient or inconvenient to us: For he that sees a *candle* burning, and has experienced the force of the flame, by putting his finger in it, will little doubt that this is something existing without him which does him harm, and puts him to pain; which is assurance enough; when no man requires greater certainty to govern his actions by, than what is as certain as his actions themselves: So that this evidence is as great as we can desire, being as certain to us as our pleasure or pain, that is, *happiness* or *misery*; beyond which we have no concernment either of knowing or being.

In fine, when our *senses* doth actually convey into our understandings any *idea*, we are assured that there is something at that time *really existing* without us. But this knowledge extends only as far as the present testimony of our senses, employed about particular objects, that do then affect them, and no farther. My seeing a *man* a minute since, is no certain argument of his present existence.

As when our *senses* are actually employed about any object, we know that it does exist; so by our memory we may be assured, that heretofore things that affected our *senses* have existed: And thus we have the knowledge of the past existence of several things whereof our senses having informed us, our memories still retain the *ideas*: and of this we are past all doubt, so long as we remember well.

As to the existence of *spirits*, our having *ideas* of them does not make us know that any such things do exist without

without us, or that there are any *finite spirits*, or any other *spiritual beings* but the *eternal God*. We have ground from *revelation*, and several other reasons, to believe with assurance, that there are such creatures: But our senses not being able to discover them, we want the means of knowing their particular existence; for we can no more know that there are *finite spirits* really existing, by the *ideas* we have of such beings, than by the *ideas* any one has of *fairies*, or *centaurs*, he can come to know, that things answering those *ideas* do really exist.

Hence we may gather, that there are *two sorts* of propositions: One concerning the existence of any thing answerable to such an *idea*, as that of an *elephant*, *phoenix*, *motion*, or *angel*, viz. whether such a thing does any where exist: And this knowledge is only of *particulars*, and not to be had of any thing without us, but only of *God*, any other way than by our *senses*.

Another sort of proposition is, wherein is expressed the agreement or disagreement of our *abstract ideas*, and their dependence one on another. And these may be *universal* and certain: so having the *idea* of *God* and my *self*, of *fear* and *obedience*, I cannot but be sure that *God* is to be *feared* and *obeyed* by me: and this proposition will be certain concerning *man* in general, if I have made an *abstract idea* of such a *species*, whereof I am one particular. But such a proposition, how certain soever, proves not to me the existence of men in the world; but will be true of all such creatures, whenever they do exist: which *certainity* of such general propositions, depends on the agreement or disagreement discoverable in those *abstract ideas*. In the former case, our knowledge is the consequence of the *existence* of things producing *ideas* in our minds by our senses: in the latter, the consequences of the *ideas* that are in our minds, and producing these general propositions, many whereof are called *eternal verities*: and all of them indeed are so; not from being written all or any of them in the minds of all men, or that they were any of them propositions in any one's mind, till he, having got the *abstract ideas*, joined or separated them by affirmation or negation; but whereforever we can suppose such a creature as *man* is, endowed with such faculties, and thereby furnished with such *ideas* as we have, we must conclude he must needs, when he applies his thoughts to the consideration of his *ideas*, know the truth of certain propositions that will arise from the agreement or disagreement he will perceive in his own *ideas*. Such propositions being once made about *abstract ideas*, so as to be true, they will, whenever they can be supposed to be made again, at any time past, or to come, by a mind having those *ideas*, always be true: for names being supposed to stand perpetually for the same *ideas* and the same *ideas* having immutably the same habitudes one to another, propositions concerning any *abstract ideas* that are once true must needs be *eternal verities*.

Of judgment.

THE *understanding faculties* being given to man, not barely for speculation, but also for the conduct of his life, a man would be at a great loss, if he had nothing to direct him but what has the certainty of true knowledge.

He that will not *eat* till he has demonstration that it will nourish him, nor *sleep* till he is infallibly assured of success in his business, will have little else to do but *sit still*, and *perish*.

Therefore as *God* hath set some things in broad daylight; as he has given us some certain knowledge, though limited to a few things, in comparison, (probably as a taste of what *intellectual* creatures are capable of, to excite in us a desire and endeavour after a better state;) so in the greatest part of our concernment, he has afforded us only the twilight of probability, suitable to that state of *mediocrity* and *probationership* he has been pleased to place us in here.

The faculty which *God* has given *man* to enlighten him, next to certain knowledge, is *judgment*; whereby the mind takes its *ideas* to agree or disagree, without perceiving a demonstrative evidence in the proofs. The mind exercises this judgment sometimes out of necessity, where demonstrative proofs and certain knowledge are not to be had; and sometimes out of *laziness*, unskilfulness, or haste, even where they are to be had.

This faculty of the mind, when it is exercised immediately about things, is called *judgment*; when about truths delivered in words, is most commonly called *assent* or *dissent*. Thus the mind has *two faculties* conversant about truth and falsehood: First, *Knowledge*; whereby it certainly perceives, and is undoubtedly satisfied of the agreement or disagreement of any *ideas*. Secondly, *Judgment*, which is the putting *ideas* together, or separating them from one another in the mind, when their certain agreement or disagreement is not perceived, but presumed to be so. And if it so unites or separates them as in reality things are, it is *right judgment*.

Of probability.

PROBABILITY is nothing but the appearance of the agreement or disagreement of two *ideas*, by the intervention of proofs, whose connection is not constant and immutable, or is not perceived to be so; but is or appears for the most part to be so; and is enough to induce the mind to judge the proposition to be *true* or *false*, rather than the contrary.

Of probability there are degrees, from the neighbourhood of *certainty* and *demonstration*, quite down to *improbability* and *unlikeliness*, even to the confines of *impossibility*: And also degrees of *assent* from certain knowledge, and what is next it, full assurance and confidence, quite down to conjecture, doubt, distrust, and disbelief.

That proposition then is *probable*, for which there are arguments or proofs to make it pass or be received for *true*: The entertainment the mind gives to this sort of propositions, is called *belief*, *assent*, or *opinion*. *Probability* then being to supply the defect of our knowledge, is always conversant about propositions whereof we have no *certainty*, but only some inducements to receive them for true. The grounds of it are, in short, *these two* following.

First, The conformity of any thing with our own knowledge, experience, or observation.

Secondly, The testimony of others, vouching their observation and experience. In the testimony of others is

to be considered, *First*, The number; *Secondly*, The integrity; *Thirdly*, The skill of the witnesses; *Fourthly*, The design of the author, if it be a testimony cited out of a book; *Fifthly*, The consistency of the parts and circumstances of the relation; *Sixthly*, Contrary testimonies.

The mind, before it rationally *assents* or *dissents* to any probable proposition, ought to examine all the grounds of *probability*, and see how they make, more or less, for or against it; and upon a due balancing of the whole, reject or receive it, with a more or less firm *assent*, according to the preponderancy of the greater grounds of *probability* on one side, or the other.

Of the degrees of assent.

THE grounds of *probability*, laid down in the foregoing section, as they are the foundations on which our *assent* is built, so are they also the measure whereby its several degrees are (or ought to be) regulated. Only we are to take notice, that no grounds of probability operate any farther on the mind, which searches after truth, and endeavours to judge right, than they appear, at least, in the first judgment or search that the mind makes. It is indeed in many cases impossible, and in most very hard, even for those who have admirable memories, to retain all the proofs which, upon a due examination, made them embrace that side of the question. It suffices, that they have once, with care and fairness, sifted the matter as far as they could; and having once found on which side the *probability* appeared to them, they lay up the conclusion in their memories, as a *truth* they have discovered; and for the future remain satisfied with the testimony of their memories, that this is the opinion, that, by the proofs they have once fecd of it, deserves such a degree of their *assent* as they assent it.

It is unavoidable then that the memory be relied on in this case, and that men be persuaded of several *opinions*, whereof the proofs are not actually in their thoughts, nay, which perhaps they are not able actually to recall: Without this the greatest part of men must be either *sceptics*, or change every moment, when any one offers them arguments which for want of memory, they are not presently able to answer.

It must be owned, that mens sticking to past judgments, is often the cause of great *obstinacy* in error and mistake. But the fault is not that they rely on their memories for what they have before well judged; but because they judged before they had well examined. Who almost is there that hath the leisure, patience, and means, to collect together all the proofs concerning most of the opinions he has, so as safely to conclude, that he has a clear and full view, and that there is no more to be alledged for his better information? And yet we are forced to determine ourselves on one side, or other: The conduct of our lives, and the management of our great concerns, will not bear delay: For those depend, for the most part, on the determination of our judgment in points, wherein we are not capable of certain knowledge, and wherein it is necessary for us to embrace one side or the other.

The propositions we receive upon inducements of *probability*, are of two sorts: *First*, Concerning some parti-

cular existence, or matter of *fact*, which falling under our observation, is capable of *human testimony*: *Secondly*, Concerning things which, being beyond the discovery of our *senses*, are not capable of human testimony.

Concerning the first of these, *viz. Particular matter of fact*.

First, Where any particular thing, consonant to the constant observation of ourselves, and others, in the like case, comes attested with the concurrent reports of all that mention it, we receive it as easily, and build as firmly upon it, as if it were certain knowledge. Thus, if all *Englishmen*, who have occasion to mention it, should report, that it froze in *England* last winter, or the like, a man would as little doubt of it, as that *seven and four are eleven*.

The *first* and *highest* degree of *probability* then is, when the general consent of all men, in all ages, as far as can be known, concurs with a man's own constant experience in the like cases, to confirm the truth of any particular matter of fact, attested by fair witnesses: Such are the stated *constitutions* and *properties* of bodies, and the regular proceedings of *causes* and *effects* in the ordinary course of *nature*. This we call an *argument* from the nature of things themselves: For what we and others always observe to be after the same manner, we conclude with reason to be the effects of steady and regular *causes*, though they come not within the reach of our knowledge; as that fire warmed a man, or made *lead fluid*; that *iron* sunk in water, swam in quicksilver. A relation affirming any such thing to have been, or a predication that it will happen again in the same manner, is received without doubt or hesitation; and our *belief* thus grounded, rises to *assurance*.

Secondly, The next degree of *probability*, is when by my own experience, and the agreement of all others that mention it, a *thing* is found to be for the most part so; and that the particular instance of it is attested by many and undoubted *witnesses*. Thus *history* giving us such an account of men in all ages, and my own experience confirming it, that most men prefer their own private advantage to the public; if all historians that write of *Tiberius*, say that he did so, it is extremely probable: And in this case, our *assent* rises to a degree which we may call *confidence*.

Thirdly, In matters happening indifferently, as that a *bird* should fly this or that way; when any particular matter of fact comes attested by the concurrent testimony of unsuspected *witnesses*, there our *assent* is also unavoidable. Thus, that there is in *Italy* such a city as *Rome*; that about one thousand and seven hundred years ago there lived such a man in it as *Julius Cæsar*, &c. a man can as little doubt of this, and the like, as he does of the being and actions of his own acquaintance, whereof he himself is a witness.

Probability, on these grounds, carries so much evidence with it, that it leaves us as little liberty to believe or disbelieve, as demonstration does, whether we will know or be ignorant. But the difficulty is, when testimonies contradict common experience, and the reports of witnesses clash with the ordinary course of nature, or with one another; here diligence, attention, and exactness, is required

quired to form a *right judgment*, and to proportion the *assent* to the evidence and *probability* of the thing, which rises and falls according as the two foundations of credibility favour or contradict it. These are liable to such variety of contrary observations, circumstances, reports, tempers, designs, over-sight, &c. of reporters, that it is impossible to reduce to precise rules the various degrees wherein men give their *assent*. This in general may be said, that as the *proofs*, upon due examination, shall to any one appear in a greater or less degree to preponderate on either side, so they are fitted to produce in the mind such different entertainments, as are called *belief*, *conjecture*, *guess*, *doubt*, *wavering*, *distrust*, *disbelief*, &c.

It is a rule generally approved, that any testimony, the farther off it is removed from the original truth, the less force it has: And in *traditional* truths, each remove weakens the force of the *proof*. There is a rule quite contrary to this, advanced by some men, who look on *opinions* to gain force by growing *older*. Upon this ground, propositions evidently false or doubtful in their first beginning, come by an inverted *rule of probability* to pass for *authentic* truths; and those which deserved little credit from the mouths of their first relators, are thought to grow *venerable* by age, and are urged as undeniable.

But certain it is, that no *probability can rise above its first original*. What has no other evidence than the single testimony of *one witness*, must stand or fall by his *only* testimony, though afterwards cited by hundreds of others; and is so far from receiving any strength thereby, that it becomes the weaker; because passion, interest, inadvertency, mistake of his meaning, and a thousand odd reasons, which capricious mens minds are acted by, may make one man quote another's words or meaning wrong. This is certain, that what in one age was affirmed upon slight grounds, can never after come to be more valid in future ages by being often repeated.

The second sort of *probability*, is concerning things not falling under the reach of our senses, and therefore not capable of testimony: And such are,

1st, The existence, nature, and operations of *finite immaterial* beings without us, as *spirits*, *angels*, &c. or the existence of *material* beings, such as, for their smallness or remoteness, our *senses* cannot take notice of; as whether there be any *plants*, *animals*, &c. in the *planets*, and other mansions of the vast universe.

2^{dly}, Concerning the manner of operation in most parts of the works of *nature*; wherein though we see the sensible *effects*, yet their causes are unknown, and we perceive not the ways and manner how they are produced. We see *animals* are generated, nourished, and move; the *loadstone* draws *iron*, &c. But the causes that operate, and the manner they are produced in, we can only guess, and probably conjecture. In these matters *analogy* is the only help we have; and it is from that alone we draw all our grounds of *probability*. Thus observing, that the bare rubbing of two bodies violently upon one another, produces *heat*, and very often *fire*, we have reason to think, that what we call *heat* and *fire* consists in a certain violent agitation of the imperceptible minute parts of the burning matter. This sort of *probability*, which is the best con-

duct of rational experiments, and the rise of *hypotheses*, has also its use and influence. And a wary reasoning from *analogy* leads us often into the discovery of *truths* and *useful deductions*, which would otherwise lie concealed.

Though the common experience, and the ordinary course of things, have a mighty influence on the minds of men, to make them give or refuse credit to any thing proposed to their belief; yet there is one case wherein the strangeness of the fact lessens not the *assent* to a fair testimony given of it. For where such supernatural events are suitable to ends aimed at by Him who has the power to change the course of nature, there, under such circumstances, they may be the fitter to procure belief, by how much the more they are beyond or contrary to ordinary observation. This is the proper case of *miracles*; which, well attested, do not only find credit themselves, but give it also to other *truths*.

There are propositions that challenge the highest degree of our *assent* upon bare testimony, whether the thing proposed agree or disagree with common experience and the ordinary course of things or no: The reason whereof is, because the testimony is of such an one as cannot deceive nor be deceived; and that is *God* himself. This carries with it certainty beyond doubt, evidence beyond exception. This is called by a peculiar name, *revelation*, and our *assent* to it, *faith*, which has as much certainty in it as our knowledge itself; and we may as well doubt of our own being, as we can whether any *revelation* from *God* be true. So that *faith* is a settled and sure principle of *assent* and *assurance*, and leaves no manner of room for doubt or hesitation; only we must be sure, that it be a *divine revelation*, and that we understand it right, else we shall expose ourselves to all the extravagancy of *enthusiasm*, and all the error of wrong principles, if we have *faith* and *assurance* in what is not *divine revelation*.

Of reason.

THE word *reason*, in *English*, has different significations. Sometimes it is taken for *true* and *clear principles*; sometimes for *clear* and *fair deductions* from those principles; sometimes for the *cause*, and particularly for the *final cause*: But the consideration we shall have of it here, is as it stands for a *faculty* whereby *man* is supposed to be distinguished from *beasts*, and wherein it is evident he much surpasses them.

Reason is necessary, both for the enlargement of our knowledge, and regulating our assent; for it hath to do both in knowledge and opinion, and is necessary and assisting to all our other intellectual faculties; and indeed contains *two* of them, *viz.* first, *Sagacity*, whereby it finds intermediate *ideas*; secondly, *Illation*, whereby it so orders and disposes of them, as to discover what connection there is in each link of the chain, whereby the extremes are held together, and thereby, as it were, to draw into view the truth sought for; which is that we call *illation*, or *inference*, and consists in nothing but the perception of the connection there is between the *ideas* in each step of the deduction; whereby the mind comes to see either the certain agreement or disagreement of any

two *ideas*, as in *demonstration*, in which it arrives at knowledge; or their probable connection, on which it gives or with-holds its *assent*, as in *opinion*.

Sense and *intuition* reach but a little way: The greatest part of our knowledge depends upon deductions and intermediate *ideas*. In those cases where we make true propositions for true, without being certain of their being so, we have need to find out, examine, and compare the grounds of their *probability*: In both cases, the faculty which finds out the means, and rightly applies them to discover certainty in the one, and probability in the other, is that which we call *reason*: So that in reason we may consider these four degrees; *first*, The discovering and finding out of proofs; *secondly*, The regular and methodical disposition of them, and laying them in such order as their connection may be plainly perceived; *thirdly*, The perceiving their connection; *fourthly*, The making a right conclusion.

There is one thing more which deserves to be considered concerning *reason*; and that is, whether *syllogism*, as is generally thought, be the proper instrument of it; and the usefulest way of exercising this faculty. The causes to doubt of it, are these:

First, Because *syllogism* serves our *reason* but in one only of the forementioned parts of it; and that is, to shew the connection of the proofs of any one instance, and no more: But in this it is of no great use, since the mind can perceive such connection, where it really is, as easily, nay perhaps better, without it. We may observe, that there are many men that reason exceeding clear and rightly, who know not how to make a *syllogism*: And scarce any one make *syllogisms* in reasoning within himself. Indeed, sometimes they may serve to discover a fallacy, hid in a *rhetorical* flourish; or by stripping an absurdity of the cover of wit and good language, shew it in its naked deformity: But the weakness or fallacy of such a loose discourse it shews, by the artificial form it is put into, only to those who have thoroughly studied *modes* and *figure*, and have so examined the many ways that three propositions may be put together, as to know which of them does certainly conclude right, and which not, and upon what grounds it is that they do so: But they who have not so far looked into those forms, are not sure, by virtue of *syllogism*, that the conclusion certainly follows from the premises; the mind is not taught to reason by these *rules*; it has a native faculty to perceive the coherence or incoherence of its *ideas*, and can range them right without any such perplexing *repetitions*.

And to shew the weakness of an argument, there needs no more but to strip it of the superfluous *ideas*, which, blended and confounded with those on which the inference depends, seem to shew a connection where there is none, or at least do hinder the discovery of the want of it; and then to lay the naked *ideas*, on which the force of the argumentation depends, in their due order; in which position the mind, taking a view of them, sees what connection they have, and is able to judge of the inference without any need of *syllogism* at all.

Secondly, Because *syllogisms* are not less liable to fallacies than the plainer ways of argumentation. And for

this we appeal to common observation, which has always found these artificial methods of reasoning more adapted to catch and entangle the mind, than to instruct and inform the understanding. And if it be certain that fallacy can be couched in *syllogisms*, as it cannot be denied, it must be something else, and not *syllogism*, that must discover them: But if men skilled in and used to *syllogisms*, find them assisting to their reason in the discovery of truth, we think they ought to make use of them. All that we aim at is, that they should not ascribe more to these forms than belongs to them; and think that men have no use, or not so full a use, of their reasoning faculty without them.

But however it be in knowledge, it is of far less, or no use at all in *probabilities*: For the *assent* there being to be determined by the preponderancy, after a due weighing of all the proofs on both sides, nothing is so unfit to assist the mind in that as *syllogism*; which running away with one assumed *probability*, pursues that till it has led the mind quite out of sight of the thing under consideration.

But let it help us (as perhaps may be said) in *convincing men of their errors or mistakes*: yet full it fails our reason in that part, which if not its highest perfection, is yet certainly its hardest task, and that which we most need its help in; and that is, the *finding out of proofs, and making new discoveries*. This way of reasoning discovers no new proofs, but is the art of marshalling and ranging the old ones we have already. A man knows first, and then he is able to prove *sylogistically*; so that *sylogism* comes after knowledge; and then a man has little or no need of it. But it is chiefly by the finding out those *ideas* that shew the connection of distant ones, that our stock of knowledge is increased, and that useful arts and sciences are advanced.

Reason, though of a very large extent, fails us in several instances; as, *first*, Where our *ideas* fail. *Secondly*, It is often at a loss, because of the obscurity, confusion, nor imperfection of the *ideas* it is employed about. Thus having no perfect *idea* of the least extension of *matter*, or of *infinity*, we are at a loss about the divisibility of *matter*. *Thirdly*, Our *reason* is often at a stand, because it perceives not these *ideas*, which would serve to shew the certain or probable agreement or disagreement of any two other *ideas*. *Fourthly*, Our *reason* is often engaged in absurdities and difficulties, by proceeding upon false principles, which being followed, lead men into contradictions to themselves, and inconsistency in their own thoughts. *Fifthly*, Dubious words, and uncertain signs, often puzzle *mens reason*, and bring them to a nonplus.

Though the deducing one proposition from another, be a great part of reason, and that which it is usually employed about; yet the principal act of ratiocination, is the finding the agreement or disagreement of two *ideas* one with another, by the intervention of a third; as a man, by a yard, finds two houses to be of the same length, which could not be brought together to measure their equality by *juxta-position*: Words have their consequences as the signs of such *ideas*; and things agree or disagree, as really they are; but we observe it only by our *ideas*.

In reasoning, men ordinarily use *four* sorts of arguments.

The *first* is to alledge the opinions of men, whose parts, learning, eminency, power, or some other cause, has gained a name, and settled their reputation in the common esteem with some kind of authority: This may be called *argumentum ad verecundiam*.

Secondly, Another way is, to require the adversary to admit what they alledge as a proof, or to assign a better: This is called *argumentum adignorantiam*.

A *third* way, is to press a man with consequences drawn from his own principles or concessions: This is known under the name of *argumentum ad hominem*.

Fourthly, The using of proofs drawn from any of the foundations of knowledge or probability: This is called *argumentum ad iudicium*. This alone, of all the four, brings true instruction with it, and advances us in our way to knowledge: For, *first*, It argues not another man's opinion to be right, because I, out of respect, or any other consideration but that of conviction, will not contradict him. *Secondly*, It proves not another man to be in the right way, nor that I ought to take the same with him, because I know not a better. *Thirdly*, Nor does it follow, that another man is in the right way, because he has shewn me that I am in the wrong: This may dispose me, perhaps, for the reception of truth, but helps me not to it; that must come from *proofs and arguments*, and light arising from the nature of things themselves; not from my shame-facedness, ignorance, or error.

M E T

METAPLASMUS, in grammar, a transmutation or change made in a word, by adding, retrenching, or altering a letter or syllable thereof.

METASTASIS, in medicine, a transposition or settlement of some humour or disease on some other part; and sometimes it signifies such an alteration of a disease as is succeeded by a solution.

METATARSUS, in anatomy. See *ANATOMY*, p. 187.

METATHESIS, in grammar, a species of the metaplasmos; being a figure whereby the letters or syllables of a word are transposed, or shifted out of their usual situation, as pistis for pritis.

METEMPSYCHOSIS, the doctrine of transmigration, which supposes that human souls, upon leaving the body, become the souls of such kind of brutes as they most resemble in their manners.

This was the doctrine of Pythagoras and his followers; who, held that the souls of vicious men were imprisoned in the bodies of miserable beasts, there to do penance for several ages, at the expiration whereof they returned again to animate men; but if they had lived virtuously, some happier brute, or even a human creature, was to be their lot. What led Pythagoras into this opinion was the persuasion he had that the soul was not of a perishable nature; whence he concluded, that it must move into some other upon its abandoning this. Lucan the poet, who was

By what has been said of *reason*, we may be able to make some guess at the distinction of things into those that are according to, above, and contrary to *reason*. According to *reason*, are such propositions whose truth we can discover by examining and tracing those *ideas* we have from *sensation* and *reflection*, and by natural deduction find to be true or probable. Above *reason*, are such propositions, whose *truth* or *probability* we cannot by *reason* derive from those principles. Contrary to *reason*, are such propositions as are inconsistent with, or irreconcilable to our clear and distinct *ideas*. Thus the *existence* of one God, is according to *reason*; the *existence* of more than one God, contrary to *reason*; the *resurrection* of the body after death, above *reason*. Above *reason*, may be also taken in a double sense, viz. Above *probability*, or, above *certainity*: In that large sense also, contrary to *reason* is sometimes taken.

There is another use of the word *reason*, wherein it is opposed to *faith*; which, though authorised by common use, yet is it in itself a very improper way of speaking; for *faith* is nothing but a firm assent of the mind; which, if it be regulated as is our duty, cannot be afforded to any thing but upon good *reason*, and so cannot be opposite to it: He that believes without having any reason for believing, may be in love with his own fancies; but neither seeks *truth* as he ought, nor pays the obedience due to his Maker, who would have him use those discerning faculties he has given him, to keep him out of mistake and error.

M E T

contrived to mitigate the apprehension of death, by persuading men that they only changed their lodgings, and ceased to live only to begin a new life.

METEMTOSIS, a term in chronology, expressing the solar equation, necessary to prevent the new moon from happening a day too late; by which it is opposed to *proemptosis*, which signifies the lunar equation necessary to prevent the new moon from happening a day too soon.

METEOR, in physiology, an imperfect, changeable, and mixt body, or the resemblance of a body appearing in the atmosphere, and formed by the action of the heavenly bodies, out of the common elements.

Meteors are of three kinds; fiery, airy, and watery. Fiery meteors consist of a fat sulphureous smoke set on fire; such as falling stars, draco volans, the ignis fatuus, and other phenomena, appearing in the air. Airy meteors consist of stultent and spirituous exhalations, such as winds, &c. Watery meteors are composed of vapours, or watery particles, variously modified by heat and cold, such as clouds, rain, hail, snow and dew.

METHEGLIN, a drink prepared of honey, one of the most pleasant and general drinks the northern parts of Europe afford. It is, according to Bailey, made as follows: Put as much new honey naturally running from the comb, into spring water, as that, when the honey is thoroughly dissolved, an egg will not sink to the bottom, but be just suspended in it. Then boil the liquor

For an hour or more, till such time as the egg swim above the liquor; then take it off the fire, and let it cool. When very cool, next morning, it may be barrell'd up; and adding to it half an ounce of ginger, as much of cloves, as much of mace, and a quarter of an ounce of cinnamon, all grossly pounded, a spoonful of yeast may be added also at the bung to increase its fermentation. When it has done working, it may be closely stopp'd up; and after it has stood a month, it may be drawn off into bottles.

METHOD, the arrangement of our ideas in such a regular order, that their mutual connection and dependence may be readily comprehended.

METHODISTS, a name at first given to a society of religious young men at Oxford, and now applied to all those who adhere to the doctrine of the church of England as taught by Whitefield, Wesley, &c. They are said to be, in general, plain well-meaning people, who do not dissent from the established church; but profess to live with great purity, according to her articles. At their first appearance their teachers were charged, in the heat of their zeal, with several irregularities, and many expressions in their preaching which were not altogether unexceptionable; but as the civil government, with a moderation and wisdom peculiar to the present time, thought fit to overlook their behaviour, they have since honestly acknowledged wherein they were mistaken; and, in consequence of the perfect liberty of conscience they enjoy, have fused into a more regular and peaceable conduct, agreeable to the genuine spirit of Christianity.

METHODISTS, *Methodici*, is also an appellation given to a sect of ancient physicians, who reduced the whole healing art to a few common principles or appearances.

METONYMY, in rhetoric, is a trope in which one name is put for another, on account of the near relation there is between them. By this trope any of the most significant circumstances of a thing are put for the thing itself. The metonymy is used with most advantage in the following cases. 1. When the narration stands for the action, and what the poet or historian describes he is said to do; which is a lively manner of expression, exceeding the common, as much as action goes beyond description, or life excels painting. 2. When the name of any relation is put for the duty it requires, and the benevolence and tenderness that may be expected from it. Thus Anacreon says, that through money there is no longer any such thing as brethren or parents in the world. 3. When the word which is used for a proper name, is either taken from the person's country, family, profession, personal circumstance, or resemblance to some other: thus, as Sardanapalus was a monster of debauchery, and Nero of cruelty, to call a very debauched person a Sardanapalus, and a cruel one Nero, brands them much deeper than to call one debauched, and the other cruel.

METOPE, in architecture, is the interval, or square space between the triglyphs of the doric frieze, which among the ancients used to be painted or adorned with carved work, representing the heads of oxen, or utensils used in sacrifices.

METOPOSCOPY, the pretended art of knowing a person's disposition and manners, by viewing the traces and lines in the face.

METRE, in poetry, a system of feet of a just length.

The different metres in poetry, are the different manners of ordering and combining the quantities, or the long and short syllables; thus hexameter, pentameter, iambic, sapphic verses, &c. consist of different metres, or measures.

In English verses, the metres are extremely various and arbitrary, every poet being at liberty to introduce any new form that he pleases. The most usual are the heroic, generally consisting of five long and five short syllables, and verses of four feet, and of three feet and a cæsuræ or single syllable.

METRETES, an ancient measure of capacity, containing a little more than nine gallons.

METROPOLIS, the capital or principal city of a country or province.

The term metropolis is also applied to archiepiscopal churches, and sometimes to the principal or mother church of a city.

METZ, a city of Germany, in the duchy of Lorrain, capital of the bishoprick of Metz, situated thirty miles north of Nancy.

MEXICO, the metropolis of New Spain at present, and formerly of the empire of Mexico, situated in W. long. 103°, N. lat. 20°.

This province of New Spain in America is now divided into Old and New Mexico.

Old Mexico, situated between 83 and 116 degrees of W. long. and between 8 and 28 degrees N. lat. is bounded by New Mexico, or Granada, on the north; by the gulph of Mexico, on the north-east; by Terra-firma, on the south-east; and by the Pacific Ocean, on the south-west.

New Mexico, including California, situated between 100 and 140 degrees of W. long. and between the Tropic of Cancer and 48 degrees of N. lat. is bounded by unknown lands on the north, by Florida on the east, by Old Mexico on the south, and by the Pacific Ocean on the west.

MEZZOTINTO, a particular manner of representing figures on copper, so as to form prints in imitation of painting in Indian ink.

The manner of making mezzotintos is very different from all other kinds of engraving and etching, since instead of forming the figures with lines and scratches made with the point of a graver, or by means of aquafortis, they are wholly formed by scraping and burnishing. Mezzotintos are made in the following manner: take a well-polished copper-plate, and beginning at the corner, rake or furrow the surface all over with a knife or instrument made for the purpose, first one way, and then the other, till the whole is of a regular roughness, without the last smooth part to be seen; in which state, if a paper was to be worked off from it at the copper-plate press, it would be all over black. When this is done, the plate is rubbed over with charcoal, black chalk, or black lead, and then the design is drawn with white chalk; after which the out-lines are traced

out,

out, and the plate finished by scraping off the roughness, so as to leave the figure on the plate. The outlines and deepest shades are not scraped at all, the next shades are scraped but little, the next more, and so on, till the shades gradually falling off, leave the paper white, in which the places the plate is nearly burnished.

By an artful disposition of the shades, and different parts of a figure on different plates, mezzotintos have been printed in colours, so as nearly to represent very beautiful paintings.

MIASMA, among physicians, denotes the contagious effluvia of pestilential diseases, whereby they are communicated to people at a distance.

MICA, **GLIMMER**, in natural history, a genus of tales.

The bright appearance of the gold and silver glimmers, has led some to imagine they were gold and silver ores; but the truth is, they contain not the least grain of either of these metals, being mere talc, accidentally coloured. See **TALC**.

MICAH, or the *book of MICAH*, a canonical book of the Old Testament, written by the prophet Micah, who is the seventh of the twelve lesser prophets. He is cited by Jeremiah, and prophesied in the days of Jotham, Ahaz, and Hezekiah. He censures the reigning vices of Jerusalem and Samaria, and denounces the judgments of God against both kingdoms. He likewise foretells the confusion of the enemies of the Jews, the coming of the Messiah, and the glorious success of his church.

MICHAELMAS, or *feast of St MICHAEL and all angels*, a festival of the Christian church, observed on the 29th of September.

MICHELIA, in botany, a genus of the polyandria polygynia class. The calix consists of eight segments, and the corolla of eight petals; and the berries contain many seeds. There is but one species, a native of India.

MICROCOS, in botany, a genus of the polyandria mo-

nogynia class. The calix consists of five leaves, and the corolla of five petals. There are two species, both natives of India.

MICROCOSM, a Greek term, signifying the little world; used by some for man, as being supposed an epitome of the universe or great world.

MICROGRAPHY, the description of objects too minute to be viewed without the assistance of a microscope. See **MICROSCOPE**.

MICROMETER, a machine, which, by means of a screw, serves to measure extremely small distances to a great degree of accuracy.

MICROPUS, in botany, a genus of the syngenesia polygamia segregata class. The receptacle is paleaceous; it has no pappus; and the corolla have no radii.

There are two species, none of them natives of Britain.

MICROSCOPE, an optical instrument, by means whereof very minute objects are represented. See **OPTICS**.

MIDAS-EAR-SHELL, the smooth ovato-oblong buccinum, with an oblong and very narrow mouth. It consists of six volutions, but the lower one alone makes up almost the whole shell.

MID-HEAVEN, the point of the ecliptic that culminates, or in which it cuts the meridian,

MIDDLEBURG, the capital city of Zealand, one of the United Provinces, situated in the island of Wulcherin, twenty-six miles north-east of Bruges.

MIDDLESEX, a county of England, in which London, the metropolis, stands. It is twenty four miles long, and only fourteen broad; and is bounded by Hertfordshire, on the north; by the river Lea, which divides it from Essex, on the east; by the river Thames, which separates it from Surry, on the south; and by the brook Coln, which divides it from Buckinghamshire, on the west.

MIDHURST, a borough-town of Suffex, ten miles north of Chichester; which sends two members to parliament.

M I D W I F E R Y.

MIDWIFERY is the art of assisting nature in bringing forth a perfect fœtus, or child, from the womb of the mother.

The knowledge of this art depends greatly on an intimate acquaintance with the anatomy of the parts of generation in women, both internal and external. But, as those have already been fully described under the article **ANATOMY**, we must refer to the different parts of that science upon which the knowledge of midwifery depends.

For the **BONES** of the **PÆLVIS**, see **ANATOMY**, p. 171, &c.

For the **PARTS** of **GENERATION** in **FEMALES**, both external and internal, see **ANATOMY**, p. 274, &c.

For the different theories of **CONCEPTION**, see **GENERATION**.

Of the increase of the UTERUS after conception.

It is supposed, that the ovum swims in a fluid, which

VOL. III. N^o. 77.

2

it absorbs so as to increase gradually in magnitude, till it comes in contact with all the inner surface of the fundus uteri; and this being distended in proportion to the augmentation of its contents, the upper part of the neck begins also to be stretched.

About the third month of gestation, the ovum in bigness equals a goose egg; and then nearly one fourth of the neck, at its upper part, is distended equal with the fundus. At the fifth month, the fundus is increased to a much greater magnitude, and rises upwards to the middle space betwixt the upper part of the pubes and the navel; and at that period, one half of the neck is extended. At the seventh month, the fundus reaches as high as the navel; at the eighth month, it is advanced midway between the navel and *scrobiculus cordis*; and in the ninth month, is raised quite up to this last mentioned part, the neck of the womb being then altogether distended. See Plate CXI. fig. 1, 2, 3.

3 F

†

FIG. 1

FIG. 1. Gives a front-view of the uterus *in situ* suspended in the vagina; the anterior parts of ossa ilchium, with the ossa pubis, pudenda, perinæum, and anus, being removed in order to shew the internal parts.

- A, The last vertebra of the loins.
- BB, The ossa ilium.
- CC, The acetabula.
- DD, The inferior and posterior parts of the ossa ilchium.
- E, The part covering the extremity of the coccyx.
- F, The inferior part of the rectum.
- GG, The vagina cut open longitudinally, and stretched on each side of the collum uteri, to shew in what manner the uterus is suspended in the same.
- HH, Part of the vesica urinaria stretched on each side of the vagina, and inferior part of the fundus uteri.
- I, The collum uteri.
- K, The fundus uteri.
- LL, The tubi Fallopiiani and fimbriæ.
- MM, The ovaria.
- NN, The ligamenta lata and rotunda.
- OO, The superior part of the rectum.

FIG. 2. Gives a front-view of the uterus in the beginning of the first month of pregnancy; the anterior part being removed that the embryo might appear through the amnios, the chorion being dissected off.

- A, The fundus uteri.
- B, The collum uteri, with a view of the rugous canal that leads to the cavity of the fundus.
- C, The os uteri.

FIG. 3. In the same view and section of the parts as in fig. 1. shews the uterus as it appears in the second or third month of pregnancy.

- F, The anus.
- G, The vagina, with its plicæ.
- HH, The posterior and inferior part of the urinary bladder extended on each side; the anterior and superior part being removed.
- II, The mouth and neck of the womb, as raised up when examining the same by the touch, with one of the fingers in the vagina.
- KK, The uterus as stretched in the second or third month, containing the embryo, with the placenta adhering to the fundus.

Now that the whole substance of the uterus is stretched, the neck and os internum, which were at first the strongest, become the weakest part of the womb, and the stretching force being still continued by the increase of the fœtus and secundines, which are extended by the inclosed waters in a globular form, the os uteri begins gradually to give way. In the beginning of its dilatation, the nervous fibres in this place, being more sensible than any other part of the uterus, are irritated, and yield an uneasy sensation; to alleviate which, the woman squeezes her uterus, by contracting the abdominal muscles, and at the same time filling the lungs with air, by which the diaphragm is kept down; the pain being rather increased than abated by this straining, is communicated to all the neighbouring parts, to which the ligaments and vessels are

attached, such as the back, loins, and inside of the thighs; and by this compression of the uterus, the waters and membranes are squeezed against the os uteri, which is, of consequence, a little more opened. See fig. 4, 5, 6. of Plate CXI.

FIG. 4. In the same view and section of the parts with the former figures, represents the uterus in the eighth or ninth month of pregnancy.

- A, The uterus as stretched to near its full extent, with the waters, and containing the fœtus entangled in the funis, the head presenting at the upper part of the pelvis.
- BB, The superior part of the ossa ilium.
- CC, The acetabula.
- DD, The remaining posterior parts of the ossa ilchium.
- E, The coccyx.
- F, The inferior part of the rectum.
- GGG, The vagina stretched on each side.
- H, The os uteri, the neck being stretched to its full extent or entirely obliterated.
- II, Part of the vesica urinaria.
- KK, The placenta, at the superior and posterior part of the uterus.
- LL, The membranes.
- M, The funis umbilicalis.

FIG. 5. Gives a front view of twins *in utero* in the beginning of labour.

- A, The uterus as stretched, with the membranes and waters.
- BB, The superior parts of the ossa ilium.
- CC, The acetabula.
- DD, The ossa ilchium.
- E, The coccyx.
- F, The lower part of the rectum.
- GG, The vagina.
- H, The os internum stretched open about a finger-breadth, with the membranes and waters in time of labour-pains.
- II, The inferior part of the uterus, stretched with the waters, which are below the head of the child that presents.
- KK, The two placentas adhering to the posterior part of the uterus, the two fœtus's lying before them, one with its head in a proper position at the inferior part of the uterus, and the other situated preternaturally with the head to the fundus: the bodies of each are here entangled in their proper funis, which frequently happens in the natural as well as preternatural positions.

LLL, The membranes belonging to each placenta.

FIG. 6. Shews, in a lateral view and longitudinal division of the parts, the gravid uterus when labour is somewhat advanced.

- A, The lowest vertebra of the back; the distance from which to the last mentioned vertebra is here shewn by dotted lines.
- CC, The usual thickness and figure of the uterus when extended by the waters at the latter end of pregnancy.

Fig. 6.

D, The fame contracted and grown thicker after the waters are evacuated.

EE, The figure of the uterus when pendulous.

FF, The figure of the uterus when stretched higher than usual, which generally occasions vomitings and difficulty of breathing.

G, The os pubis of the left side.

HH, The os internum.

I, The vagina.

K, The left nympha.

L, The labium pudendi of the same side.

M, The remaining portion of the bladder.

N, The anus.

OP, The left hip and thigh.

The woman being unable to continue this effort, for any length of time, from the violence of the pain it occasions, and the strength of the muscles being thereby a little exhausted and impaired, the contracting force abates; the tension of the os *unicæ* being taken off, it becomes more soft, and contracts a little; so that the nervous fibres are relaxed. This remission of pain the patient enjoys for some time, until the same increasing force renews the stretching pains, irritation, and something like a tenesmus at the os uteri; the compression of the womb again takes place, and the internal mouth is a little more dilated, either by the pressure of the waters and membranes, or when the fluid is in small quantity, by the child's head forced down by the contraction of the uterus, which in that case is in contact with the body of the fœtus. See Plate CXL. where

FIG. 7. Shews the forehead of the fœtus turned backwards to the os sacrum, and the occiput below the pubes, by which means the narrow part of the head is to the narrow part of the pelvis, that is, between the inferior parts of the ossa ischia.

A, The uterus contracted closely to the fœtus after the waters are evacuated.

BCD, The vertebrae of the loins, os sacrum, and coccyx.

E, The anus.

F, The left hip.

G, The perineum.

H, The os externum beginning to dilate.

I, The os pubis of the left side.

K, The remaining portion of the bladder.

L, The posterior part of the os uteri.

In this manner the labour pains begin, and continue to return periodically, growing stronger and more frequent, until the os uteri is fully dilated, and the membranes are depressed and broke; so that the waters are discharged, the uterus contracts, and, with the assistance of the muscles, the child is forced along and delivered.

OF ABORTIONS.

A MISCARRIAGE that happens before the tenth day, was formerly called an efflux, because the embryo and secundines are not then formed, and nothing but the liquid conception, or genitura, is discharged. From the tenth day to the third month it was known by the term expulsion, the embryo and secundines being still so small,

that the woman is in no great danger from violent flooding.

If she parted with her burden betwixt that period and the seventh month, she was said to suffer an abortion; in which case she underwent greater danger, and was delivered with more difficulty than before; because the uterus and vessels being more distended, a larger quantity of blood was lost in a shorter time, the fœtus was increased in bulk, and the neck of the womb is not yet fully stretched: besides, should the child be born alive, it will be so small and tender that it will not suck, and scarce receive any sort of nourishment.

When delivery happens between the seventh month and full time, the woman is said to be in labour: but, instead of these distinctions, if she loses her burden at any time from conception to the seventh or eighth, or even in the ninth month, we now say indiscriminately, she has miscarried.

The common term of pregnancy is limited to nine solar months, reckoning from the last discharge of the catamenia: yet in some, though very few, uterine gestation exceeds that period.

Of false CONCEPTIONS and MOLDS.

It was formerly supposed, that if the parts of the embryo and secundines were not separated and distinctly formed from the mixture of the male and female semen, they formed a mass, which, when discharged before the fourth month, was called a false conception; if it continued longer in the uterus, so as to increase in magnitude, it went under the denomination of a *mola*. But these things are now to be accounted for in a more probable and certain manner. Should the embryo die (suppose in the first or second month,) some days before it is discharged, it will sometimes be entirely dissolved; so that, when the secundines are delivered, there is nothing else to be seen. In the first month, the embryo is so small and tender, that this dissolution will be performed in twelve hours; in the second month, two, three, or four days will suffice for this purpose; and even in the third month, it will be dissolved in fourteen or fifteen: besides the blood frequently forms thick laminae round the ovum, to the surface of which they adhere so strongly, that it is very difficult to distinguish what part is placenta, and what membrane. Even after the embryo and placenta are discharged, in the second or third month, the mouth and neck of the womb are often so closely contracted, that the stertuous part of the blood is retained in the fundus, sometimes to the fifth or seventh day; and when it comes off, exhibits the appearance of an ovum, the external surface, by the strong pressure of the uterus, resembling a membrane; so that the whole is mistaken for a false conception.

This substance, in bigness, commonly equals a pigeon or hen egg; or if it exceeds that size, and is longer retained, is distinguished by the appellation of *mola*: but this last generally happens in women betwixt the age of forty-five and sixty, or later, when their menses begin to disappear; sometimes from internal or external accidents that may produce continued floodings. If the catamenia

have ceased to flow for some time in elderly women, and return with pain, such a symptom is frequently the forerunner of a cancer; before or after this happens, sometimes a large flesh-like substance will be discharged with great pain, resembling that of labour; and upon examination, appears to be no more than the fibrous part of the blood, which assumes that form by being long pressed in the uterus or vagina.

In this place, it will not be amiss to observe, that the glands of the uterus and vagina will sometimes increase, and distend the adjacent parts to a surprising degree; if (for example) one of the glands of the uterus be so obstructed as that there is a pressure on the returning vein and excretory duct, the arterial blood will gradually stretch the smaller vessels, and consequently increase the size of the gland, which will grow larger and larger, as long as the force of the impelled fluid is greater than the resistance of the vessels that contain it; by which means, a very small gland will be enlarged to a great bulk, and the uterus gradually stretched as in uterine gestation, though the progress may be so slow as to be protracted for years instead of months. Nevertheless, the os internum will be dilated, and the gland (if not too large to pass) will be squeezed into the vagina, provided it adheres to the uterus, by a small neck; nay, it will lengthen more and more, so as to appear on the outside of the os externum; in which case, it may be easily separated by a ligature. This disease will be the sooner known and easier remedied, the lower its origin in the uterus is. But should the gland take its rise in the vagina, hard by the mouth of the womb, it will shew itself still sooner, and a ligature may be easily introduced, provided the tumour is not so large as to fill up the cavity and hinder the neck of it from being commodiously felt. Though the greatest difficulty occurs, when the gland is confined to the uterus, being too much enlarged to pass through the os internum.

Sometimes all, or most of the glands in the uterus, are thus affected, and augment the womb to such a degree, that it will weigh a great many pounds, and the woman is destroyed by its pressure upon the surrounding parts: but, should this indolent state of the tumour be altered by any accident that will produce irritation and inflammation, the parts will grow scirrhous, and a cancer ensue.

This misfortune, for the most part, happens to women, when their menstrual evacuations leave them; and sometimes (though seldom) to child bearing women, in consequence of severe labour.

Of the PLACENTA.

THE OVUM is formed of the placenta with the chorion and amnion, which are globularly distended by the included waters that surround the child. The placenta is commonly of a round figure, somewhat resembling an oat-cake, about six inches in diameter, and one inch thick in the middle, growing a little thinner towards the circumference: it is composed of veins and arteries, which are divided into an infinite number of small branches, the venous parts of which unite in one large tube, called the umbilical vein, which brings back the blood, and is supposed to carry along the nutritive fluid from the vessels of the chorion and placenta, to the child, whose belly it

perforates at the navel; from thence passing into the liver, where it communicates with the vena portarum and cava. It is furnished with two arteries, which arise from the internal iliacs of the child, and running up on each side of the bladder, perforates the belly where the umbilical vein entered; then they proceed to the placenta, in a spiral line, twining round the vein, in conjunction with which they form the funiculus umbilicalis, which is commonly four or five hand breadths in length, sometimes only two or three, and sometimes it extends to the length of eight or ten. The two arteries, on their arrival at the inner surface of the placenta, are divided and subdivided into minute branches, which at last end in small capillaries that inosculate with the veins of the same order. These arteries, together with the umbilical vein, are supposed to do the same office in the placenta which is afterwards performed in the lungs by the pulmonary artery and vein, until the child is delivered and begins to breathe: and this opinion seems to be confirmed by the following experiments. If the child and placenta are both delivered suddenly, or the last immediately after the first; and if the child, though alive, does not yet breathe; the blood may be felt circulating, sometimes slowly, at other times with great force, through the arteries of the funis to the placenta, and from thence back again to the child, along the umbilical vein. When the vessels are slightly pressed, the arteries swell between the pressure and the child, while the vein grows turgid between that and the placenta, from the surface of which no blood is observed to flow, although it be lying in a basin, among warm water. As the child begins to breathe, the circulation, though it was weak before, immediately grows stronger and stronger, and then in a few minutes the pulsation in the navel-string becomes more languid, and at last entirely stops. If, after the child is delivered, and the navel string cut, provided the placenta adheres firmly to the uterus, which is thereby kept extended; or, if the womb is still distended by another child; no more blood flows from the umbilical vessels, than what seemed to be contained in them at the instant of cutting; and this, in common cases, does not exceed the quantity of two or three ounces; and finally, when, in consequence of violent floodings, the mother expires, either in time of delivery, or soon after it, the child is sometimes found alive and vigorous, especially if the placenta is found; but if tore, then the child will lose blood as well as the mother.

The external surface of the placenta is divided into several lobes, that it may yield and conform itself more commodiously to the inner surface of the uterus, to which it adheres, so as to prevent its being separated by any shock or blows upon the abdomen, unless when violent.

Those groups of veins and arteries which enter into the composition of the placenta receive external coats from the chorion, which is the outward membrane of the ovum, thick and strong, and forms three fourths of the external globe that contains the waters and the child; the remaining part being covered by the placenta; so that these two in conjunction constitute the whole external surface of the ovum. Some indeed alledge, that these are enveloped with a cribriform or cellular substance, by which

which they seem to adhere by contact only, to the uterus; and that the inner membrane of the womb is full of little glands, whose excretory ducts opening into the fundus and neck, secrete a soft thin mucus, to lubricate the whole cavity of the uterus, which beginning to stretch in time of gestation, the vessels that compose these glands are also distended; consequently, a greater quantity of this mucus is separated and retained in this cribriform and cellular substance, the absorbing vessels of which take it in, and convey it along the veins, for the nourishment of the child. The womb being therefore distended in proportion to the increase of the child, those glands are also proportionably enlarged; by which means, a larger quantity of the fluid is separated, because the nutriment of the child must be augmented in proportion to the progress of its growth; and this liquor undergoes an alteration in quality as well as in quantity, being changed from a clear thin fluid into the more viscous consistence of milk. In some cases this mucus hath been discharged from the uterus in time of pregnancy, and both mother and child weakened by the evacuation, which may be occasioned by the chorion's adhering too loosely, or being in one part actually separated from the womb.

Formerly, it was taken for granted by many, that the placenta always adhered to the fundus uteri; but this notion is refuted by certain observations, in consequence of which we find it as often sticking to the sides, back and fore parts, and sometimes as far down as the inside of the os uteri. See Plate CXI.

When the placenta is delivered, and no other part of the membrane tore except that through which the child passed, the opening is near the edge or side of the placenta, and seldom in the middle of the membranes; and a hog's bladder being introduced at this opening, and inflated, when lying in water, will shew the shape and size of the inner surface of the womb, and plainly discover the part to which the placenta adhered.

The chorion is, on the inside, lined with the amnion, which is a thin transparent membrane, without any vessels so large as to admit the red globules of blood; it adheres to the chorion by contact, and seems to form the external coat of the funis umbilicalis.

This membrane contains the serum, in which the child swims: which fluid is supposed to be furnished by lymphatic vessels that open into the inner surface of the amnion. If this liquid is neither absorbed into the body of the fœtus, nor taken into the stomach by suction at the mouth, there must be absorbing vessels in this membrane, in the same manner as in the abdomen and other cavities of the body, where there is a constant renovation of humidity.

The quantity of this fluid, in proportion to the weight of the fœtus, is much greater in the first than in the last month of gestation, being in the one perhaps ten times the weight of the embryo; whereas, in the other, it is commonly in the proportion of one to two: for, six pounds of water surrounding a fœtus that weighs twelve pounds, is reckoned a large proportion, the quantity being often much less; nay, sometimes there is very little or none at all.

In most animals of the brute species, there is a third membrane called allantois, which resembles a long and

wide blind-gut, and contains the urine of the fœtus: it is situated between the chorion and amnion, and communicates with the urachus that rises from the fundus of the bladder, and runs along with the umbilical vessels, depositing the urine in this reservoir, which is attached to its other extremity. This bag hath not yet been certainly discovered in the human fœtus, the urachus of which, though plainly perceivable, seems hitherto to be quite imperforated.

From the foregoing observations upon nutrition, it seems probable, that the fœtus is rather nourished by the absorption of the nutritive fluid into the vessels of the placenta and chorion, than from the red blood circulated in full stream from the arteries of the uterus to the veins of the placenta, and returned by the arteries of the last to the veins of the first, in order to be renewed, refined, and made arterial blood in the lungs of the mother.

Of the CHILD's situation in the UTERUS.

THE embryo or fœtus, as it lies in the uterus, is nearly of a circular or rather oval figure, which is calculated to take up as little space as possible: the chin rests upon the breasts, the thighs are pressed along the belly, the heels applied to the breech, the face being placed between the knees, while the arms cross each other round the legs. The head, for the most part, is down to the lower part of the uterus; and the child being contracted into an oval form, the greatest length is from head to breech: but the distance from one side to the other is much less than that from the fore to the back part; because the thighs and legs are doubled along the belly and stomach, and the head bended forwards on the breast. The uterus being confined by the vertebræ of the loins, the distance from the back to the fore-part of it must be less than from side to side; so that, in all probability, one side of the fœtus is turned towards the back, and the other to the fore-part of the womb: but, as the back part of the uterus forms a little longish cavity on each side of the vertebræ, the fore-parts of the fœtus may therefore for the most part tilt more backwards than forwards.

It has been generally supposed, that the head is turned up to the fundus, and the breech to the os uteri, with the fore-parts towards the mother's belly; and that it remains in this situation till labour begins, when the head comes downwards, and the face is turned to the back of the mother. Some alledge, that the head precipitates about the end of the eighth or beginning of the ninth month, by becoming specifically heavier than the rest of the body. Others affirm, that as the child increases in bulk, especially during the two last months, the proportion of surrounding water must be diminished, so as that it is confined in its motion, and, in struggling to alter its position, the head is moved to the os tunicæ, where it remains till delivery. The particulars of this and other theories may be found in *Mauriceau, Le Motte, Simpson, and Old*. But, from the following observations, it seems more probable, that the head is, for the most part, turned down to the lower part of the uterus from conception to delivery.

In the first month, according to some writers, the em-
3 G † bryo

bryo exhibits the figure of a tadpole, with a large head and small body or tail, which gradually increases in magnitude, till the arms and thighs begin to bud or strut out, like small nipples, from the shoulders and breech: two black specks appear on each side of the head, with a little hole or opening between them, which in the second month are easily distinguished to be the eyes and mouth. See Plate CXI. fig. 2. The legs and arms are gradually formed, while the body turns larger; but the fingers are not separated or distinct, till the latter end of the second or beginning of the third month. See Plate CXI. fig. 3. This is commonly the case; but sometimes the bulk and appearance differ considerably in different embryos of the same age. The younger the embryo, the larger and heavier is the head in proportion to the rest of the body; and this is the case in all the different gradations of the fœtus; so that when dropt or suspended by the navel string in water, the head must sink lowermost of course. Besides, when women miscarry in the fourth, fifth, sixth, and seventh months, the head for the most part presents itself, and is first delivered. See Plate CXI. fig. 3. By the touch in the vagina, the head is frequently felt in the fourth, sometimes in the sixth, but more frequently in the eighth month; and if the same women are thus examined, from time to time, till the labour begins, the head will always be felt of a round firm substance at the fore-part of the brim of the pelvis, betwixt the os internum and pubes, through the substance of the vagina and uterus. See Plate CXI. fig. 4. But all those opinions are liable to objections. If the descent of the head proceeded from its specific gravity, we would always find it at the os internum, because this reason would always prevail; if it were owing to a diminished proportion of water, why should we often find the breech presented, even when there is a quantity of that fluid large enough to give the head free liberty to rise again towards the fundus, or (according to the other opinion) to sink down by its specific gravity to the os internum? Some, indeed, suppose, that the head always presents itself, except when it is hindered by the funis umbilicalis twisting round the neck and body, so as to impede the natural progress: but, were this supposition just, when we turn and deliver by the feet those children that presented in a preternatural way, we should always find them more or less circumvolved by the navel-string: the funis is as often found twisted round the neck and body when the head presents as in any other case. That the head is downwards all the time of gestation, seems, on the whole, to be the most reasonable opinion, though it be liable to the objection already mentioned, and seems contradictory to the observation of some authors, who allege, that in opening women that died in the fifth, sixth, or seventh month, they have found the child's head towards the fundus uteri. But as it lies as easy in one posture as in another, till the birth, this dispute is of less consequence in the practice of midwifery. It may be useful to suggest, that the wrong posture of the child in the uterus may proceed,

1. From circumvolutions in the funis umbilicalis. See Plate CXIII. fig. 1. which represents, in a front view of the pelvis, the breech of the fœtus presenting, and dila-

ting the os internum, the membranes being too soon broke. The fore-parts of the child are to the posterior part of the uterus; and the funis, with a knot upon it, surrounds the neck, arms, and body.

Or, 2. When there is little or no water surrounding the child, it may move into a wrong position, and be confined there by the stricture of the uterus. See Plate CXIII. fig. 2, 3, 4.

FIG. 2. is the reverse of fig. 1. the fore-parts of the child being to the fore-part of the uterus.

FIG. 3. represents, in a front view of the pelvis, the fœtus compressed, by the contraction of the uterus, into a round form, the fore-parts of the former being towards the inferior part of the latter, and one foot and hand fallen down into the vagina. In this figure, the anterior part of the pelvis is removed, by a longitudinal section through the middle of the foramen magnum.

AA, The superior parts of the ossa ilium.

BB, The uterus.

C, The mouth of the womb stretched and appearing in OOOO, The vagina.

D, The inferior and posterior part of the os externum.

EEEE, The remaining parts of the ossa pubis and ischium.

FFFF, The membrana adiposa.

FIG. 4. represents, in the same view with fig. 3. the fœtus in the contrary position; the breech and fore-parts being towards the fundus uteri, the left arm in the vagina, and the fore arm without the os externum, the shoulder being likewise forced into the os uteri.

Or, lastly, The wrong position of the child may be the effect of a pendulous belly or narrow pelvis, when the head lies forward over the pubis. See Plate CXI. fig. 6. See also Plate CXII. fig. 6. and 7.

FIG. 6. gives a lateral internal view of a distorted pelvis, divided longitudinally, with the head of a fœtus of the seventh month passing the same.

ABC, The os sacrum and coccyx.

D, The os pubis of the left side.

E, The tuberosity of the os ischium of the same side.

FIG. 7. gives a side view of a distorted pelvis, divided longitudinally, with the head of a full grown fœtus squeezed into the brim, the parietal bones decussating each other, and compressed into a conical form.

ABC, The os sacrum and coccyx.

D, The os pubis of the left side.

E, The tuberosity of the os ischium.

F, The processus acutus.

G, The foramen magnum.

OF TOUCHING.

Touching is performed by introducing the fore-finger lubricated with pomatum into the vagina, in order to feel the os internum and neck of the uterus; and sometimes into the rectum, to discover the stretching of the fundus. By some, we are advised to touch with the middle finger, as being the longest; and by others, to employ both that and the first: but the middle is too much encumbered by that on each side, to answer the purpose fully.

fully; and when two are introduced together, the patient never fails to complain. The design of touching is to be informed whether the woman is, or is not with child; to know how far she is advanced in her pregnancy; if she is in danger of a miscarriage; if the os uteri be dilated; and in time of labour to form a right judgment of the case, from the opening of the os internum, and the pressing down of the membranes with their waters; and lastly, to distinguish what part of the child is presented.

It is generally impracticable to discover, by a touch in the vagina, whether or not the uterus is impregnated, till after the fourth month: then the best time for examination is the morning, when the woman is fasting, after the contents of the bladder and rectum have been discharged; and she ought, if necessary, to submit to the inquiry in a standing posture; because, in that case, the uterus hangs lower down in the vagina, and the weight is more sensible to the touch than when she lies reclined. One principal reason of our uncertainty is, when we try to feel the neck, the womb rises up on our pressing against the vagina, at the side of the os internum, (see Plate CXI. fig. 3.) and in some, the vagina feels very tense; but, when the fundus uteri is advanced near the navel, the pressure from above keeps down the os internum so much, that you can generally feel both the neck, and, above that, the stretching of the under part of the uterus. See Plate. CXI. fig. 3.

There is no considerable variation to be felt in the figure of the os internum, except in the latter end of pregnancy, when it sometimes grows larger and softer, (see Plate CXI. fig. 4.) nor do the lips seem to be more closed in a woman with child than in another, especially in the beginning of pregnancy: but, in both cases the os uteri is felt like the mouth of a young puppy or tench. In some the lips are very small; in others, large; and sometimes, though seldom, smoothed over or pointed. In many women, who have formerly had children and difficult labours, the lips are large, and so much separated, as to admit the tip of an ordinary finger; but a little higher up, the neck seems to be quite closed.

In the first four months, the neck of the womb may be felt hanging down in the vagina, by pushing up the finger by the side of the os internum; but the stretching of the uterus and upper part of the neck cannot be perceived till the fifth, and sometimes the sixth month; and even then, the uterus must be kept down by a strong pressure upon the belly.

The stretching of the fundus is sometimes felt by the finger introduced into the rectum, before it can be perceived in the vagina; because, in this last method, the uterus recedes from the touch, and rises too high to be accurately distinguished; whereas the finger being introduced into the rectum, passes along the back of the womb almost to the upper part of the fundus, which, in an unimpregnated state, is felt flat on the back part and jetting out at the sides; but the impregnated uterus is perceived like a large round tumour.

About the fifth or sixth month, the upper part of the uterus is so much stretched, as to rise three or four inches above the os pubis, or to the middle space between that and the navel; so that, by pressing the hand on the

belly, especially of lean women, it is frequently perceived; and if, at the same time, the index of the other hand be introduced in the vagina, the neck will seem shortened, particularly at the fore-part and sides, and the weight will be sensibly felt; but, if the parietes of the abdomen are stretched after eating, one may be deceived by the pressure of the stomach, because weight and pressure are the same. But all these signs are more perceptible towards the latter end of pregnancy; and in some women the os internum is felt a little open some weeks before the full time, though generally it is not opened till a few days before labour begins.

From the fifth to the ninth month, the neck of the uterus becomes shorter and shorter, and the stretching of the womb grows more and more perceptible. In the seventh month, the fundus rises as high as the navel; in the eighth month, to the middle space betwixt the navel and scrobiculus cordis; and in the ninth, even to the scrobiculus, except in pendulous bellies: See Plate CXI. fig. 4. But all these marks may vary in different women: for when the belly is pendulous, the parts below the navel are much more stretched than those above, and hang over the os pubis; the fundus will then be only equal to, or a little higher than the navel; at other times, the uterus will rise in the latter end of the seventh or eighth month to the scrobiculus cordis. The neck of the womb will, in some, be felt as long in the eighth, as in others in the sixth or seventh month. This variation sometimes makes the examination of the abdomen more certain than the touch of the vagina; and so *vice versa*. At other times we must judge by both. See Plate CXI. fig. 6.

Of the signs of CONCEPTION, and the equivocal signs of pregnant and obstructed women.

THE signs of pregnancy are to be distinguished from those that belong to obstructions, by the touch in the vagina and motion of the child, in the fifth or sixth month; sometimes, by the touch in the rectum, before and after the fifth month, when the tumour of the abdomen is plainly perceived.

Most women, a day or two before the irruption of the catamenia, labour under complaints proceeding from a plethora; such as stretching pains in the back and loins, inside of the thighs, breast and head; a sickness and oppression at the stomach, and a fullness of all the viscera of the abdomen; and all these symptoms abate, and gradually vanish, when the discharge begins and continues to flow. But, if the woman be obstructed by any accident or error in the non-naturals, all those complaints continue and increase, and are hardly distinguishable from the symptoms of pregnancy, till the end of the fourth month; at which period, women with child grow better, and all the complaints of fullness gradually wear off, whereas, those who are only obstructed, grow worse and worse. The fundus uteri, in the obstructed patient, is not stretched; the disorder in the stomach is not so violent as in a pregnant woman, and seldom accompanied with reachings; while the women with child is afflicted with a reaching every morning, and subject to longings besides. The first labours under a fullness of the vessels; the last, over and above this complaint, suffers an additional one from the

the distension of the uterus by the impregnated ovum. Obstructions and pregnancy are both accompanied by a stretching fullness in the breasts; but in the last only, may be perceived the areola, or brown ring, round the nipples, from which, in the last months, a thin serum distils; but this circle is not always so discernible as in the first pregnancy, and even then is uncertain as well as the others.

About the fifth or sixth month, the circumscribed tumour or stretching of the uterus is felt above the os pubis; and, by this circumscription and confidence, easily distinguished from the ascites, or dropsy of the abdomen: it is also rounder and firmer than those swellings that accompany obstructions, which proceed from a general fullness of the vessels belonging to the ligaments and neighbouring viscera.

On the whole, the difficulty of distinguishing between obstructions and pregnancy in the first months, is so great, that we ought to be cautious in giving our opinion; and never prescribe such remedies as may endanger the fruit of the womb; but rather endeavour to palliate the complaints, until time shall discover the nature of the case; and always judge on the charitable side, when life or reputation is at stake.

In the fifth or sixth month of uterine gestation, by the touch in the vagina, we perceive the neck of the womb considerably shortened, and the stretching of the lower part of the uterus is then sensibly felt between the mouth of the womb and the pubes, and on each side of the neck. See Plate CXI. fig. 3.

In the seventh month, the head of the child is frequently felt resting against the lower part of the uterus, between the pubes and os internum; and being pushed upwards towards the fundus, sinks down again by its own gravity. All these diagnostics are more plain and certain, the nearer the patient approaches to the time of delivery.

Sometimes, the head is not felt till the eighth or ninth month; and in some few cases, not till after the membranes are broke, when it is forced down by the contraction of the uterus, and strong labour-pains. This circumstance may be owing to the head's resting above the basin, especially in a narrow pelvis; or to the distension of its belly with air after death, by which the fœtus being rendered specifically lighter than the surrounding waters, the body floats up to the fundus, if there is a large quantity of fluid in the membranes; nor is the body always felt when the child lies across the uterus.

How to distinguish the false Labour from the true, and the means to be used on that occasion.

If the os uteri remains close shut, it may be taken for granted that the woman is not yet in labour, notwithstanding the pains she may suffer: with regard to which, an accurate inquiry is to be made; and if her complaints proceed from an over stretching fullness of the uterus or vessels belonging to the neighbouring parts, bleeding in the arm or ankle, to the quantity of six or eight ounces, ought to be prescribed, and repeated occasionally. If the pains are occasioned by a looseness or diarrhœa, it must be immediately restrained with opiates. Cholic pains are

distinguished from those of labour, by being chiefly confined to the belly, without going off and returning by distinct intervals: they are for the most part produced by feces too long retained in the colon, or by such ingesta as occasion a rarefaction or expansion of air in the intestines; by which they are violently stretched and vellicated. This complaint must be removed by opening glysters, to empty the guts of their noxious contents: and this evacuation being performed, opiates may be administered to allay the pains; either to be injected by the anus, taken by the mouth, or applied externally in form of epithem or embrocation.

Sometimes, the os internum may be a little dilated, and yet it may be difficult to judge whether or not the patient be in labour; the case, however, may be ascertained, after some attendance, by these considerations: if the woman is not arrived at her full time; if no soft or glary mucus hath been discharged from the vagina; if the pains are limited to the region of the belly, without extending to the back and inside of the thighs; if they are slight, and continue without intermission or increase; nay, if they have long intervals, and recur without force sufficient to push down the waters and membranes, or child's head, to open the os internum; if this part be felt thick and rigid, instead of being soft, thin, and yielding; we may safely pronounce, that labour is not yet begun; and those alarms are to be removed as we have directed in the case of false or cholic pains. Besides, if the pulse be quick and strong, and the patient attacked by stitches in the sides, back, or head, bleeding will be likewise necessary. See Plate CXI, fig. 4.

The division of LABOURS.

A NATURAL labour is when the head presents, and the woman is delivered by her pains and the assistance commonly given: but, should the case be so tedious and lingering, that we are obliged to use extraordinary force, in stretching the parts, extracting with the forceps, or (to save the mother's life) in opening the head and delivering with the crotchet, it is distinguished by the appellation of *laborious*: and the *preternatural* comprehends all those cases in which the child is brought by the feet, or the body delivered before the head. Neither do we mind how the child presents, so much as the way in which it is delivered: for there are cases in which the head presents, and for several hours we expect the child will be delivered in the natural way; but if the woman has not strength enough to force down the child's head into the pelvis, or in floodings, we are at length obliged to turn and bring it by the feet, because it is so high that the forceps cannot be applied; and if the child is not large, nor the pelvis narrow, it were pity to destroy the hopes of the parents, by opening the skull and extracting with the crotchet. In this case, therefore, although the child presents in a natural way, we are obliged to turn and deliver it in the same manner as if the shoulder, breast, or back, had presented; and generally, this operation is more difficult than in either of those cases, because, if the waters are all discharged, and the uterus close contracted round the fœtus, it is more difficult to raise the head to the fundus. When the breech presents, we are frequently

ly obliged to push it up, and search for the legs; which being found, we proceed to deliver the body, and lastly the head. If the head is large, or the pelvis narrow, and the waters not discharged, we ought, if possible, to turn the child into the natural position.

For a further illustration, and to inform young practitioners that difficult cases do not frequently occur, suppose, of three thousand women in one town or village, one thousand shall be delivered in the space of one year, and in nine hundred and ninety of these births, the child shall be born without any other than common assistance: fifty children of this number shall offer with the forehead turned to one side, at the lower part of the pelvis, where it will stop for some time; ten shall come with the forehead towards the groin, or middle of the pubes; five shall present with the breech, two or three with the face, and one or two with the ear; yet, all these shall be safely delivered, and the case be more or less lingering and laborious, according to the size of the pelvis and child, or strength of the woman: of the remaining ten that make up the thousand, six shall present with the head differently turned, and two with the breech; and these cannot be saved without stretching the parts, using the forceps or crotchet, or pushing up the child in order to bring it by the feet; this necessity proceeding either from the weakness of the woman, the rigidity of the parts, a narrow pelvis, or a large child, &c. the other two should lie across, and neither head nor breech, but some other part of the body, present, so that the child must be turned and delivered by the feet. Next year, let us suppose another thousand women delivered in the same place; not above three, six, or eight, shall want extraordinary assistance; nay, sometimes, though seldom, when the child is young, or unusually small, and the mother has strong pains and a large pelvis, it shall be delivered even in the very worst position, without any other help than that of the labour-pains.

As the head, therefore, presents right in nine hundred and twenty of a thousand labours, all such are to be accounted natural; those of the other seventy, that require assistance, may be deemed laborious; and the other ten to be denominated laborious or preternatural, as they are delivered by the head or feet.

In order therefore to render this treatise as distinct as possible, for the sake of the reader's memory, as well as of the dependance and connection of the different labours, they are divided in the following manner: that is accounted natural, in which the head presents, and the woman is delivered without extraordinary help; those births are called laborious or nonnatural, when the head comes along with difficulty, and must be assisted either with the hand in opening the parts, or with the fillet or forceps, or even when there is a necessity for opening and extracting it with the crotchet; and those in which the child is brought by the breech or feet, are denominated preternatural, because the delivery is performed in a preternatural way.

Of the different positions of women in labour.

In almost all countries, the woman is allowed either to sit, walk about, or rest upon a bed, until the os uteri

is pretty much dilated by the graduation of the waters, or (when they are in small quantity) by the head of the fœtus, so that delivery is soon expected; when she is put in such position as is judged more safe, easy, and convenient for that purpose: but the patient may be put upon labour too prematurely, and bad consequences will attend such mistakes.

Among the *Egyptians, Grecians, and Romans*, the woman was placed upon an high stool; in Germany and Holland they use the chair which is described by Deventer and Heister; and for hot climates the stool is perfectly well adapted; but in northern countries, and cold weather, such a position must endanger the patient's health.

In the West Indies, and some parts of Britain, the woman is seated on a stool made in form of a femicircle; in other places she is placed on a woman's lap; and some, kneeling on a large cushion, are delivered backwards.

In France the position is chiefly that of half sitting and half lying, on the side or end of a bed; or the woman being in naked bed, is raised up with pillows or a bed-chair.

The London-method is very convenient in natural and easy labours; the patient lies in bed upon one side, the knees being contracted to the belly, and a pillow put between them to keep them asunder. But the most commodious method is to prepare a bed and a couch in the same room; a piece of oiled cloth or dressed sheep-skin is laid across the middle of each; over the under-sheet, and above this, are spread several folds of linen, pinned or tied with tape to each side of the bed and couch; these are designed to sponge up the moisture in time of labour and after delivery, while the oiled cloths or sheep skins below preserve the feather-bed from being wetted or spoiled: for this purpose, some people lay besides upon the bed several under-sheets over one another, so that by sliding out the uppermost every day, they can keep the bed dry and comfortable.

The couch must be no more than three feet wide, and provided with castors; and the woman without any other dress than that of a short or half shift, a linen skirt or petticoat open before, and a bed-gown, ought to lie down upon it, and be covered with cloaths according to the season of the year. She is commonly laid on the left side, but in that particular she is to consult her own ease; and a large sheet being doubled four times or more, one end must be slipped in below her breech, while the other hangs over the side of the couch, to be spread upon the knee of of the accoucheur or midwife, who sits behind her on a low seat. As soon as she is delivered, this sheet must be removed, a soft warm cloth applied to the os externum, and the pillow taken from between her knees: she then must be shifted with a clean, warm, half shift, linen skirt, and bed-gown, and her belly kept firm with the broad head-band of the skirt, the ends of which are to be pinned across each other. These measures being taken, the couch must be run close to the bed-side, and the patient gently moved from one to another; but, if there is no couch, the bed must be furnished with the same apparatus. Some, again, are laid across the foot of the bed, to the head of which the cloaths are previously turned up till after delivery, when the woman's posture is adapted, and then

they are rolled down again to cover and keep her warm : by this expedient, the place of a couch is supplied, and the upper part of the bed preserved soft and clean ; whereas those who are laid above the cloaths must be taken up and shifted while the bed is put to rights ; in which case, they are subject to fainting ; and to such as are very much enfeebled, this fatigue is often fatal.

Women are most easily touched, least fatigued, and kept warmest, when they lie on one side : but if the labour should prove tedious, the Parian method seems most eligible ; because when the patient half sits, half lies, the brim of the pelvis is horizontal, a perpendicular line falling from the middle space between the scrobiculus cordis and navel, would pass exactly through the middle of the basin. In this position, therefore, the weight of the waters, and, after the membranes are broke, that of the child's head, will gravitate downwards, and assist in opening the parts ; while the contracting force of the abdominal muscles and uterus, is more free, strong, and equal in this than in any other attitude. Wherefore, in all natural cases, when the labour is lingering or tedious, this or any other position, such as standing or kneeling, ought to be tried, which by an additional force, may help to push along the head, and alter its direction when it does not advance in the right way. Nevertheless, the patient must by no means be too much fatigued.

When the woman lies on the left side, the right hand must be used in touching, and *vice versa* ; unless she is laid across the bed ; in which case, either hand will equally answer the same purpose : but, if she lies athwart, with the breech towards the bed's foot, it will be most convenient to touch with the left hand when she is upon the left side, and with the right when in the opposite position. And here it will not be amiss to observe, that in the description of all the laborious and preternatural deliveries treated of in this performance, the reader must suppose the woman lying on her back, except when another posture is prescribed ; and that in natural and laborious labours, whether she be upon her side or back, the head and shoulders are a little raised into a reclining posture, so that she may breathe easily, and assist the pains.

But in preternatural labours, when there is a necessity for using great force in turning the child, the head and shoulders must lie lower than the breech, which being close to the side or foot of the bed, ought to be raised higher than either, because when the pelvis is in this situation, the hand and arm are easily pushed up in a right line, along the back part of the uterus, even to its fundus. Sometimes, however, when the feet of the child are towards the belly of the mother, they are more easily felt and managed when she lies on her side. At other times, placing the woman on her knees and elbows on a low couch, according to Daventer's method, will succeed better, by diminishing in part the strong resistance from the pressure and weight of the uterus and child, by which the feet will sometimes be easier found and delivered : but then it is safer for the child, and easier to the operator and mother, to turn her to her back before you deliver the body and head.

Of the management of women in a NATURAL LABOUR.

In a woman come to full time, labour commonly begins and proceeds in the following manner.

The os uteri is felt soft, and a little opened ; the circumference being sometimes thick, but chiefly thin : from this aperture is discharged a thick mucus, which lubricates the parts, and prepares them for stretching. This discharge usually begins some days before, and is accounted the forerunner of real labour : at the same time, the woman is seized at intervals with slight pains that gradually stretch the os uteri, fitting it for a larger dilatation ; and when labour actually begins, the pains become more frequent, strong, and lasting.

At every pain, the uterus is strongly compressed by the same effort which expels the contents of the rectum at stool, namely the inflation of the lungs, and the contraction of the abdominal muscles.

If the child be surrounded with a large quantity of waters, (see Plate CXI. fig. 4. and 6.) the uterus cannot come in contact with the body of it, but at every pain the membranes are pushed down by the fluid they contain, and the mouth of the womb being sufficiently opened by this gradual and repeated distension, they are forced into the middle of the vagina ; then the uterus contracts and comes in contact with the body of the child, and, if it be small, the head is propelled with the waters. Here the membranes usually break ; but, if that is not the case, they are pushed along towards the os externum, which they also gradually open, and appear on the outside, in the form of a large round bag. Mean while, the head advances, and the os externum being by this time fully dilated, is also protruded ; when, if the membranes, instead of bursting in the middle of the protruberance, are tore all round at the os externum, the child's head is covered with some part of them, which goes under the name of the caul, or king's hood. If the placenta is, at the same time, separated from the uterus, and the membranes remain unbroken, the secundines, waters, and child, are delivered together ; but, if the placenta adheres, they must of course give way : and should they be tore all around from the placenta, the greatest part of the body as well as the head of the child will be enveloped by them, from which it must be immediately disengaged, that the air may have a free passage into the lungs.

When the head is large, so that it does not descend immediately into the pelvis, the membranes are forced down by themselves ; and being stretched thinner and thinner, give way ; when all the waters which are farther advanced than the head, run out ; then the uterus coming in contact with the body of the child, the head is squeezed down into the mouth of the womb, which it plugs up so as to detain the rest of the waters. See Plate CXI. fig. 6.

Sometimes, when the quantity of waters is very small, and the uterus embraces the body of the child, the head, covered with the membranes, is forced downwards, and gradually opens the os internum ; but, at its arrival in the middle of the pelvis and vagina, part of the waters will be pushed down before it, sometimes in a large, and sometimes in a small proportion, towards the back part of the pelvis. At other times, when the waters are in small quantity, no part of them are to be distinguished farther than the head, which descending lower and lower, the attenuated membranes are split upon it ; while, at the same time, it fills up the mouth of the womb and up-

per part of the vagina, in such a manner as hinders the few remaining waters from being discharged at once; though in every pain, a small quantity distils on each side of the head, for lubricating the parts, so as that the child may slip along the more easily.

The uterus contracts, the pains become quicker and stronger, the crown of the head is pushed down to the lower part of the pelvis, against one of the ischia, at its lower extremity; the forehead, being at the upper part of the opposite ischium, is forced into the hollow of the under part of the sacrum, while the vertex and hindhead is pressed below the os pubis, (see Plate, CXI. fig. 7.) from whence it rises in a quarter turn, gradually opening the os externum; the frænum labiorum, or fourchette, perinæum, fundament, and the parts that intervene betwixt that and the extremity of the sacrum, are all stretched outwards in form of a large tumour. The perinæum, which is commonly but one inch from the os externum to the anus, is now stretched to three, the anus to two, and the parts between that and the coccyx are stretched from two inches to about three or more. The broad sacrospinal ligaments reaching from each side of the lower part of the sacrum, to the under part of each ischium, are also outwardly extended, and the coccyx is forced backward; while the crown of the head, where the lambdoidal crosses the end of the sagittal suture, continues to be pushed along, and dilates the os externum more and more. See

Plate CXII. fig. 1. which is intended principally to shew in what manner the perinæum and external parts are stretched by the head of the fœtus, in a first pregnancy, towards the end of labour.

- C, The clitoris and its præputium.
- D, The hairy scalp of the fœtus swelled at the vertex, in a laborious case, and protruded to the os externum.
- EF, The perinæum and anus pushed out by the head of the fœtus in form of a large tumour.
- GG, The parts that cover the tuberosities of the ossa ischia.
- H, The part that covers the os coccygis.

When the head is so far advanced, that the back part of the neck is come below the under part of the os pubis, the forehead forces the coccyx, fundament, and perinæum, backwards and downwards; then the hindhead rises about two or three inches from under the pubes, making a half round turn in its ascent, by which the forehead is equally raised from the parts upon which it pressed, and the perinæum escapes without being split or torn; at the same time, the shoulders advance into the sides of the pelvis at its brim, where it is widest, and, with the body, are forced along and delivered: mean while, by the contraction of the uterus, the placenta and chorion are loosed from the inner surface to which they adhered, and forced through the vagina, out at the os externum.

When the head rests at first above the brim of the pelvis, and is not far advanced, the fontanelle may be plainly felt with the finger, commonly towards the side of the pelvis: this is the place where the coronal crosses the sagittal suture, and the bones are a little separated

from each other, yielding a softness to the touch, by which may be distinguished four sutures, or rather one crossing another. These may be plainly perceived, even before the membranes are broke; yet the examination must not be made during a pain, when the membranes are stretched down and filled with waters; but only when the pain begins to remit, and the membranes to be relaxed; otherwise they may be broke too soon, before the os internum be sufficiently dilated, and the head properly advanced.

When the vertex is come lower down, the sagittal suture only is to be felt; because, as the hindhead descends in the pelvis, the fontanelle is turned more backwards, to the side, or towards the concavity of the sacrum: but, after it has arrived below the under part of the ossa pubis, the lambdoidal may be felt crossing the end of the sagittal suture, the occiput making a more obtuse angle than that of the parietal bones, at the place where the three are joined together. But all these circumstances are more easily distinguished after the membranes are broke, or when the head is so compressed that the bones ride over one another, provided the hairy scalp be not excessively swelled. See Plate CXI. fig. 7. — See also

Plate CXII. fig. 2. which shews in what manner the head of the fœtus is helped along with the forceps, as artificial hands, when it is necessary for the safety of either mother or child.

How and when to break the MEMBRANES.

If the child be surrounded with a large quantity of waters, the uterus cannot come in contact with the body so as to press down the head, until the membranes are pushed a considerable way before it into the vagina; nor even then, until they are broke, and the fluid diminished in such a manner as will allow the womb to contract, and, with the assistance of the pains, force along the child. When the membranes therefore are strong or unadvanced, and continue so long unbroke that the delivery is retarded, provided the os internum be sufficiently dilated, they ought to be broke without further delay; especially if the woman hath been much fatigued or exhausted with labour, or is seized with a violent flooding: in which case, the rupture of the membranes hastens delivery, and the hæmorrhage is diminished by the contraction of the uterus, which

which lessens the mouths of the vessels that are also compressed by the body of the child.

The common method of breaking the membranes is by thrusting the finger against them when they are protruded with the waters during the pain, or by pinching them with the finger and thumb; but if they are detained too high to be managed in either of these methods, the hand may be introduced into the vagina, if the os externum is so lax as to admit it easily: and if this cannot be done without giving much pain, the fore and middle fingers being pushed into the vagina with the other hand, let a probe or pair of pointed scissars be directed along and between them, and thrust through the membranes, when they are pushed with the waters below the head. This operation must be cautiously performed, lest the head should be wounded in the attempt; and as for the membranes, let the opening be never so small, the waters are discharged with force sufficient to tear them asunder.

If the vertex, instead of resting at the side of the brim of the pelvis, or at the os pubis, is forced further down to the os internum, and the waters happen to be in small quantity, the head is pushed forwards, and gradually opens the mouth of the womb without any sensible interposition of the waters: then it advances by degrees into the vagina, and the membranes being split or tore, little or nothing is discharged until the body of the child be delivered: and in this case, the hair of the head being plainly felt, will be a sufficient indication that the membranes are broke. If no hair is to be felt, but a smooth body presents itself to the touch; and the woman has undergone many strong pains, even after the mouth of the womb hath been largely dilated, and the head forced into the middle of the pelvis; you may conclude, that delivery is retarded by the rigidity of the membranes; that there is but a small quantity of waters; and that, if the containing sacs were broke, the head would come along without further hesitation.

Sometimes, no waters can be felt while the head is no farther advanced than the upper part of the pelvis, because it plugs up the passage and keeps them from descending; but, as it advances downwards, the uterus contracts, and they are forced down in a small quantity towards the back part: from thence, as the head descends, or even though it should stick in that situation, they are pushed farther down, and the membranes may be easily broke; but the task is more difficult when no waters come down, and the membranes are contiguous to the head. In this case, they must be scratched a little during every pain, with the nail of a finger, which, though short and smooth, will, by degrees, wear them thinner and thinner, until they split upon the head by the force of labour. Yet this expedient ought never to be used until you are certain that delivery is retarded by their rigidity; for, if that be not the hindrance, the difficulty must proceed from the weakness of the woman, a large head, or narrow pelvis: in which case, the delivery is a work of time, and will be obstructed by the premature discharge of the waters, which by gradually passing by the head, ought to keep the parts moist and slippery, in order to facilitate the birth: for when the membranes are not broke until the head is forced into the middle of the pelvis, the largest

part of it being then past the upper part of the sacrum, is commonly squeezed along, opens the os externum, and is delivered before all the waters are discharged from the uterus; so that what remains, by moistening and lubricating the parts, help the shoulders and body to pass with more ease. When the membranes are too soon broke, the under part of the uterus contracts sometimes so strongly before the shoulders, that it makes the resistance still greater.

In most natural labours, the space betwixt the fore and back fontanelles, viz. the vertex, presents to the os internum, and the forehead is turned to the side of the pelvis; because the basin at the brim is widest from side to side; and frequently, before the head is pushed in and fast-wedged among the bones, the child (after a pain) is felt to move and turn it to that side or situation in which it is least pressed and hurt, if it was not presenting in that position before: but this position of the head may alter, viz. in those where it is as wide, or wider, from the back part to the fore part of the brim, than from side to side, the forehead may be turned backwards or forwards. But this form of the pelvis seldom happens.

This posture is always observed in a narrow pelvis, when the upper part of the sacrum jets forward to the pubes; but, as the child is forced lower down, the forehead turns into the hollow at the inferior part of the sacrum, because the vertex and occiput find less resistance at the lower part of the ossa pubis than at the ischium, to which it was before turned; the pelvis being at the pubes, as formerly described, no more than two inches in depth, whereas at the ischium it amounts to four. If, therefore, the forehead sticks in its former situation, without turning into the hollow, it may be assisted by introducing some fingers, or the whole hand, into the vagina, during a pain, and moving it in the right position.

When the head of the fœtus presents, and is forced along in any of those positions, the labour is accounted natural; and little else is to be done, but to encourage the woman to bear down with all her strength in every pain, and to rest quietly during each interval: if the parts are rigid, dry, or inflamed, they ought to be lubricated with pomatum, hog's lard, butter, or *ung. altheæ*: the two first are most proper for the external parts; and the two last (as being harder and not so easily melted) ought to be put up into the vagina, to lubricate that and the os internum.

The mouth of the womb and os externum, for the most part, open with greater difficulty in the first than in the succeeding labours, more especially in women turned of thirty. In these cases, the os externum must be gradually dilated in every pain, by introducing the fingers in form of a cone, and turning them round, so as to stretch the parts by gentle degrees; and the whole hand being admitted into the vagina, it will be sometimes found necessary to insinuate the fingers with the flat of the hand between the head and os internum: for, when this precaution is not taken in time, the os uteri is frequently pressed before the head (especially that part of it next the pubes) even through the os externum; or if the head passes the mouth of the womb, it will protrude the parts at the os externum, and will endanger a laceration in the perineum.

periculum. This dilatation, however, ought to be cautiously performed, and never attempted except when it is absolutely necessary; even then it must be effected slowly, and in time of a pain, when the woman is least sensible of the dilating force.

When the labour happens to be lingering, though every thing be in a right posture, if the assistants are clamorous, and the woman herself too anxious and impatient to wait the requisite time without complaining, the labour will be actually retarded by her uneasiness, which we must endeavour to surmount by arguments and gentle persuasion; but if she is not to be satisfied, and strongly impressed with an opinion that certain medicines might be administered to hasten delivery, it will be convenient to prescribe some innocent medicine, that she may take between whiles, to beguile the time and please her imagination: but, if she is actually weak and exhausted, it will be necessary to order something that will quicken the circulating fluids, such as preparations of amber, castor, myrrh, volatile spirits, the *pulv. myrrh. composit.* of the *London*, or *pulv. ad partum* of the *Edinburgh Pharmacopœia*, with every thing in point of diet and drink that nourishes and strengthens the body. If the patient is of a plethoric habit, with a quick strong pulse, the contrary method is to be used, such as venesection, antiphlogistic medicines, and plentiful draughts of weak diluting fluids.

How to behave when the birth is obstructed by the navel-string or shoulders of the child, or a narrow pelvis.

Алthough the head is pushed down into the pelvis, and the vertex employed in opening the os externum, the forehead being lodged in the concavity formed by the coccyx and lower part of the sacrum; yet frequently after the labour-pain is abated, the head again is withdrawn by the navel string happening to be twisted round the neck; or when the shoulders, instead of advancing, are retarded at the brim of the pelvis, one resting over the ossa pubis, while the other is fixed at the sacrum; or when (the waters having been long evacuated) the under-part of the uterus contracts round the neck and before the shoulders, keeping up the body of the child.

When the head is therefore drawn back by any of these obstacles, and the delivery hath been retarded during several pains, one or two fingers being introduced into the rectum before the pain goes off, ought to press upon the forehead of the child at the root of the nose, great care being taken to avoid the eyes: this pressure detains the head till the return of another pain, which will squeeze it farther down, while the fingers pushing slowly and gradually, turn the forehead half round outwards and half round upwards. By this assistance, and the help of strong pains, the child will be forced along, although the neck be entangled in the navel-string; for, as the child advances, the uterus contracts, and consequently the placenta is moved lower: the funis umbilicalis will also stretch a little, without obstructing the circulation.

The head being thus kept down, the shoulders too are pressed in every succeeding pain until they are forced into the pelvis, when the whole comes along without further difficulty. And this expedient will, moreover, an-

swer the purpose, when the under-part of the uterus or os internum is contracted round the neck of the child, and before the shoulders; also, when the head is very low, pressing a finger on each side of the coccyx externally will frequently assist in the same manner; also in lingering cases, when the woman is weak, the head large, or the pelvis narrow, you may assist the delivery by gently stretching both the os externum and internum with your fingers, in time of the pains, which will increase the same, as well as dilate; but this is only to be done when absolutely necessary, and with caution, and at intervals, for fear of inflaming or lacerating the parts.

Over and above these obstacles, the head may be actually delivered and the body retained by the contraction of the os externum round the neck, even after the face appears externally. In this case it was generally allowed that the neck was close embraced by the os internum; but this seldom happens when the head is delivered, because then the os internum is kept dilated on the back-part and sides by the breast and arms of the fœtus, unless it be forced low down with or before the head.

When the head is delivered and the rest of the body retained from the largeness or wrong presenting of the shoulders, or by the navel string's being twisted round the body or neck of the child, the head must be grasped on each side, the thumbs being applied to the occiput, the fore and middle fingers extended along each side of the neck, while the third and fourth of each hand support each side of the upper jaw: thus embraced, the head must be pulled straight forwards; and if it will not move easily along, the force must be increased, and the directions varied from side to side, or rather from shoulder to shoulder, not by sudden jerks, but with a slow, firm, and equal motion. If the body cannot be moved in this manner, though you have exerted as much force as possible without running the risk of over-straining the neck, you must endeavour to slip the turns of the navel-string over the head: but should this be found impracticable, you ought not to trifle in tying the string at two places, and cutting betwixt the ligatures, as some people have advised: such an operation would engross too much time; besides, the child is in no danger of suffocating from the stricture of the funis, because it seldom or never breathes before the breast is delivered.

The better method is, immediately to slide along one or two fingers, either above or below, to one of the arm-pits; by which you try to bring along the body, while, with the other hand, you pull the neck at the same time: if it still continues unmoved, shift hands, and let the other arm-pit sustain the force; but, if this fail, cut the navel-string, and tie it afterwards. If the shoulders lie so high that the fingers cannot reach far enough to cut or take sufficient hold, let the flat of the hand be run along the back of the child: or should the os externum be strongly contracted round the neck, push up your hand along the breast, and pull as before: and should this method fail, you must have recourse to the blunt hook introduced and fixed in the arm pit; but this expedient must be used with caution, lest the child should be injured, or the parts lacerated.

The child being born, the funis umbilicalis must be divided, and the placenta delivered, according to the directions that will occur in the sequel.

How to manage the CHILD after DELIVERY.

THE child being delivered, ought to be kept warm beneath the bed-cloaths, or immediately covered with a warmed flannel or linen cloth: if it cries and breathes, the umbilical cord may be tied and cut, and the child delivered to the nurse without delay; but, if the air does not immediately rush into the lungs, and the circulation continues between it and the placenta, the operation of tying and cutting must be delayed, and every thing tried to stimulate, and sometimes to give pain. If the circulation is languid, respiration begins with difficulty, and proceeds with long intervals; and if it be entirely stopped in the funis; the child, if alive, is not easily recovered; sometimes, a great many minutes are elapsed before it begins to breathe. Whatever augments the circulating force, promotes respiration; and as this increases, the circulation grows stronger, so that they mutually assist each other. In order to promote the one and the other, the child is kept warm, moved, shaken, whipt; the head, temples, and breast rubbed with spirits, garlic, onion, or mustard applied to the mouth and nose; and the child has been sometimes recovered by blowing into the mouth with a silver casula, so as to expand the lungs.

When the placenta is itself delivered, immediately or soon after the child, by the continuance of the labour-pains, or hath been extracted by the operator, that the uterus may contract, so as to restrain too great a flooding; in this case, if the child has not yet breathed, and a pulsation is felt in the vessels, some people (with good reason) order the placenta, and as much as is possible of the navel-string, to be thrown into a basin of warm wine or water, in order to promote the circulation between them and the child; others advise us to lay the placenta on the child's belly, covered with a warm cloth; and a third set order it to be thrown upon hot ashes: but, of these, the warm water seems the most innocent and effectual expedient. Nevertheless, if the placenta is still retained in the uterus, and no dangerous flooding ensues, it cannot be in a place of more equal warmth, while the operator endeavours, by the methods above described, to bring the child to life.

In lingering labours, when the head of the child hath been long lodged in the pelvis, so that the bones ride over one another, and the shape is preternaturally lengthened, the brain is frequently so much compressed, that violent convulsions ensue before or soon after the delivery, to the danger and oft-times the destruction of the child. This disorder is frequently relieved and carried off, and the bad consequences of the long compression prevented, by cutting the navel-string before the ligature is made, or tying it so slightly as to allow two, three, or four large spoonfuls to be discharged.

If the child has been dead one or two days before delivery, the lips and genitals (especially the scrotum in boys) are of a livid hue; if it hath lain dead in the uterus two or three days longer, the skin may be easily stripped from every part of the body, and the navel-string

appears of the same colour with the lips and genitals: in ten or fourteen days, the body is much more livid and mortified, and the hairy scalp may be separated with ease; and indeed, any part of the child which hath been strongly pressed into the pelvis, and retained in that situation for any length of time, will adopt the same mortified appearance.

How to tie the FUNIS UMBILICALIS.

DIFFERENT practitioners have used different methods of performing this operation: some proposing to tie and separate the funis before the placenta is delivered; to apply one ligature close to the belly of the child, with a view to prevent a rupture of the navel; and making another two inches above the former, to divide the rope between the two tyings; by the second ligature, they mean to prevent a dangerous hæmorrhage from the woman, provided the placenta adheres to the uterus. But all these precautions are founded upon mistaken notions, and the following seems to be that which is easiest and best: If the placenta is not immediately delivered by the pains, and no flooding obliges you to hasten the extraction, the woman may be allowed to rest a little, and the child to recover; if it does not breathe, or the respiration is weak, let the methods above prescribed be put in practice, with a view to stimulate the circulation; but if the child is lively, and cries with vigour, the funis may be immediately tied in this manner: having provided a ligature or two, composed of sundry threads waxed together, so as to equal the diameter of a pack-thread, being seven inches in length, and knotted at each end, tie the navel-string about two fingers breadth from the belly of the child; by making at first one turn, if the funis be small, and securing it with two knots; but if the cord be thick, make two more turns, and another double knot; then cut the funis with a pair of sharp scissors one finger's breadth from the ligature towards the placenta; and in cutting run the scissors as near as possible to the root of the blades, else the funis will be apt to slip from the edge, and you will be obliged to make several snips before you can effect a separation: at the same time, guard the points of the scissors with your other hand. The child being washed, a linen rag is wrapped round the tied funis; which being doubled up along the belly, a square compress is laid over it, and kept firm or moderately tight with what the nurses call a belly-band, or roller round the body.

This portion of the funis soon shrinks, turns first livid, then black, and about the sixth day falls off close to the belly; and let the navel-string be tied in any part, or at any distance whatsoever from the belly, it will always drop off at the same place: so that ruptures in the navel seldom or never depend upon the tying of the funis, but may happen when the compress and belly band are not kept sufficiently firm, and continued some time after the separation of the withered portion, especially in those children that cry much: the bandage ought always to be applied so tight as not to affect respiration.

The ligature upon the funis must always be drawn so tight as to shut up the mouths of the vessels: therefore, if they continue to pour out their contents, another ligature must be applied below the former; for if this precaution

caution be neglected, the child will soon bleed to death: yet, if the navel-string is cut or tore asunder at two or three hand-breadths from the belly, and exposed to the cold without any ligature, the arteries will contract themselves, so as that little or no blood shall be lost; nay, sometimes, if the funis hath been tied and cut at the distance of three finger-breadths from the child's belly, so as that it hath been kept from bleeding for an hour or two, although the ligature be then untied, and the navel-string and belly chafed, and soaked in warm water, no more blood will be discharged.

Of delivering the PLACENTA.

THE funis being separated, and the child committed to the nurse, the next care is to deliver the placenta and membranes, if they are not already forced down by the labour-pains. We have already observed, that if there is no danger from a flooding, the woman may be allowed to rest a little, in order to recover from the fatigue she has undergone; and that the uterus may, in contracting, have time to squeeze and separate the placenta from its inner surface: during which pause also, about one, two or three tea-cups full of blood is discharged through the funis, from the vessels of the placenta, which is thus diminished in bulk, so that the womb may be the more contracted; and this is the reason for applying one ligature only upon the cord. In order to deliver the placenta, take hold of the navel-string with the left hand, turning it round the fore and middle fingers, or wrapping it in a cloth, that it may not slip from your grasp; then pull gently from side to side, and desire the woman to assist your endeavour, by straining as if she were at stool, blowing forcibly into her hand, or provoking herself to reach by thrusting her finger into her throat. If by these methods the placenta cannot be brought away, introduce your hand slowly into the vagina, and feel for the edge of the cake; which when you have found, pull it gradually along; as it comes out at the os externum, take hold of it with both hands and deliver it, bringing away, at the same time, all the membranes, which, if they adhere, must be pulled along with leisure and caution.

When the funis takes its origin towards the edge of the placenta, which is frequently the case, the cake comes easier off by pulling, than when the navel-string is inserted in the middle, unless it be uncommonly retained by its adhesion to the womb, or by the strong contraction of the os internum. If the funis is attached to the middle of the placenta, and that part presents to the os internum or externum, the whole mass will be too bulky to come along in that position: in this case you must introduce two fingers within the os externum, and bring it down with its edge foremost.

When the placenta is separated by the contraction of the uterus, in consequence of its weight and bulk, it is pushed down before the membranes, and both are brought away inverted.

When part of the placenta hath passed the os internum, and the rest of it cannot be brought along by easy pulling, because the os uteri is close contracted round the middle of it, or part of it still adheres to the womb, slide the flat

of your hand below the placenta through the os externum; and having dilated the uterus, slip down your hand to the edge of the cake, and bring it along: but, if it adheres to the uterus, push up your hand again, and having separated it cautiously, deliver it as before.

If, instead of finding the edge or middle of the placenta presenting to the os externum or internum, you feel the mouth of the womb closely contracted, you must take hold of the navel-string as above directed, and slide your other hand along the funis into the vagina; then slowly push your fingers and thumb, joined in form of a cone, through the os uteri, along the same cord, to the place of its insertion in the placenta: here let your hand rest, and feel with your fingers to what part of the uterus the cake adheres: if it be loose at the lower edge, try to bring it along; but if it adheres, begin and separate it slowly, the back of your hand being turned to the uterus, and the fore part of your fingers towards the placenta: and for this operation the nails ought to be cut short and smooth. In separating, press the ends of your fingers more against the placenta than the uterus; and if you cannot distinguish which is which, because both feel soft (though the uterus is firmer than the placenta, and this last more solid than coagulated blood;) in this case, slide down your fingers to its edge, and conduct them by the separated part, pressing it gently from the uterus, until the whole is disengaged. Sometimes, when part of it is separated, the rest will loosen and come along, if you pull gently at the detached portion; but, if this is not effected with ease, let the whole of it be separated in the most cautious manner: sometimes, also, by grasping the inside of the placenta with your hand, the whole will be loosened without further trouble. As the placenta comes along, slide down your hand and tal- hold of the lower edge, by which it must be extracted, because it is too bulky to be brought away altogether in a heap; and let it be delivered as whole as possible, keeping your thumb or fingers fixed upon the navel-string, by which means laceration is often prevented.

When the woman lies on her back, and the placenta adheres to the left side of the uterus, it will be most commodious to separate the cake with the right hand; whereas the left hand is most conveniently used when the placenta adheres to the right side of the womb; but when it is attached to the forepart, back, or fundus, either hand will answer the purpose.

That part of the uterus to which the placenta adheres, is kept still distended, while all the rest of it is contracted.

The nearer the adhesion is to the os internum, the easier is the placenta separated, and *vice versa*; because it is difficult to reach up to the fundus, on account of the contraction of the os internum, and lower part of the womb, which are not stretched again without great force after they have been contracted for any length of time.

When therefore the placenta adheres to the fundus, and all the lower part of the womb is strongly contracted, the hand must be forced up in form of a cone into the vagina, and then gradually dilate the os internum and inferior part of the uterus. If great force is required, exert it slowly, resting between whiles, that the hand may not

be cramped, nor the vagina in danger of being tore from the womb; for in this case, the vagina will lengthen considerably upwards.

While you are thus employed, let an assistant press with both hands on the woman's belly; or while you push with one hand, press with the other, in order to keep down the uterus. else it will rise high up, and roll about like a large ball, below the lax parietes of the abdomen, so as to hinder you from effecting the necessary dilatation.

When you have overcome this contraction, and introduced your hand into the fundus, separate and bring the placenta along, as above directed; and should the uterus be contracted in the middle like an hour-glass, a circumstance that sometimes, though rarely happens, the same method must be practised.

In every case, and especially when the placenta hath been delivered with difficulty, introduce your hand after its extraction, in order to examine if any part of the uterus be pulled down and inverted; and if that be the case, push it up and reduce it without loss of time, then clear it of the coagulated blood, which otherwise may occasion violent after-pains.

For the most part, in ten, fifteen, or twenty minutes, more or less, the placenta will come away of itself; and though some portion of it, or of the membranes, be left in the uterus, provided no great flooding ensues, it is commonly discharged in a day or two, without any detriment to the woman: but at any rate, if possible, all the secundines ought to be extracted at once, and before you leave your patient, in order to avoid reflections.

OF LABORIOUS LABOURS.

How LABORIOUS LABOURS are occasioned.

ALL those cases in which the head presents, and cannot be delivered in the natural way, are accounted more or less laborious, according to the different circumstances from which the difficulty arises: and these commonly are, first, Great weakness, proceeding from loss of appetite and bad digestion; frequent vomitings, diarrhoeas, or dysenteries, floodings, or any other disease that may exhaust the patient; as also the fatigue she may have undergone by unskilful treatment in the beginning of labour.

Secondly, From excessive grief and anxiety of mind, occasioned by the unseasonable news of sudden misfortune in time of labour; which often affect her so, as to carry off the pains, and endanger her sinking under the shock.

Thirdly, From the rigidity of the os uteri, vagina, and external parts, which commonly happens to women in the first birth, especially to those who are about the age of forty: though it may be also owing to large callosities, produced from laceration or ulceration of the parts; or to glands and scirrhus tumours that block up the vagina.

Fourthly, When the under-part of the uterus is contracted before the shoulders, or the body entangled in the navel-string.

Fifthly, From the wrong presentation of the child's head; that is, when the forehead is towards the groin or middle of the os pubis; when the face presents with the

chin to the os pubis, ischiûm, or sacrum; when the crown of the head rests above the os pubis, and the forehead or face is pressed into the hollow of the sacrum; and lastly, when one of the ears presents.

Sixthly, From the extraordinary ossification of the child's head, by which the bones of the skull are hindered from yielding, as they are forced into the pelvis; and form a hydrocephalus or dropsy, distending the head to such a degree, that it cannot pass along until the water is discharged.

Seventhly, From a too small or distorted pelvis, which often occurs in very little women, or such as have been rickety in their childhood. See Plate CXII. fig. 6. 7.

In all these cases, except when the pelvis is too narrow and the head too large, provided the head lies at the upper-part of the brim, or (though pressed into the pelvis) can be easily pushed back into the uterus, the best method is, to turn the child and deliver by the feet; but, if the head is pressed into the middle or lower part of the pelvis, and the uterus strongly contracted round the child, delivery ought to be performed with the forceps; and in all the seven cases, if the woman is in danger, and if you can neither turn, nor deliver with the forceps, the head must be opened and delivered with crochets. Laborious cases, from some of the above-recited causes, happen much oftener than those we call preternatural; but, those which proceed from a narrow pelvis, or a large head, are of the worst consequence. These cases demand greater judgment in the operator than those in which the child's head does not present; because in these last we know, that the best and safest method is to deliver by the feet; whereas in laborious births, we must maturely consider the cause that retards the head from coming along, together with the necessary assistance required; we must determine when we ought to wait patiently for the efforts of nature, and when it is absolutely necessary to come to her aid. If we attempt to succour her too soon, and use much force in the operation, so that the child and mother, or one of the two, are lost, we will be apt to reproach ourselves for having acted prematurely; upon the supposition, that if we had waited a little longer, the pains might have, by degrees, delivered the child; or at least, forced the head so low, as that we might have extracted it with more safety, by the assistance of the forceps. On the other hand, when we leave it to nature, perhaps by the strong pressure upon the head and brain, the child is dead when delivered, and the woman so exhausted with tedious labour, that her life is in imminent danger: in this case, we blame ourselves for delaying our help so long, reflecting that had we delivered the patient sooner, without paying such scrupulous regard to the life of the child, the woman might have recovered without having run such a dangerous risk. Doubtless it is our duty to save both mother and child, if possible; but, if that is impracticable, to pay our chief regard to the parent; and in all dubious cases, to act cautiously and circumspectly, to the best of our judgment and skill.

If the head is advanced into the pelvis, and the uterus strongly contracted round the child, great force is required to push it back into the womb, because the effort must be sufficient

Fig. 5.

Fig. 8.

sufficient to stretch the uterus, so as to re-admit the head, together with your hand and arm; and even then the child will be turned with great difficulty.

Should you turn when the head is too large, you may bring down the body of the child, but the head will stick fast above, and cannot be extracted without the help of forceps or crotchets; (see explanation of Plate CXIII. fig. 5. below) yet the case is still worse in a narrow pelvis, even though the head be of an ordinary size. When things are so situated, you should not attempt to turn, because in so doing you may give the woman a great deal of pain, and yourself much unnecessary fatigue: you ought therefore to try the forceps, and if they do not succeed, diminish the size of the head, and extract it, as shall be afterwards shewn.

Plate CXIII. fig. 5. represents, in a lateral view of the pelvis, the method of extracting, with the assistance of a curved crotchet, the head of the fœtus, when left in the uterus, after the body is delivered and separated from it; either by its being too large, or the pelvis too narrow.

ABC. The os sacrum and coccyx.

D. The os pelvis of the left side.

EE. The uterus.

F. The locking part of the crotchet.

g,h,i. The point of the crotchet on the inside of the cranium.

Of the FILLETS and FORCEPS.

WE have already observed, that the greatest number of difficult and lingering labours proceed from the head's sticking fast in the pelvis, which situation is occasioned by one of the seven causes recited above: when formerly this was the case, the child was generally lost, unless it could be turned and delivered by the feet; or if it could be extracted alive, either died soon after delivery, or recovered with great difficulty from the long and severe compression of the head, while the life of the mother was endangered from the same cause as above described: for, the pressure being reciprocal, the fibres and vessels of the soft parts contained in the pelvis are bruised by the child's head, and the circulation of the fluids obstructed; so that a violent inflammation, and sometimes a sudden mortification, ensues. If the child could not be turned, the method practised in these cases, was to open the head and extract with the crotchet; and this expedient produced a general clamour among the women, who observed, that when recourse was had to the assistance of a man-midwife, either the mother or child, or both, were lost. This censure, which could not fail of being a great discouragement to male practitioners, stimulated the ingenuity of several gentlemen of the profession, in order to contrive some gentler method of bringing along the head, so as to save the child, without any prejudice to the mother.

Their endeavours have not been without success: a more safe and certain expedient for this purpose hath been invented, and of late brought to greater perfection in this than in any other kingdom; so that if we are called in before the child is dead, or the parts of the woman in danger of a mortification, both the fœtus and mother may frequently be happily saved. This fortunate contrivance

is no other than the forceps, which was, as is alledged, first used here by the *Chamberlains*, by whom it was kept as a nostrum, and after their decease so imperfectly known, as to be seldom applied with success: so that different practitioners had recourse to different kinds of fillets or lacks. Blunt hooks also of various make were invented in *England, France*, and other parts. The forceps, since the time of *Dr Chamberlain*, have undergone several alterations, particularly in the joining, handles, form, and composition.

The common way of using them formerly, was by introducing each blade at random, taking hold of the head any how, pulling it straight along, and delivering with downright force and violence; by which means, both os internum and externum were often tore, and the child's head much bruised. On account of these bad consequences, they had been altogether disused by many practitioners; some of whom endeavoured, in lieu of them, to introduce divers kinds of fillets over the child's head; but none of them can be so easily used, or have near so many advantages, as the forceps, when rightly applied and conducted.

For my own part, says *Dr Smellie*, finding in practice that, by the directions of *Chapman, Giffard*, and *Gregoire* at *Paris*, I frequently could not move the head along without contusing it, and tearing the parts of the woman; for they direct us to introduce the blades of the forceps where they will easiest pass, and taking hold of the head in any part of it, to extract with more or less force, according to the resistance; I began to consider the whole in a mechanical view, and reduce the extraction of the child to the rules of moving bodies in different directions: in consequence of this plan, I more accurately surveyed the dimensions and form of the pelvis, together with the figure of the child's head, and the manner in which it passed along in natural labours: and from the knowledge of these things, I not only delivered with greater ease and safety than before, but also had the satisfaction to find in teaching, that I could convey a more distinct idea of the art in this mechanical light than in any other; and particularly, give more sure and solid directions for applying the forceps, even to the conviction of many old practitioners, when they reflected on the uncertainty attending the old method of application. From this knowledge, too, joined with experience, and hints which have occurred and been communicated to me, I have been led to alter the form and dimensions of the forceps, so as to avoid the inconveniencies that attended the use of the former kinds. See Plate CXIII. fig. 6.

A, The straight forceps, in the exact proportion as to the width between the blades, and length from the points to the locking part; the first being two and the second six inches, which, with three inches and a half, (the length of the handles), make in all eleven inches and a half.

B represents the posterior part of a single blade, in order to shew the width and length of the open part of the same, and the form and dimensions of the whole.

C, The blunt hook, which is used for three purposes: 1. To assist the extraction of the head, after the cranium is opened with the scissors, by introducing the

the small end along the ear on the outside of the head to above the under-jaw, where the point is to be fixed; the other extremity of the hook being held with one hand, whilst two fingers of the other are to be introduced into the foresaid opening, by which holds the head is to be gradually extracted.

2. The small end is useful in abortions, in any of the first four or five months, to hook down the secundines, when lying loose in the uterus, when they cannot be extracted by the fingers, or labour-pains, and when the patient is much weakened by floodings.

3. The large hook at the other end is useful to assist the extraction of the body, when the breech presents; but should be used with great caution, to avoid the dislocation or fracture of the thigh.

The lacks or fillets are of different kinds, of which the most simple is a noose made on the end of a fillet or limber garter: but this can only be applied, before the head is fast jammed in the pelvis, or when it can be pushed up and raised above the brim. The os externum and internum having been gradually dilated, this noose must be conveyed on the ends of the fingers, and slipped over the fore and hind head. There are also other kinds differently introduced upon various blunt instruments, too tedious either to describe or use: but the most useful of all these contrivances, is a fillet made in form of a sheath, mounted upon a piece of slender whale-bone, about two feet in length, which is easier applied than any other expedient of the same kind. See Plate CXIII. fig. 7.

A represents the whale-bone fillet, which may be sometimes useful in labour cases, when the operator is not provided with the forceps, in sudden and unexpected exigencies.

BB, Two views of a pessary for the prolapsus uteri. After the uterus is reduced, the large end of the pessary is to be introduced into the vagina, and the os uteri retained in the concave part, where there are three holes to prevent the stagnation of any moisture. The small end without the os externum has two tapes drawn through the two holes, which are tied to four other tapes, that hang down from a belt that surrounds the woman's body, and by this means keep up the pessary. This pessary may be taken out by the patient when she goes to bed, and introduced again in the morning; but as this sometimes rubs the os externum, so as to make its use uneasy, the round kind, marked C, are of more general use. They are made of wood, ivory, or cork, (the last covered with cloth and dipt in wax:) The pessary is to be lubricated with pomatum, the edge forced through the passage into the vagina, and a finger introduced in the hole in the middle lays it across within the os externum. They ought to be larger or smaller, according to the wideness or narrowness of the passage, to prevent their being forced out by any extraordinary straining.

DD gives two views of a female catheter, to shew its degree of curvature and different parts.

When the head is high up in the pelvis, if the woman has been long in labour, and the waters discharged for a considerable time, the uterus being strongly contracted,

so as that the head and shoulders cannot be raised, or the child turned to be delivered by the feet, while the mother is enfeebled, and the pains so weak, that, unless assisted, she is in danger of her life; also, when the os internum, vagina, and labia pudendi, are inflamed, and tumefied; or when there is a violent discharge of blood from the uterus, provided the pelvis is not too narrow, nor the head too large, this fillet may be successfully used; in which case, if the os externum and internum are not already sufficiently open, they must be gradually dilated as much as possible, by the hand, which at the same time must be introduced and passed along the side of the head, in order to ascertain the position thereof. This being known, let the other hand introduce the double of the whale-bone and fillet over the face and chin, where you can have the best purchase, and where it will be least apt to slip and lose its hold. This application being effected, let the hand be brought down, and the whale-bone drawn from the sheath of the fillet, which (after the ends of it are tied together) must be pulled during every pain, pressing at the same time with the other hand, upon the opposite part of the head, and using more or less force according to the resistance.

The disadvantage attending all fillets, is the difficulty in introducing and fixing them: and though this last is easier applied than the others; yet when the vertex presents, the child's chin is so pressed to the breast, that it is often impracticable to insinuate the fillet between them; and if it is fixed upon the face or hind head, it frequently slips off, in pulling: but, granting it commodiously fixed, when the head is large, or the pelvis narrow; so that we are obliged to pull with great force, the fillet will gall, and even cut the soft parts to the very bone; and if the child comes out of a sudden, in consequence of violent pulling, the external parts of the woman are in great danger of sudden laceration: but, if the head is small, and comes along with a moderate force, the child may be delivered by this contrivance, without any bad consequence: though in this case, we find by experience, that unless the woman has some very dangerous symptom, the head will in time slide gradually down into the pelvis, even when it is too large to be extracted with the fillet or forceps, and the child be safely delivered by the labour-pains, although slow and lingering, and the mother seems weak and exhausted, provided she be supported with nourishing and strengthening cordials.

As the head in the 6th and 7th cases is forced along the pelvis, commonly in these laborious cases, the bones of the cranium are so compressed, that they ride over one another, so that the bulk of the whole is diminished, and the head, as it is pushed forward, is, from a round, altered into an oblong figure: when therefore it is advanced into the pelvis, where it sticks fast for a considerable time, and cannot be delivered by the labour pains, the forceps may be introduced with great ease and safety, like a pair of artificial hands, by which the head is very little (if at all) marked, and the woman very seldom tore. But if the head is detained above the brim of the pelvis, or a small portion of it only farther advanced, and it appears, that the one being too narrow, or the other too large, the woman cannot be delivered by the strongest labour pains;

in that case, the child cannot be saved either by turning and bringing it by the feet, or delivered by the application of fillet or forceps; but the operator must unavoidably use the dilagreeable method of extracting with the crochets. Nevertheless, in all these cases, the forceps ought first to be tried; and sometimes they will succeed beyond expectation, provided the birth is retarded by the weakness of the woman, and the second, third, fourth, or fifth obstructions: but they cannot be depended upon even when the vertex presents, with the forehead to the side or back part of the pelvis, and (though the woman has had strong pains for many hours after the membranes are broke) the head is not forced down into the pelvis, or at least, but an inconsiderable part of it, resembling the small end of a sugar-loaf. For, from these circumstances, you may conclude, that the largest part of it is still above the brim, and that either the head is too large, or the pelvis too narrow. Even in these cases, indeed, the last fillet or a long pair of forceps may take such firm hold, that, with great force and the strong purchase, the head will be delivered; but such violence is commonly fatal to the woman, by causing such an inflammation, and perhaps laceration of the parts, as is attended with mortification.

When the head is high, the forceps may be locked in the middle of the pelvis; but in that case, great care must be taken in feeling with the fingers all round, that no part of the vagina be included in the locking. Sometimes, when the head rests, or is pressed too much on the fore-part or side of the pelvis, either at the brim or lower down, by introducing one blade, it may be moved farther down, provided the labour-pains are strong, and the operation assisted by the fingers of the other hand applied to the opposite side of the head; but if the fingers cannot reach high enough, the best method is to turn or move the blade towards the ear of the child, and introduce the other along the opposite side.

General rules for using the FORCEPS.

THE farther the head is advanced in the pelvis, the easier it is delivered with the forceps; because then, if in the 6th or 7th case, it is changed from a round to an oblong figure, by being forced along by the labour-pains: on the contrary, when the head remains high up, resting upon the brim of the pelvis, the forceps are used with greater difficulty and uncertainty.

The os externum must be gradually opened by introducing the fingers one after another, in form of a cone, after they have been lubricated with pomatum, moving and turning them in a semicircular motion, as they are pushed up. If the head is so low down that the hand cannot be introduced high up in this form, let the parts be dilated by the fingers turned in the direction of the coccyx, the back of the hand being upwards, next to the child's head: the external parts being sufficiently opened to admit all the fingers, let the back of the hand be turned to the perineum, while the fingers and thumb being flattened, will slide along betwixt the head and the os sacrum. If the right hand be used, let it be turned a little to the left side of the pelvis, because the broad ligament and membrane that fill up the space between the

sacrum and ischia, will yield and allow more room for the fingers to advance; for the same reason, when the left hand is introduced, it must be turned a little to the right side. Having gained your point so far, continue to push up, until your fingers pass the os internum; at the same time, with the palm of your hand, raise or scoop up the head; by which means, you will be more at liberty to reach higher, dilate the internal parts, and distinguish the situation and size of the head, together with the dimensions of the pelvis: from which investigation, you will be able to judge, whether the child ought to be turned and brought by the feet, or delivered with the forceps; or, if the labour-pains are strong, and the head presents tolerably fair, without being jammed in the pelvis, you will resolve to wait some time, in hope of seeing the child delivered by the labour-pains, especially when the woman is in no immediate danger, and the chief obstacle is the rigidity of the parts.

The position of the head is distinguished by feeling for one of the ears, the fore or smooth part of which is towards the face of the child; if it cannot be ascertained by this mark, the hand and fingers must be pushed farther up, to feel for the face or back part of the neck; but, if the head cannot be traced, the observation must be taken from the fontanelle, or that part of the cranium where the lambdoidal crosses the end of the sagittal suture. When the ears of the child are towards the sides of the pelvis, or diagonal, the forehead being either to the sacrum or pubes, the patient must lie on her back, with her breech a little over the bed. If one ear is to the sacrum, and the other to the pubes, she must be laid on one side, with her breech over the bed, as before, her knees being pulled up to her belly, and a pillow placed between them; except when the upper part of the sacrum jets too much forward; in which case, she must lie upon her back, as above described.

The blades of the forceps ought always, if possible, to be introduced along the ears; by which means, they approach nearer to each other, gain a firmer hold, and hurt the head less than in any other direction: frequently, indeed, not the least mark of their application is to be perceived; whereas, if the blades are applied along the forehead and occiput, they are at a greater distance from each other, require more room, frequently at their points press in the bones of the skull, and endanger a laceration in the os externum of the woman. See Plate CXII. fig. 2.

The woman being laid in a right position for the application of the forceps, the blades ought to be privately conveyed between the feather-bed and the cloaths, at a small distance from one another, or on each side of the patient: that this conveyance may be the more easily effected, the legs of the instrument ought to be kept in the operator's side-pockets. Thus provided, when he sits down to deliver, let him spread the sheet that hangs over the bed, upon his lap, and under that cover, take out and dispose the blades on each side of the patient; by which means, he will often be able to deliver with the forceps, without their being perceived by the woman herself, or any other of the assistants. Some people pin a sheet to each shoulder, and throw the other end over the bed,

bed, that they may be the more effectually concealed from the view of those who are present: but this method is apt to confine and embarrass the operator. At any rate, as women are commonly frightened at the very name of an instrument, it is advisable to conceal them as much as possible, until the character of the operator is fully established.

The different ways of using the FORCEPS.

When the Head is down to the Os Externum.

WHEN the head presents fair, with the forehead to the sacrum, the occiput to the pubes, and the ears to the sides of the pelvis, or a little diagonal; in this case, the head is commonly pretty well advanced in the basin, and the operator seldom miscarries in the use of the forceps. Things being thus situated, let the patient be laid on her back, her head and shoulders being somewhat raised, and the breech advanced a little over the side or foot of the bed; while the assistants sitting on each side support her legs, at the same time keeping her knees duly separated and raised up to the belly, and her lower parts always covered with the bed cloaths, that she may not be apt to catch cold. In order to avoid this inconvenience, if the bed is at a great distance from the fire, the weather cold, and the woman of a delicate constitution, a chafing-dish with charcoal, or a vessel with warm water, should be placed near, or under the bed. These precautions being taken, let the operator place himself upon a low chair, and having lubricated with pomatum the blades of the forceps, and also his right hand and fingers, slide first the hand gently into the vagina, pushing it along in a flattened form, between that and the child's head, until the fingers have passed the os internum; then, with his other hand, let him take one of the blades of the forceps from the place where it was deposited, and introduce it betwixt his right hand and the head; if the point or extremity of it should stick at the ear, let it be slipped backward a little, and then guided forwards with a slow and delicate motion; when it shall have passed the os uteri, let it be advanced still farther up, until the rest at which the blades lock into each other be close to the lower part of the head, or at least within an inch thereof.

Having in this manner introduced one blade, let him withdraw his right hand, and infinate his left in the same direction, along the other side of the head, until his fingers shall have passed the os internum; then taking out the other blade from the place of concealment, with the hand that is disengaged, let it be applied to the other side of the child's head, by the same means employed in introducing the first; then the left hand must be withdrawn, and the head being embraced between the blades, let them be locked in each other. Having thus secured them, he must take a firm hold with both hands, and, when the pain comes on, begin to pull the head along from side to side, continuing this operation during every pain until the vertex appears through the os externum, and the neck of the child can be felt with the finger below the os pubis; at which time, the forehead pushes out the perineum like a large tumour: then let him stand up, and raising the handles of the forceps, pull the head upwards

also, that the forehead being turned half round upwards, the perineum and lower parts of the os externum may not be tore.

In stretching the os externum or internum, we ought to imitate nature: for in practice we find, that when they are opened slowly, and at intervals, by the membranes with the waters, or the child's head, the parts are seldom inflamed or lacerated: but in all natural labours, when these parts are suddenly opened, and the child delivered by strong and violent pains, without much intermission, this misfortune sometimes happens, and the woman is afterwards in great pain and danger.

We ought therefore, when obliged to dilate those parts, to proceed in that slow, deliberate manner; and though upon the first trial, they feel so rigid, that one would imagine they could never yield or extend; yet, by stretching with the hand, and resting by intervals, we can frequently overcome the greatest resistance. We must also, in such cases, be very cautious, pulling slowly, with intermissions, in order to prevent the same lacerations: for which purpose too, we ought to lubricate the perineum with pomatum, during those short intervals, and keep the palm of one hand close pressed to it and the neighbouring parts, while with the other we pull at the extremity of the handles of the forceps; by which means, we preserve the parts, and know how much we may venture to pull at a time. When the head is almost delivered, the parts, thus stretched, must be slipped over the forehead and face of the child, while the operator pulls upwards with the other hand, turning the handles of the forceps to the abdomen of the woman.

This method of pulling upwards, raises the child's head from the perineum, and the half-round turn to the abdomen of the mother brings out the forehead and face from below; for, when that part of the hind-head which is joined to the neck, rests at the under-part of the os pubis, the head turns upon it, as upon an axis. In preternatural cases also, the body being delivered, must in the same manner be raised up over the belly of the mother, and at the same time the perineum slipped over the face and forehead of the child.

In the introduction of the forceps, let each blade be pushed up in an imaginary line from the os externum, to the middle space betwixt the navel and *scrobiculus cordis* of the woman; or, in other words, the handles of the forceps are to be held as far back as the perineum will allow. The introduction of the other hand to the opposite side, will, by pressing the child's head against the first blade, detain it in its proper place till the other can be applied; or, if this pressure should not seem sufficient, it may be supported by the operator's knee.

When the head is come low down, and cannot be brought farther, because one of the shoulders rests above the os pubis, and the other upon the upper-part of the sacrum, let the head be strongly grasped with the forceps, and pushed up as far as possible, moving from blade to blade as you push up, that the shoulders may be the more easily moved to the sides of the pelvis, by turning the face or forehead a little towards one of them; then, the forehead must be brought back again into the hollow of the sacrum, and another effort made to deliver: but,

should

should the difficulty remain, let the head be pushed up again, and turned to the other side; because it is uncertain which of the shoulders rests on the os pubis, or sacrum. Suppose, for example, the right shoulder of the child sticks above the os pubis, the forehead being in the hollow of the sacrum; in this case, if the forehead be turned to the right-hand side of the woman, the shoulder will not move; whereas, if it be turned to the left, and the head at the same time pushed a little upwards, so as to raise and disengage the parts that were fixed, the right shoulder being towards the right hand side, and the other to the left side of the brim of the pelvis, when the forehead is turned back again into the hollow of the sacrum, the obstacle will be removed, and the head be more easily delivered. This being performed, let the forceps be unlocked, and the blades disposed cautiously under the cloaths so as not to be discovered; then proceed to the delivery of the child, which, when the navel-string is cut and tied, may be committed to the nurse. The next care is to wipe the blades of the forceps, singly, under the cloaths, slide them warily into your pockets, and deliver the placenta.

When the forehead is to the Os Pubis.

WHEN the forehead, instead of being towards the sacrum, is turned forwards to the os pubis, the woman must be laid in the same position as in the former case; because here also, the ears of the child are towards the sides of the pelvis, or a little diagonally situated, provided the forehead is towards one of the groins. The blades of the forceps being introduced along the ears, or as near them as possible, according to the foregoing directions, the head must be pushed up a little, and the forehead turned to one side of the pelvis; thus let it be brought along, until the hindhead arrives at the lower part of the ischium: then the forehead must be turned backward, into the hollow of the sacrum, and even a quarter or more to the contrary side, in order to prevent the shoulders from hitching on the upper part of the os pubis, or sacrum, so that they may be still towards the sides of the pelvis; then let the quarter turn be reversed, the forehead being replaced in the hollow of the sacrum, the head may be extracted as above. In performing these different turns, let the head be pushed up or pulled down occasionally, as it meets with least resistance. In this case, when the head is small, it will come along as it presents; but if large, the chin will be so much pressed against the breast, that it cannot be brought up with the half round turn, and the woman will be sore if it comes along. See Plate CXII. where

FIG. 3. shews the head of the fœtus, by strong labour-pains, squeezed into a longish form, with a tumour on the vertex, from a long compression of the head in the pelvis.

K, The tumour on the vertex.

L, The forceps.

M, The vesica urinaria much distended with a large quantity of urine from the long pressure of the head against the urethra.

N, The under part of the uterus.

OO, The os uteri.

When it presents fair at the brim of the Pelvis.

WHEN the forehead and face of the child are turned to the side of the pelvis, (in which case it is higher than in the first situation), it will be difficult, if the woman lies on her back, to introduce the forceps so as to grasp the head with a blade over each ear; because the head is often pressed so hard against the bones, in this position, that there is no room to insinuate the fingers between the ear and the os pubis. so as to introduce the blades safely, on the inside of the os internum, or push one of them up between the fingers and the child's head. When things are so situated, the best posture for the woman is that of lying on one side, as formerly directed, because the bones will yield a little, and the forceps (of consequence) may be the more easily introduced.

Suppose her lying on her left side, and the forehead of the child turned to the same side of the pelvis; let the fingers of the operator's right hand be introduced along the ear, between the head and the os pubis, until they pass the os internum: if the head is so immovably fixed in the pelvis, that there is no passage between them, let his left hand be pushed up between the sacrum and the child's head, which being raised as high as possible, above the brim of the pelvis, he will have room sufficient for his fingers and forceps; then let him slide up one of the blades, with the right hand, remembering to press the handle backwards to the perinæum, that the point may humour the turn of the sacrum and child's head: this being effected, let him withdraw his left hand, with which he may hold the handle of the blade, already introduced, while he insinuates the fingers of his right hand at the os pubis, as before directed, and pushes up the other blade, slowly and gently, that he may run no risk of hurting the os internum or bladder; and here also keep the handle of it as far backwards as the perinæum will allow: when the point has passed the os internum, let him slide it up farther, and join the legs by locking them together, keeping them still in a line with the middle space betwixt the navel and scrobiculus cordis. Then let him pull along the head, moving it from side to side, or from one ear of the child to the other; when it is sufficiently advanced, let him move the forehead into the hollow of the sacrum, and a quarter-turn farther, then bring it back into the same cavity; but, if the head will not easily come along, let the woman be turned on her back after the forceps have been fixed, and the handles firmly tied with a garter or fillet; let the hindhead be pulled half round outwards, from below the os pubis, and the instrument and child managed as before.

In all those cases that require the forceps, if the head cannot be raised above the brim of the pelvis, or the fingers introduced within the os internum, to guide the points of the forceps along the ears, especially at the ossa pubis, ischia, or sacrum; let the fingers and hand be pushed up as far as they will go, along the open space betwixt the sacrum and ischium; then one of the blades may be introduced, moved to, and fixed over the ear, the situation of which is already known: the other hand may be introduced, and the other blade conducted in the same manner, on the opposite side of the pelvis; but, before they

they are locked together, care must be taken that they are exactly opposite to each other, and both sufficiently introduced. In this case, if the operator finds the upper part of the sacrum jetting, in so much that the point of the forceps cannot pass it, let him try with his hand to turn the forehead a little backwards, so that one ear will be towards the groin, and the other towards the side of that prominence; consequently, there will be more room from the blades to pass along the ears: but if the forehead should remain immovable, or though moved return to its former place, let one blade be introduced behind one ear, and its fellow before the other, in which case the introduction is sometimes more easily performed when the woman lies on her back, than when she is laid on one side. See Plate CXII. fig. 2.

When the FACE presents.

When the face presents, resting on the upper part of the pelvis, the head ought to be pushed up to the fundus uteri, the child turned and brought by the feet, because the hind head is turned back on the shoulders, and, unless very small, cannot be pulled along with the forceps; but should it advance pretty fast in the pelvis, it will be sometimes delivered alive, without any resistance. But, if it descends slowly, or, after it is low down, sticks for a considerable time, the long pressure on the brain frequently destroys the child, if not relieved in time, by turning or extracting with the forceps.

When the head is detained very high up, and no signs of its descending appear, and the operator having stretched the parts with a view to turn, discovers that the pelvis is narrow, and the head large, he must not proceed with turning, because after this hath been performed, perhaps with great difficulty, the head cannot be delivered without the assistance of the crotchet. No doubt it would be a great advantage in all cases where the face or forehead presents, if we could raise the head so as to alter the bad position, and move it so, with our hand, as to bring the crown of the head to present: and indeed this should always be tried, and more especially, when the pelvis is too narrow, or the head too large; and when we are dubious of saving the child by turning: but frequently this is impossible to be done, when the waters are evacuated, the uterus strongly contracted on the child, and the upper part of the head so slippery as to elude our hold; inasmuch that, even when the pressure is not great, we seldom succeed, unless the head is small, and then we can save the child by turning. If you succeed, and the woman is strong, go on as in natural labour; but, if this fails, then it will be more advisable to wait with patience for the descent of the head, so as that it may be delivered with the forceps; and consequently the child may be saved; but, if it still remains in its high situation, and the woman is weak and exhausted, the forceps may be tried; and, should they fail, recourse must be had to the crotchet; because the mother's life is always to be more regarded than the safety of the child.

When the face of the child is come down, and sticks at the os externum, the greatest part of the head is then squeezed down into the pelvis, and if not speedily delivered, the child is frequently lost by the violent com-

pression of the brain: besides, when it is so low down, it seldom can be returned, on account of the great contraction of the uterus. In this case, when the chin is turned towards the os pubis, at the lower part of that bone, the woman must be laid on her back, the forceps introduced, as formerly directed in the first case, and when the chin is brought out from under the os pubis, the head must be pulled half round upwards; by which means the fore and hind head will be raised from the perineum, and the under part of the os externum prevented from being tore.

If the chin points to either side of the pelvis, the woman must be laid on her side, the blades of the forceps introduced along the ears, one at the os pubis, and the other at the sacrum; and the chin, when brought lower down, turned to the pubis, and delivered: for the pelvis being only two inches in depth at this place, the chin is easily brought from under it, and then the head is at liberty to be turned half round upwards; because the chin being disengaged from this bone, can be pulled up over it externally; by which means, two inches of room, at least, will be gained, for the more easy delivery of the fore and hind head, which are now pressed against the perineum. When the chin is towards the sacrum, the hind head pressed back betwixt the shoulders, so that the face is kept from rising up below the os pubis, the head must be pushed up with the hand, to the upper part of the pelvis, and the forceps introduced and fixed on the ears; the hindhead must be turned to one side of the pelvis, while the chin is moved to the other side, and, if possible, to the lower part of the ischium; then the hind head must be brought into the hollow of the sacrum, with the chin below the os pubis, and delivered as above directed. If this cannot be done, let the operator try, with the forceps, to pull down the hind-head below the os pubis, and at the same time, with the fingers of the other hand, push the face and forehead backwards and upwards into the hollow of the sacrum.

For when the chin points to the back part of the pelvis, the forehead is squeezed against the os pubis, while the hind-head is pressed upon the back, betwixt the shoulders; so that the head cannot be delivered unless, the occiput can be brought out from below the os pubis, as formerly described. See Plate CXII. fig. 4, and 5.

FIG. 4. shews, in the lateral view the face of the child presenting and forced down into the lower part of the pelvis, the chin being below the pubes, and the vertex in the concavity of the os sacrum: The water being likewise all discharged, the uterus appears closely joined to the body of the child.

FIG. 5. shews, in a lateral view, the head of the child in the same position as in the former figure.

AB, The vertebrae of the loins, os sacrum, and coccyx.

C, The os pubis of the left side.

D, The inferior part of the rectum.

E, The perineum.

F, The left labium pudendi.

GGG, The uterus.

The sum of all that has been said on this head, may be comprehended in the following general maxims.

Young practitioners are often at a loss to know and judge

judge by the touch in the vagina, when the head is far enough down in the basin for using the forceps. If we were to take our observations from what we feel of the head at the os pubis, we should be frequently deceived; because in that place the pelvis is only two inches in depth, and the head will seem lower down than it really is: but if, in examining backwards, we find little or no part of it towards the sacrum, we may be certain that all the head is above the brim: if we find it down as far as the middle of the sacrum, one third of it is advanced; if as far down as the lower part, one half; and in this case, the largest part is equal with the brim. When it is in this situation, we may be almost certain of succeeding with the forceps; and when the head is so low as to protrude the external parts, they never fail. But these things will differ according to different circumstances, that may occasion a tedious delivery.

Let the operator acquire an accurate knowledge of the figure, shape, and dimensions of the pelvis, together with the shape, size, and position of the child's head.

Let the breech of the woman be always brought forwards, a little over the bed, and her thighs pulled up to her belly, whether she lies on her side or back, to give room to apply, and to move the forceps up or down, or from side to side.

Let the parts be opened and the fingers pass the os internum: in order to which, if it cannot be otherwise accomplished, let the head be raised two or three inches, that the fingers may have more room; if the head can be raised above the brim your hand is not confined by the bores; for, as we have already observed, the pelvis is wider from side to side, at the brim, than at the lower part; if the fingers are not past the os uteri, it is in danger of being included betwixt the forceps and the child's head.

The forceps, if possible, should pass along the ears, because, in that case, they seldom or never hurt or mark the head.

They ought to be pushed up in an imaginary line, towards the middle space between the navel and scrobiculus cordis, otherwise the ends will run against the sacrum.

The forehead ought always to be turned into the hollow of the sacrum, when it is not already in that situation. When the face presents, the chin must be turned to below the os pubis, and the hind-head into the hollow of the sacrum.

When the shoulders rest at the pubes, where they are detained, the head must be turned a large quarter to the opposite side, so as that they may lie towards the sides of the pelvis.

The head must always be brought out with an half round turn, over the outside of the os pubis, for the preservation of the perineum, which must at the same time be supported with the flat of the other hand, and slide gently backwards over the head.

When the head is so low as to protrude the parts, in form of a large tumour, and the vertex hath begun to dilate the os externum, but, instead of advancing, is long detained in that situation, from any of the forementioned causes of laborious cases, and the operator cannot exactly distinguish the position of the head, let him introduce a finger between the os pubis and the head, and he will

frequently find the back part of the neck, or one ear, at the forepart, or towards the side of the pelvis: when the situation is known, he needs not stretch the os externum, and raise the head, as formerly directed; but he may introduce the forceps, and they being properly joined, and their handles tied, pull gently during every pain; or if the pains are gone, at the interval of four or five minutes, that the parts may be slowly dilated, as they are in the natural labour: but, when the situation cannot be known, the head ought to be raised. The same method may also be taken when the face presents, and is low in the pelvis, except when the chin is toward the back part: and in this case, the head ought to be raised likewise.

Almost all these directions are to be followed, except when the head is small, in which case it may be brought along by the force of pulling: but this only happens when the woman is reduced, and the labour-pains are not sufficient to deliver the child; for, the lower part of the uterus may be strongly contracted before the shoulders, and so close to the neck of the child, as to prevent its advancing, even when the head is so loose in the pelvis, that we can sometimes push our fingers all round it: and this is oftentimes the occasion of preventing the head's being delivered when low in the pelvis. The difficulty, when high up, is from the restraint at the brim; and when it passes that, the head is seldom retained in the lower part, unless the patient is weak. In this case, we need not wait, because we are commonly certain of relieving the woman immediately with the forceps, by which you prevent the danger that may happen both to the mother and child, by the head's continuing to lodge there too long. This case should be a caution against breaking the membranes too soon, because the uterus may contract too forcibly and too long before the shoulders; when the head in this case is advanced one third or half way on the outside of the os externum, if the pains are strong, this last inconvenience is frequently remedied by introducing your two fingers into the rectum, as formerly directed: by these rules, delivery may (for the most part) be performed with ease and safety: nevertheless, the head is sometimes so squeezed and locked in the pelvis, and the hairy scalp so much swelled, that it is impracticable to raise up the head so as to come at the ears or os internum; or to distinguish the sutures of the skull, so as to know how the heads presents. In this case, the forceps must be introduced at random, and the uncertainty of the position generally removed by remembering, that in those cases, where the head is squeezed down with great difficulty, the ears are for the most part towards the os pubis and sacrum; and that the forehead seldom turns into the hollow of the sacrum, before the occiput is come down to the lower part of the ischium; and then rises gradually towards the under part of the os pubis, and the perineum and anus are forced down before it, in form of a large tumour.

On such occasions, the woman being laid on her side, if one ear is to the sacrum and the other to the os pubis, the blades of the forceps are to be introduced; and if they meet with any resistance at the points, they must not be forcibly thrust up, lest they pass on the outside of the os uteri, and tear the vagina, which, together with the womb

womb, would be included in the instrument, and pulled along with the head: for this reason, if the blade does not easily pass, let it be withdrawn a little downwards, as before directed, and pushed up again, moving the point close to the head; if the ear obstructs its passage, let the point be brought a little outwards: and by these cautious essays, it will at length pass without further resistance, and ought to be advanced a considerable way, in order to certify the operator that he is not on the outside of the os internum.

When the forceps are fixed, and the operator uncertain which way the forehead lies, let him pull slowly, and move the head with a quarter turn, first to one side and then to the other, until he shall have found the direction in which it comes most easily along.

If at any time we find the forceps begin to slip, we must rest, and push them up again gently: but, if they are like to slide off at a slide, untie the handles, and move them so as to take a firmer hold, fix as before, and deliver. If we are obliged to hold with both hands, the parts may be supported by the firm application of an assistant's hand; for, without such cautious management, they will run a great risk of being lacerated; a misfortune which rarely happens, when the perineum is properly pressed back, and the head leisurely delivered. Sometimes, when the head is brought low down, you may take off the forceps, and help along with your fingers on each side of the coccyx, or in the rectum, as directed in the natural labour.

If the head is low down, the ears are commonly diagonal, or to the sides; and when the head is brought down one third, or one half, through the os externum, the operator can then certify himself, whether the forehead is turned to the coccyx or os pubis, by feeling with his finger for the back-part of the neck or ear, betwixt the os pubis and the head; and then move the head as above directed.

Let him try to alter with his hand every bad position of the head; and if it be detained high up in the pelvis, in consequence of the woman's weakness, the rigidity of the parts, the circumvolutions or shortness of the funis, or the contraction of the uterus over the shoulders of the child, the forceps will frequently succeed when the fetus cannot be turned: but, if the head is large, or the pelvis narrow, the child is seldom saved either by turning or using the forceps, until the head shall be farther advanced. And here it will not be amiss to observe, that the blades of the forceps ought to be new covered with stripes of waxed leather after they shall have been used, especially in delivering a woman suspected of having an infectious distemper.

The signs of a Dead Child.

WHEN the head presents, and cannot be delivered by the labour-pains; when all the common methods have been used without success, the woman being exhausted, and all her efforts vain; and when the child cannot be delivered without such force as will endanger the life of the mother, because the head is too large or the pelvis too narrow; it then becomes absolutely necessary to open the head, and extract with the hand, forceps, or crotchet.

Indeed this last method formerly was the common practice when the child could not be easily turned, and is still in use with those who do not know how to save the child by delivering with the forceps: for this reason, their chief care and study was to distinguish whether the fetus was dead or alive; and as the signs were uncertain, the operation was often delayed until the woman was in the most imminent danger; or when it was performed sooner, the operator was frequently accused of rashness, on the supposition that the child might in time have been delivered alive by the labour-pains: perhaps he was sometimes conscious to himself of the justice of this imputation, although what he had done was with an upright intention.

The signs of a dead fetus were, first, the child's ceasing to move and stir in the uterus. Secondly, The evacuation of meconium, though the breech is not pressed into the pelvis. Thirdly, No perceivable pulsation at the fontanelle and temporal arteries. Fourthly, A large swelling or tumour of the hairy scalp. Fifthly, An uncommon laxity of the bones of the cranium. Sixthly, The discharge of a fetid ichor from the vagina, the effluvia of which surround the woman and gave rise to the opinion that her breath conveyed a mortified smell. Seventhly, Want of motion in the tongue, when the face presents. Eighthly, No perceivable pulsation in the arteries of the funis umbilicalis, when it falls down below the head; nor at the wrist when the arm presents; and no motion of the fingers. Ninthly, The pale and livid countenance of the woman. Tenthly, A collapsing and flaccidity of the breast. Eleventhly, A coldness felt in the abdomen, and weight, from the child's falling like a heavy ball to the side on which she lies. Twelfthly, A separation of the hairy scalp on the slightest touch, and a distinct perception of the bare bones.

All or most of these signs are dubious and uncertain, except the last, which can only be observed after the fetus hath been dead several days. One may also certainly pronounce the child's death; if no pulsation hath been felt in the navel string for the space of twenty or thirty minutes; but the same certainty is not to be acquired from the arm, unless the skin can be stripped off with ease.

When the CROTCHET is to be used.

MIDWIFERY is now so much improved, that the necessity of destroying the child does not occur so often as formerly: indeed it never should be done, except when it is impossible to turn, or to deliver with the forceps; and this is seldom the case but when the pelvis is too narrow, or the head too large to pass, and therefore rests above the brim: for this reason, it is not so necessary for the operator to puzzle himself about dubious signs; because in these two cases, there is no room for hesitation: for if the woman cannot possibly be delivered in any other way, and is in imminent danger of her life, the best practice is undoubtedly to have recourse to that method which alone can be used for her preservation, namely, to diminish the bulk of the head.

In this case, instead of destroying, you are really saving a life; for, if the operation be delayed, both mother and child are lost.

The method of using the Scissors, blunt Hook, and CROTCHET.

WHEN the head presents, and such is the case that the child can neither be delivered by turning, nor extracted with the forceps, and it is absolutely necessary to deliver the woman to save her life, this operation must then be performed in the following manner.

The operator must be provided with a pair of curved crotchets, made according to the improvements upon those proposed by Mefnard, together with a pair of scissors about nine inches long, with rests near the middle of the blades, and the blunt hook.

Of the Woman's Posture.

THE patient ought to be laid on her back or side in the same position directed in the use of the forceps; the operator must be seated on a low chair, and the instruments concealed and disposed in the same manner, and for the same reason mentioned in treating of the forceps. The parts of the woman have already, in all likelihood, been sufficiently dilated by his endeavours to turn or deliver with the forceps; or if no efforts of that kind have been used, because by the touch he had learned that no such endeavours would succeed, as in the case of a large hydrocephalus, when the bones of the cranium are often separated at a great distance from each other; or upon perceiving that the pelvis was extremely narrow: If, upon these considerations, he hath made no trials in which the parts were opened, let him gradually dilate the os externum and internum, as formerly directed.

The head is commonly kept down pretty firm, by the strong contraction of the uterus round the child; but should it yield to one side, let it be kept steady by the hand of an assistant, pressing upon the belly of the woman; let him introduce his hand, and press two fingers against one of the sutures of the cranium; then take out his scissors from the place in which they were deposited, and guiding them by the hand and fingers till they reach the hairy scalp, push them gradually into it, until their progress is stopped by the rests.

If the head slips aside, in such a manner, as that they cannot be pushed into the skull at the future, they will make their way through the solid bones, if they are moved in a semicircular turn, like the motion of boring, and this method continued till you find the point firmly fixed; for, if this is not observed, the points slide along the bones.

The scissors ought to be so sharp at the points, as to penetrate the integuments and bones when pushed with a moderate force; but not so keen as to cut the operator's fingers, or the vagina in introducing them.

The scissors being thus forced into the brain, as far as the rests at the middle of the blades, let them be kept firm in that situation; and the hand that was in the vagina being withdrawn, the operator must take hold of the handles with each hand, and pull them asunder, that the blades may dilate and make a large opening in the skull; then they must be shut, turned, and again pulled asunder, so as to make the incision crucial; by which means the opening will be enlarged, and sufficient room made for the introduction of the fingers: let them be af-

terwards closed, and introduced even beyond the rests; when they must again be opened, and turned half round from side to side, until the structure of the brain is so effectually destroyed, that it can be evacuated with ease. This operation being performed, let the scissors be shut and withdrawn; but, if this instrument will not answer the last purpose, the business may be done by introducing the crotchet within the opening of the skull. The brain being thus destroyed, and the instrument withdrawn, let him introduce his right hand into the vagina, and two fingers into the opening which hath been made, that if any sharp splinters of the bones remain, they may be broken off and taken out; left they should injure the woman's vagina, or the operator's own fingers.

If the case be an hydrocephalus, let him fix his fingers on the inside and his thumb on the outside of the opening, and endeavour to pull along the skull in time of a pain; but, if labour is weak, he must desire the woman to assist his endeavours by forcing down; and thus the child is frequently delivered; because, the water being evacuated, the head collapses of course.

But when the pelvis is narrow, the head requires much greater force to be brought along; unless the labour-pains are strong enough to press it down and diminish it, by squeezing out the cerebrum: in this case, let the operator withdraw his fingers from the opening, and, sliding them along the head, pass the os uteri; then, with his left hand, taking one of the crotchets from the place of its concealment, introduce it along his right hand, with the point towards the child's head, and fix it above the chin in the mouth, back part of the neck, or above the ears, or in any place where it will take firm hold: having fixed the instrument, let him withdraw his right hand, and with it take hold on the end or handle of the crotchet; then introduce his left to seize the bones at the opening of the skull (as above directed) that the head may be kept steady, and pull along with both hands.

If the head is still detained by the uncommon narrowness of the pelvis, let him introduce his left hand along the opposite side, in order to guide the other crotchet; which being also applied and locked or joined with its fellow, in the manner of the forceps, he must pull with sufficient force, moving from side to side, and as it advances, turn the fore head into the hollow of the sacrum, and extract as with the forceps, humouring the shape of the head and pelvis during the operation, which ought to be performed slowly, with great judgment and caution; and from hence it appears absolutely necessary to know how the head presents, in order to judge how the crotchet must be fixed, and the head brought along to the best advantage.

If, when the head is delivered in this manner, the body cannot be extracted, on account of its being much swelled, of a monstrous size, or (which is most commonly the case) the narrowness of the pelvis; let him desist from pulling, lest the head should be separated from the body, and introducing one hand so as to reach with his fingers to the shoulder-blades or breast, conduct along it one of the crotchets, with the point towards the fœtus, and fix it with a firm application; then withdrawing his hand, employ it in pulling the crotchet, while the other

is exerted in the same manner upon the head and neck of the child : if the instrument begins to lose its hold, he must push it farther up, and fixing it again, repeat his efforts, applying it still higher and higher, until the body is extracted.

OF PRETERNATURAL LABOURS.

PRETERNATURAL labour happens, when, instead of the head, some other part of the body presents to the os uteri. Preternatural labours are more or less difficult according to the presentation of the child, and the contraction of the uterus round its body. The nearer the head and shoulders are the os internum or lower part of the uterus, the more difficult is the case; whereas, when the head is towards the fundus, and the feet or breech near the os internum, it is more easy to turn and deliver.

To begin with the easiest of these first, it may be proper to divide them into three classes. First, how to manage when the feet, breech, or lower parts present. Secondly, how to behave in violent floodings; and, when the child presents wrong before the membranes are broke, how to save the waters in the uterus, that the fœtus may be the more easily turned : and what method to follow even after the membranes are broke, when all the waters are not evacuated. Thirdly, how to deliver when the uterus is strongly contracted, the child presenting either with the fore or back parts; and lying in a circular form, or with the shoulders, breast, neck, face, ear, or vertex, and lying in a longish form, with the feet and breech towards the fundus of the womb, which is contracted like a long sheath, close to the body of the fœtus; and when the fore-parts of the child lie towards the side, fundus, fore or back part of the uterus.

The first class of PRETERNATURAL LABOURS. When the feet, breech, or lower parts of the fœtus present, and the head, shoulders, and upper parts are towards the fundus.

THESE, for the most part, are accounted the easiest, even although the uterus should be strongly contracted round the body of the child, and all the waters discharged.

If the knees or feet of the child present to the os internum, which is not yet sufficiently dilated to allow them and the body to come farther down; or, if the woman is weak, wore out with long labour, or endangered by a flooding; let the operator introduce his hand into the vagina, push up and stretch the os uteri, and bring along the feet; which being extracted, let him wrap a linen cloth round them, and pull until the breech appears on the outside of the os externum : if the face or fore-part of the fœtus is already towards the back of the uterus, let him persist in pulling in the same direction; but, if they are towards the os pubis, or to one side, they must be turned to the back-part of the uterus; and as the head does not move round equal with the body, he must make allowance for the difference in turning, by bringing the last one quarter farther than the place at which the head is to be placed; so that the face or forehead which was towards one of the groins will be forced to the side of the sacrum, where it joins with the ischium. This quar-

ter turn of the body must be again undone, without affecting the position of the head; a cloth may be wrapped round the breech, for the convenience of holding it more firmly; then, placing a thumb along each side of the spine, and with his fingers grasping the belly, let him pull along the body from side to side, with more or less force, according to the resistance: when the child is delivered as far as the shoulders, let him slide his hand flattened (suppose the right, if she lies on her back) between its breast and the perineum, coccyx, and sacrum of the woman, and introduce the fore or middle finger (or both, if necessary) into the mouth of the fœtus; by which means, the chin will be pulled to the breast, and the forehead into the hollow of the sacrum. And this expedient will also raise upwards the hindhead, which rests at the os pubis.

When the forehead is come so low as to protrude the perineum, if the woman lies on her back, let the operator stand up, and pull the body and head of the child upwards, bringing the forehead with an half-round turn from the under part of the os externum, which will thus be defended from laceration. The application of the fingers in the child's mouth will contribute to bring the head out in this manner, prevent the os externum from hitching on the chin, help along the head, and guard the neck from being overstrained; a misfortune which would infallibly happen, if the forehead should be detained at the upper part of the sacrum: nor is there any great force required to obviate this inconvenience, or the least danger of hurting the mouth, if the head is not large: for, if the head cannot be brought along with moderate force, and the operator is afraid of injuring or over-training the lower jaw, let him push his fingers farther up, and press on each side of the nose, or on the inferior edges of the sockets of the eyes. If the legs are come out, and the breech pulled into the vagina, there is no occasion for pushing up to open, but only to pull along and manage as above directed; still remembering to raise the forehead slowly from the perineum, which may be pressed back with the fingers of his other hand.

In the case of a narrow pelvis, or large head, which cannot be brought along without the risk of over-training the neck, let him slide up his fingers and hand into the vagina, and bring down one of the child's arms, at the same time pulling the body to the contrary side, by which means the shoulder will be brought lower down: let him run his fingers along the arm, until they reach the elbow, which must be pulled downwards with an half round turn to the other side, below the breast. This must not be done with a jerk, but slowly and cautiously, in order to prevent the dislocation, bending, or breaking of the child's arm.

Let him again guide his fingers into the child's mouth, and try if the head will come along: if this will not succeed, let the body be pulled to the other side, so as to bring down the other shoulder; then slide up his left hand, and, extracting the other arm, endeavour to deliver the head. If one finger of his right hand be fixed in the child's mouth, let the body rest on that arm: let him place the left hand above the shoulders, and put a finger on each side of the neck: if the forehead is towards one side

side at the upper part of the pelvis, let him pull it lower down, and gradually turn it into the hollow of the sacrum; then stand up, and, in pulling, raise the body, so as to bring out the head in an half-round turn, as above directed.

When the forehead is hindered from coming down into the lower part of the sacrum by an uncommon shape of the head or pelvis, and we cannot extract it by bringing it out with an half-round turn at the os pubis, we must try to make this turn in the contrary direction; and instead of introducing our fingers into the child's mouth, let the breast of it rest on the palm of your left hand, (the woman being on her back,) and placing the right on its shoulders, with the fingers on each side of the neck, press it downwards to the perineum. In consequence of this pressure, the face and chin being within the perineum, will move more upwards, and the head come out with an half-round turn from below the os pubis: for the centre of motion is now where the fore-part of the neck presses at the perineum; whereas, in the other method, the back part of the neck is against the lower part of the os pubis, on which the head turns.

If the forehead is not turned to one side, but sticks at the upper part of the sacrum, especially when the pelvis is narrow; let him endeavour, with his finger in the mouth, to turn it to one side of the jetting in of the sacrum, because the pelvis is wider at the sides of the brim, and bring it along as before.

If one of the child's arms, instead of being placed along the sides of the head, is turned in between the face and sacrum, or between the hindhead and os pubis, the same difficulty of extracting occurs as in a large head or narrow pelvis; and this position frequently ensues, when the fore-parts of the child's body are turned from the os pubis down to the sacrum: if they are turned to the left side of the woman, the left hand and arm are commonly brought in before the face, and *vice versa*; but, in these cases, the elbow is, for the most part, easily come at, because it is low down in the vagina, and then there is a necessity for bringing down one or both arms before the head can be delivered: from whence we may conclude, that those authors are sometimes in the wrong, who expressly forbid us to pull down the arms. Indeed, if the pelvis is not narrow, nor the head very large, and the arms lie along the sides of the head, there is seldom occasion to pull them down; because, the pelvis is widest at the sides, and the membranes and ligaments that fill up the space betwixt the sacrum and ilchia yield to the pressure, and make room for the passage of the head: but when they are squeezed between the head and the sacrum, ilchia, or ossa pubis, and the head sticks in the pelvis, they certainly ought to be brought down, or even when the head comes along with difficulty. Neither is the alleged contraction of the os internum round the neck of the child so frequent as hath been imagined; because, for the most part, the contraction embraces the head and not the neck: but, should the neck alone suffer, that inconvenience may be removed by introducing the hand into the vagina, and a finger or two into the child's mouth, or on each side of the nose: by which means also a sufficient dilatation will be preserved in the os externum,

which frequently contracts on the neck, as soon as the arms are brought out.

The diameter, from the face or forehead to the vertex, being greater than that from the forehead to the back part of the hindhead or neck, when the hindhead rests at the os pubis, and the forehead at the upper part of the sacrum, the head can seldom be brought down, until the operator, by introducing a finger into the mouth, moves the same to the side, brings the chin to the breast, and the forehead into the hollow of the sacrum; by which means, the hindhead is raised, and allowed to come along with greater ease: and in pulling, half the force only is applied to the neck, the other half being exerted upon the head, by the finger which is fixed in the mouth; so that the forehead is more easily brought out, by pulling upwards, with the half-round turn from the perineum. When the operator, with his fingers in the child's mouth, cannot pull down the forehead into the hollow of the sacrum, let him push the fore-finger of his left hand betwixt the neck and os pubis, in order to raise the hindhead upwards; which being done, the forehead will come down with less difficulty, especially if he pushes up and pulls down at the same time, or alternately.

If it be discovered by the touch, that the breech presents, that the membranes are not yet broke, the woman in no danger, the os internum not yet sufficiently dilated, and the labour-pains strong; the midwife ought to wait until the membranes, with the waters, are pushed farther down, as in the natural labour: for, as they come down through the os uteri into the vagina, they stretch open the parts contained in the pelvis; and the bulk within the uterus being diminished, it contracts and comes in contact with the body of the child; so that the breech is pushed along by the mechanical force of the abdominal muscles operating upon the womb.

The same consequence will follow even although the membranes are broke; for the waters lubricate the parts as they flow off; and the breech, if not too large, or the pelvis narrow, is pushed down. In this case, when the nates present equal and fair to the os uteri, so it is also reasonable to conclude, that when the breech presents, it lies in the same manner, but that the fore-parts of the child are rather turned backwards to one side of the vertebæ of the loins: in this position, one hip will present, and the other rest on the os pubis; but, when forced along with pains, the last will be gradually moved more and more to the groin of that side, and from thence slip down at the side of the basin: the lower at the same time will be forced to the other, and the hollow betwixt the thighs will rest upon the jetting in of the os sacrum, and come down in that manner; the thighs on each side, and the back and round part of the breech passing in below the arch of the os pubis, which is the best position: but if the back of the child is tilted backwards, then it will be forced down in the contrary direction, and come along with more difficulty, *viz.* the thighs to the os pubis, and back to the sacrum; when it is come down to the middle or lower part of the pelvis, let the operator introduce the fore-finger of each hand, along the outside, to the groins, and, taking hold, pull gently along during a strong pain.

If the os externum is so contracted, that he cannot
take

take sufficient hold, let it be opened slowly, so as to allow his hands to be pushed up with ease; when he has infirmated a finger or two in each groin, let him place his thumbs on the thighs, if they are towards the *os pubis*, so as to obtain a firm hold; then pull along from side to side, and, if the back of the child is to the *os pubis*, continue to assist in this manner, until the body and head are delivered: the legs being commonly stretched up along the belly and breast, when the child is extracted as far as the shoulders, they come out of themselves, or are easily brought down; but, if the belly of the child is turned to one side, or to the *os pubis*, in that case, when the breech is delivered, he ought to turn the belly down to the sacrum, and the back to the *os pubis*; and that the face may be also turned to the back of the mother, let him remember the quarter extraordinary, which must be again reversed, and then he may pull along and deliver.

If the body cannot be turned until the thighs and legs are brought down, either on account of the bulk, or because the hold on the breech is not sufficient, let him continue to pull along, until the hams appear on the outside of the *os externum*; then seize one of the knees with his finger and thumb, and extract that leg; and let the other be brought down in the same manner. If he attempts to pull out the legs, before the hams arrive at this place, the thighs are always in danger of being bent or broke. When the legs are delivered, let him wrap a cloth round the breech of the child, and as the body was pulled down almost as far as the breast, before the legs could be brought out, it must be pushed up again to the navel, or above it; because, without this precaution, the shoulders would be so much engaged in the pelvis, that it would be impracticable to make the motions formerly directed, so as to turn the face to the back of the mother: whereas, when the body is pushed up, those turns can be effected with greater ease, because the belly being in the pelvis, it yields easier to the form of the basin. When the face is turned properly down, let him proceed to deliver, as above directed.

If the breech is detained above the pelvis, either by its uncommon magnitude, or the narrowness of the basin; or if one of the nates is pushed in, while the other rests above the *os pubis*, sacrum, or to either side; if the woman is low and weak, the pains lingering and insufficient to force the child along; or if she is in danger from a violent flooding: in any of these cases, let him (during every pain) gradually open first the *os externum*, and then the *os internum*, with his fingers and hand. Having thus gained admission, let him push up the breech to the fore or back part, or to one side of the uterus, that his hand and arm may have room to slide along the fore-parts or belly of the child, so as to feel the thighs, that will direct him to the legs, which must be brought down with his fingers, while, at the same time, he pushes up the hams with his thumb, that in case the legs lie straight up, they may be extracted with more ease by the flexion of the knee, and run the less risk of being bent, broke, or overstrained: for, if they are folded downward, they are the more easily brought out.

If the breech be strongly pressed into the upper part of the pelvis, let him also push it upwards and to one side,

that his hand and arm may have free passage; for the higher the breech is raised out of his way, he will be at more freedom to extract the legs.

If both legs cannot be easily brought down, he may safely deliver with one, of which taking hold with a linen cloth wrapped round it, let him slide up his other hand into the vagina, and a finger or two into the outside of the groin which is bent: by these means, the hip will come down the easier, and the leg, which is already extracted, will not be overstrained by sustaining the whole force of pulling the body along.

If the legs lie towards the left side of the woman, who is laid on her back, the right hand must be introduced into the uterus; if they lie to her right side, the left hand will better answer the purpose; and if they are towards her back or belly, either hand may be indifferently used.

In all cases where the breech presents, the safest practice is always to push up and bring down the legs, provided the *os uteri* is sufficiently dilated, and the waters not wholly discharged. If the waters are evacuated, the uterus strongly contracted around the child, the breech low, so as that it cannot be returned, or so small as to come easily along, we ought then to deliver it accordingly; but, if so large as neither to be pushed up or brought along with the assistance of the fingers, let the operator introduce the curved handle of the blunt crotchet into one of the groins, his fingers into the other, and pull very cautiously, in order to prevent a fracture or dislocation of the thigh bone, which might otherwise happen from the use of this instrument, the blunt point of which must be sufficiently past the groin. A fillet may also be used for the same purpose.

In the foregoing cases the woman was supposed to be laid on her back, her legs supported, and breech to the bed-side; this being generally the best position for delivering the body and head: indeed, when the child is small, she may lie on her side, and the same methods be used in delivering, provided the operator still remembers that in this position the ilium and ischium of one side are down, and the others up. Besides, when the breech is pushed up, in order to bring down the legs, if they lie forewards towards the fore part of the uterus, and the belly is pendulous, he can reach them with the greatest ease when she lies on one side, or, if the resistance is very great, turn her to her knees and elbows; but, when the legs are delivered, if the child is large, or the pelvis narrow, she ought to be turned upon her back, because the body and head can be better and safer delivered by pulling up and down; and in that posture she is also kept more firm, and her thighs less in the operator's way, than when she lies upon her side. See Plate CXIII. fig. 1. and 2.

The second class of PRENATURAL LABOURS.

WHEN the membranes are broke, but the face, shoulder, or some other part of the child, being pushed into the pelvis, locks up the *os internum*, so as that a small quantity of the waters hath been discharged, the uterus is kept from contracting strongly round the child, which is therefore more easily turned than it possibly can be when they are all gone:

When

When, before the membranes are broke, the child is felt through them, presenting wrong, and at the same time the pains push them down so as to dilate the os internum more or less :

When the woman, at any time in the four last months, is seized with a violent flooding that cannot be restrained, and unless speedily delivered must lose her life ; if labour-pains cannot be brought on by stretching the parts, delivery must be forced ; but, if she is in labour, and the membranes have been pushed down with the waters, they may be broke ; by which means, the flooding is frequently diminished, and the child delivered by the labour-pains.

In these three different cases, if we can prevent the strong contraction of the uterus by keeping up the waters, we can also for the most part turn the child with great ease, even in the very worst positions.

In the first case, let the operator slowly introduce his hand into the vagina, and his fingers between that part of the child which is pushed down, and the os internum : if in so doing he perceives some of the waters coming along, he must run up his hand as quick as possible into the uterus, betwixt the inside of the membranes and the child's body ; the lower part of his arm will then fill up the os externum like a plug, so that no more of the waters can pass ; let him turn the child with its head and shoulders up to the fundus, the breech down to the lower part of the uterus, and the fore parts towards the mother's back ; let the hand be pushed no farther up than the middle of the child's body, because, if it is advanced as high as the fundus, it must be withdrawn lower, before the child can be turned ; and by these means the waters will be discharged, and the uterus of consequence contract so as to render the turning more difficult.

In the second case, when the membranes are not broke, and we are certain that the child does not present fair ; if the os internum is not sufficiently dilated, and the woman is in no danger, we may let the labour go on, until the parts are more stretched ; lubricating and extending the os externum, by degrees, during every pain. Then introducing one hand into the vagina, we insinuate it in a flattened form, within the os internum, and push up between the membranes and the uterus, as far as the middle of the womb : having thus obtained admission, we break the membranes by grasping and squeezing them with our fingers, slide our hand within them, without moving the arm lower down, then turn and deliver as formerly directed ; but if, in any of these cases, you find the head is large or the pelvis narrow, bring down the head into the natural position, and assist as directed in lingering or laborious cases.

If the woman (in the third case) is attacked with a violent flooding, occasioned by a separation of all or any part of the placenta from the uterus, during the last four months of pregnancy, and every method has in vain been tried to lessen and restrain the discharge, the operator ought to pronounce the case dangerous, and prudently declare to the relations of the patient, that unless she is speedily delivered, both she and the child must perish, observing at the same time, that by immediate delivery they may both be saved : let him also desire the assistance and advice of some person eminent in the profession, for

the satisfaction of her friends, and the support of his own reputation. Where there are no labour-pains, and the mouth of the womb is not dilated, it is sometimes very difficult to deliver, more especially if the os internum is not a little lax, but feels rigid.

If the os uteri is so much contracted, that the finger cannot be introduced, some authors have recommended a dilator, by which it may be gradually opened so as to admit a finger or two. Doubtless, some cases may happen, in which this may be necessary. If in stretching the os internum, labour-pains are brought on, let the operator slowly proceed and encourage them : when the mouth of the womb is opened, if the head presents and the pains are strong, by breaking the membranes the flooding will be diminished ; but, if the floods to such a degree as to be in danger of her life, and the dilatation does not bring on labour, at least not enough for the occasion, she must be immediately delivered in the following manner : but in the first place let her friends be apprized of the danger, and the operator beware of promising to save either mother or child.

The operator having performed his duty in making the friends acquainted with the situation of the case, must gently open the os externum, by introducing his fingers gradually, turning them half round and pushing upward ; then forming them, with the thumb, into the figure of a wedge or cone, continue to dilate slowly and by intervals, until his hand is admitted into the vagina : having thus far gained his point, let him insinuate, in the same slow cautious manner, first one, then two fingers, into the os internum, which may be dilated so as to admit the other two and the thumb in the same conical form, which will gradually make way for sliding the hand along between the outside of the membranes and inside of the uterus ; then he must manage as directed in the second case : If, upon sliding up his hand upon the outside of the membranes, he feels the placenta adhering to that side of the womb, he must either withdraw that hand, and introduce the other on the opposite side, or break through the membranes at the lower edge of the placenta.

The greatest danger in this case frequently proceeds from the sudden emptying of the uterus and belly ; for when labour comes on of itself, or is brought on in a regular manner, and the membranes are broke, the flooding is gradually diminished, and first the child, then the placenta, is delivered by the pains ; so that the pressure or resistance is not all at once removed from the belly and uterus of the woman, which have time to contract by degrees ; consequently, those fainting fits and convulsions are prevented which often proceed from a sudden removal of that compression under which the circulation was performed.

The younger the woman is with child, the greater is the difficulty in opening the os internum ; and more so in the first child, especially if she is past the age of thirty-five.

We should never refuse to deliver in these dangerous cases, even although the patient seems expiring : for, immediately after delivery, the uterus contracts ; the mouths of the vessels are shut up, so that the flooding ceases ; and she may recover, if she lives five or six hours

after the operation, and can be supported by frequent draughts of broth, jelly, caudle, weak cordial, and anodyne medicines, which maintain the circulation, and gradually fill the empty vessels.

If, in time of flooding, the is seized with labour-pains, or if, by every now and then stretching with your fingers the os internum, you bring on labour, by which either the membranes or head of the child is pushed down, and opens the os internum, the membranes ought to be broke; so that some of the waters being discharged, the uterus may contract and squeeze down the foetus. This may be done sooner in those women who have had children formerly. If, notwithstanding this expedient, the flooding still continues, and the child is not like to be soon delivered, it must be turned immediately; or, if the head is in the pelvis, delivered with the forceps: but, if neither of these two methods will succeed, on account of the narrowness of the pelvis, or the bigness of the head, this last must be opened and delivered with the crotchet. In all these cases, let the parts be dilated slowly and by intervals, in order to prevent laceration. See Plate CXI. fig. 4. 5. 6.

The third class of PRETERNATURAL LABOURS.

We have already observed, that the principal difficulties in turning children and bringing them by the feet, proceeded from the contraction of the uterus and bad position of the foetus. If the child lies in a round form, whether the fore-parts are towards the os internum, or up to the fundus uteri, we can, for the most part, move it with the hand, so as to turn the head and shoulders to the upper part, and the breech and legs downwards; but if the child lies lengthways, the womb being contracted around it, like a long sheath, the task is more difficult; especially, if the head and shoulders of the child are down at the lowest part of the uterus, with the breech and feet turned up to the fundus.

The hand of the operator being introduced into the uterus, if he finds the breech below the head and shoulders, let him search for the legs, and bring them down: but if the breech be higher than the upper parts of the child, or equal with them, he must try to turn the head and shoulders to the fundus, and the breech downwards, by pushing up the fist, and pulling down the left; then proceed with delivery as before directed. This is commonly executed with ease, provided some part of the waters still remain in the uterus; but, if the woman has been long in labour, and the waters discharged, the contraction of the womb is so strong, that the child cannot be turned without the exertion of great force frequently repeated. In this case, the easiest method both for the patient and operator, is to push up the hand gradually on that side to which the legs and thighs are turned; and even after he has reached them, if they are not very high up, let him advance his hand as far as the fundus uteri; he will thus remove the greatest obstacle, by enlarging the cavity of the womb, so as more easily to feel and bring down the legs: then he may push up and pull down, as we have prescribed above: but, if the head and shoulders still continue to hinder the breech and body from coming along, and the feet cannot be brought so low, as the outside of the

os externum, while they are yet in the vagina he may apply a noose upon one or both; for unless the child is so small that he can turn it round by grasping the body when the head and shoulders are pushed up, and he endeavours to bring down the other part, they will again return to the same place, and retard delivery: whereas, if he gains a firm hold of the feet, either without the os externum, or in the vagina, by means of the noose fixed upon the ancles, he can with the other hand push up the head and shoulder, and be able in that manner to bring down the breech. He must continue this method of pushing up and pulling down, until the head and shoulder are raised to the fundus uteri; for should he leave off too soon, and withdraw his hand, although the child is extracted as far as the breech, the head is sometimes so pressed down and engaged with the body in the passage, that it cannot be brought farther down without being tore along with the crotchet; for the breech and part of the body may block up the passage in such a manner, as that the hand cannot be introduced to raise the head.

Those cases are commonly the easiest in which the fore-parts present, and the child lies in a round or oval form, across the uterus, or diagonally, when the head or breech is above and over the os pubis, with the legs, arms, and navel-string, or one or all of them, at the upper or lower part of the vagina, or on the outside of the os externum. Those are more difficult in which, though the child lies in the same round or contracted form, the back, shoulders, belly, or breast, are over the os internum; because if we cannot move the child round, so as to place the head to the fundus, the legs are brought down with much more difficulty than in the other case: but if the shoulder, breast, neck, ear, face, or crown of the head presents, and the legs and breech are up to the fundus uteri, the case is still more difficult; because, in the other two, the uterus is contracted in a round form, so that the wrong position of the child is more easily altered than in this, when the womb is contracted in a long shape, and sometimes requires vast force to stretch it, so as that the head may be raised to the fundus, and the legs and breech brought down.

The crown of the head is the worst part that can present, because in that case the feet and breech are higher, and the uterus of a longer form than in any other. The presentation of the face is, next to this, attended with the greatest difficulty: but when the neck, shoulder, back, or breast present, the head is turned upwards, and keeps the lower part of the womb distended: so that, upon stretching the upper part, the child's head is more easily raised to the fundus.

When the fore-parts of the child present, if the feet, hands, and navel-string are not detained above the os uteri, some or all of them descend into the vagina, or appear on the outside of the os externum. If one or more of them come down, and the child at the same time lies in a round form across the uterus, let the accoucheur introduce his hand between them and the sacrum: When it is past the os internum, let it rest a little, while he feels with his fingers the position of the foetus: if the head and shoulders lie higher than the breech, he must take hold of the legs and bring them down without the os
internum:

internum : if the breech is detained above the brim of the pelvis, let him slide up the flat of his hand along the buttocks, and pull down the legs with the other hand ; by which method the breech is disengaged and forced into the middle of the pelvis. See Plate CXIII. fig. 3.

In most of those cases where the child is pressed in an oval form, if neither the head or breech present, the head is to one side of the uterus, and the breech to the other ; because it is wider from side to side, than from the back to the fore part ; and if either the head or breech is over the os pubis, the other is turned off to the side : in moving the head or shoulders to the fundus, they are raised with greater ease along the side, than at the back or fore parts, for the same reasons.

If the head and shoulders lie lower down, so as to hinder the breech from coming along, and the legs from being extracted, let him push up the head and shoulders to the fundus, and pull out the legs ; then try to bring in the breech ; and if it still sticks above, because the head and shoulders are again forced down by the contraction of the uterus, he must with one hand take hold of the legs that are now without the os externum, and, sliding the other into the uterus, push the head and shoulders again up to the fundus, while, at the same time, he pulls the legs and breech along with the feet. If the legs cannot be brought farther down than the vagina, because the breech is high up, let him slip a noose over the feet round the ankles, as before observed ; by which he may pull down the lower parts with one hand, while the other is employed in pushing up, as before. By this double purchase, the child may be turned even in the most difficult cases : but the operator, in pulling, must beware of overstraining the ligaments of the joints.

If the legs can be extracted through the os externum, let a single cloth, warmed, be wrapped round them, in order to yield a firm hold to the accoucheur ; but when they can be brought no lower than the neck of the uterus and vagina, he may use one of these following nooses.

Let him take a strong limber fillet, or soft garter half-worn, about one yard and an half in length, and moderately broad and thick ; if thick, an eye may be made at one end of it, by doubling about two inches and sewing it strongly ; and the other end passed through this doubling, in order to make the noose ; which being mounted upon the thumb and fingers of his hand, must be introduced, and gently slipped over the toes and feet of the child so as to embrace the ankles, and thus applied it must be drawn tight with his other hand.

If the foot or feet should be so slippery, that his fingers cannot hold them, and work over the noose at the same time, it must be withdrawn and mounted round his hand or wrist ; with which hand, when introduced, he may take firm hold on both feet, if they are as far down as the vagina ; then with the fingers of his other hand, he can slide the noose along the hand and fingers that hold the feet, and fix it round the ankle : but if one foot remains within the uterus, the fingers of his other hand cannot push up the noose far enough to slide it over the ankle ; so that he must have recourse to a director, like that for polyposes, mounted with the noose, which will push it along the hand and fingers that hold the foot. The

noose being thus slipped over the fingers upon the ankle, he must pull the extremity of the fillet which hath passed the eye at the upper end of the director, and after it is close drawn, bring down the instrument.

If the fillet or garter is too narrow or thin, let it be doubled in the middle, and the noose made by passing the two ends through the doubling.

When the belly presents, and the head, shoulders, breech, thighs, and legs, are turned up over the back to the fundus uteri ; when the back presents, and all these parts are upwards ; when the side presents, with the head, shoulders, breech, thighs and legs turned to the side, back, or fore part of the uterus : In all these cases, when the child is pressed into a round, or (more properly) an oval figure, it may be, for the most part, moved round, with one hand introduced into the uterus, the head and shoulders pushed to the fundus, and the legs and breech to the os internum ; which being effected, the legs are easily brought down. See Plate CXIII. fig. 4. But these cases are more or less difficult as the feet are farther up, or lower down, because the business is to bring them downwards.

When the breast, shoulders, neck, ear, or face present to the os internum, the breech, thighs, and legs being towards the fundus, with the fore parts of the fœtus turned either to the side, back, or fore-part of the woman's belly ; and the whole lying in a longish form, the uterus being closely contracted around its body like a sheath ; let the accoucheur introduce his hand into the vagina, and open the os internum by pushing up the fingers and hand flattened between the parts that present and the inside of the membranes ; and rest his hand in that situation, until he can distinguish how the child lies, and form a right judgment how to turn and deliver ; for, if these circumstances are not maturely considered, he will begin to work in a confused manner, fatigue himself and the patient, and find great difficulty in turning and extracting the child.

If the feet and legs of the fœtus lie towards the back, sides, or fundus uteri, the woman ought to be laid on her back, with her breech raised and brought a little over the bed, as formerly observed ; because, in that position he can more easily reach the feet than in any other.

If they lie towards the fore-part of the uterus, especially when the belly is pendulous, she ought to lie upon her side ; because in the other posture, it is often difficult to turn the hand up to the fore-part of the womb ; whereas, if she is laid on the left side, the right hand may be introduced at the upper part and left side of the brim of the pelvis, where it is widest, and then along the fore-part of the uterus, by which means the feet are more easily come at. If it is more convenient for the accoucheur to use his left hand, the patient may be turned on her right side. The only inconvenience attending these positions, is, that the woman cannot be kept so firm and steady, but will be apt to toss about and shrink from the operators ; and besides, there may be a necessity for turning her upon her back, after the body is delivered, before he can extract the head, especially if it be large, or the pelvis narrow.

The situation of the child being known, and the position

of the mother adjusted, let the proper hand be introduced, and the first effort always made in pushing the presenting part up towards the fundus, either along the sides, back, or fore part of the uterus, as is most convenient. If this endeavour succeeds, and the breech, thighs, or legs come down, the body may be delivered with ease: but if the head, shoulder, breast, or neck present, the other parts of the body being stretched up lengthways, and the uterus so strongly contracted around the child, that the presenting part cannot be raised up, or, though pushed upwards, immediately returns before the legs can be properly seized or brought down; the operator ought, in that case, to force up his hand slowly and gradually between the uterus and the child: if the resistance is great, let him rest a little, between whiles, in order to save the strength of his hand and arm, and then proceed with his efforts until he shall advance his hand as far as the feet; for the higher his hand is pushed, the more will the uterus be stretched, and the more room granted for bringing the legs along: and if, in pushing up his hand, the fingers should be entangled in the navel-string or one of the arms, let him bring it a little lower, and pass it up again on the outside of such incumbrance.

The hand being advanced as high as the fundus, let him, after some pause, feel for the breech, slide his fingers along the thighs in search of the legs and feet; of which taking hold with his whole hand, if possible, let him bring them down either in a straight line or with a half turn: or should the contraction of the uterus be so strong, that he cannot take hold of them in that manner, let him seize one or both ancles between his fingers, and pull them along; but if he cannot bring them down to the lower part of the uterus, so as to apply the noose, he must try again to push up the body, in order still more to stretch the uterus, and obtain freer scope to bring them down lower: then he may apply the noose, and turn the child as above directed, until the head and shoulders are raised up to the fundus, and the feet and breech delivered.

If one leg only can be brought down, the child being turned, and that member extracted through the os externum, let the accoucher slide his hand up to fetch the other; but, if this cannot be done, he must fix a finger on the outside of the groin of that thigh which is folded up along the belly, and bring along that buttock, as in the breech case, while he pulls with his other hand at the other leg; and the body being thus advanced, deliver as before directed.

When the shoulder presents, and the arm lies double in the vagina, let him push them both up; but, if this cannot be done, and the hand is prevented from passing along, he must bring down the arm, and hold it with one hand, while the other is introduced; then let go and push up the shoulder, and as the child is turned, and the feet brought down, the arm will for the most part return into the uterus: but if the arm that is come down, be so much swelled, that it is impracticable to introduce the hand, so as to turn and deliver the child, he must separate it at the joint of the shoulder, if it be so low down; or at the elbow, if he cannot reach the shoulder. If the limb be much mortified, it may be twisted off; otherwise, it may be snipt and separated with the scissors.

If the shoulder, by the imprudence and ignorance of the unskilful, who pull, in expectation of delivering in that way, is forced into the vagina, and part of it appears on the outside of the os externum, a vast force is required to return it into the uterus; because, in this case, the shoulder, part of the ribs, breast, and side, are already pulled out of the uterus, which must be extended so as not only to receive them again, but also to admit the hand and arm of the accoucher. If this distension cannot possibly be effected, he must fix a crochcet above the sternum, and turn the child by pushing up the shoulder and pulling down with the crochcet; or slide his fingers to the neck of the child, and with the scissors divide the head from the body; then deliver first the separated head, or bring along the body by pulling at the arm, or, if need be, with the assistance of the crochcet.

When the forehead, face, or ear presents, and cannot be altered with the hand into the natural position; or is not advanced to the os externum, so as that we can assist with the forceps; the head must be returned, and the child delivered by the feet: but if this cannot be done, and the woman is in imminent danger, recourse must be had to the crochcet.

If the navel-string comes down by the child's head, and the pulsation is felt in the arteries, there is a necessity for turning without loss of time; for unless the head advances fast, and the delivery is quick, the circulation in the vessels will be entirely obstructed, and the child consequently perish. If the head is low in the pelvis, the forceps may be successfully used.

No doubt, if the pelvis is very narrow, or the head too large, it would be wrong to turn: in that case, we ought to try if we can possibly raise the head, so as to reduce the funis above it, and after that let the labour go on: but, if the waters are all gone, and a large portion of the funis falls down, it is impossible to raise it, so as to keep it up, even although we could easily raise the head; because, as one part of the funis is pushed up with the fingers, another part falls down, and evades the reduction; and to raise it up to the side, and not above the head, will be to no purpose; when a little only jets down at the side of the head, our endeavours will, for the most part, be successful.

The ancients, as well as some of the moderns, advise, in all cases when the upper parts, such as the shoulders, breast, neck, face, or ear of the child present, to push them upwards, and bring in the head as in the natural way; observing, that the fetus ought never to be delivered by the feet, except in the presentation of the lower parts, such as the small of the back, belly, side, breech, or legs. Were it practicable at all times to bring the head into the right position, a great deal of fatigue would be saved to the operator, much pain to the woman, and imminent danger to the child: he therefore ought to attempt this method, and may succeed when he is called before the membranes are broke, and feels, by the touch, that the face, ear, or any of this upper parts, presents; in that case, let him open the os externum slowly during every pain, and when the os internum is sufficiently dilated by the descent of the waters and membranes, let him introduce his hand into the uterus, as before directed, betwixt the womb and the membranes, which must be broke;

broke; and if he finds the head so large, or the pelvis so narrow, that it will be difficult to save the child; provided the woman is vigorous and has strong pains, he may with little difficulty bring in the crown of the head, then withdraw his hand; and if the pains return and continue, the child has a good chance to be delivered alive. Even after the membranes are broke, if the presenting part hath so locked up the os internum, as to detain some portion of the waters (a circumstance easily known in pushing up the part that presents,) he may run up his hand speedily to keep them from being discharged, and act in the same manner: but if the child is not large, nor the pelvis narrow, it were pity, while his hand is in the uterus, to desist from turning the child and bringing it by the feet; because, in that case, he may be pretty certain of saving it. Besides, after the head is brought into the right position, should the pains go off entirely, (and this frequently happens,) or a flooding come on, in consequence of the force which hath been exerted, he will find great difficulty in turning after the waters have been discharged; for, it is harder to turn when the vertex presents, than in any other position; whereas, in the case of a large head or narrow pelvis, when the head is forced down by the labour-pains, and will not farther advance, the child may be saved by the forceps; nay, though the pains do not act so as to force it down, to be delivered either by the forceps or in the natural way, the head may be opened and extracted with the crotchet, which is the last resource.

But this necessity seldom occurs, because the cases in which we are most commonly called, are after the membranes have been long broke, the waters discharged, and the uterus strongly contracted around the body of the child, which it confines, as it were, in a mould: so that it is next to impossible to bring the head into the natural position; for this cannot be effected without first pushing up the part that presents, for which purpose great force is required; and as one hand only can be introduced, when the operator endeavours to bring in the head, the pushing force is abated, to allow the pulling force to act; and the parts that hindered the head from presenting are again forced down: besides, the head is so large and slippery, that he can obtain no firm hold. He might, indeed, by introducing a finger into the mouth, lay hold of the under jaw, and bring in the face, provided the shoulder presents; but, instead of amending, this would make the case worse, unless the child be very small: yet, granting the head could be brought into the natural position, the force necessarily exerted for this purpose would produce a flooding, which commonly weakens the patient, and carries off the pains; and after all, he must turn with less advantage: and if that cannot be performed when the head is brought in, he must have recourse to the last and most disagreeable method; whereas when any other part presents, we can always turn the child, and deliver it by the feet. This we cannot promise after the head is brought in; and once the operator's hand is in the uterus, he ought not to run such risks.

The child is often in danger, and sometimes lost, when the breech presents, and is low down in the pelvis, provided the thighs are so strongly pressed against the funis

and belly, as to stop the circulation in the rope; as also when the child is detained by the head, after the body is delivered: in both cases, the danger must be obviated by an expeditious delivery; and if the body is entangled in the navel-string, it must be disengaged as well as possible, especially when the funis happens to be between the thighs.

The legs and breech of the child being brought down, and the body properly turned with the fore parts to the mother's back, let the accoucheur endeavour to bring it along; but, if it is detained by the size of the belly, distended with air or water, (a case that frequently happens when the child has been dead for several days,) let the belly be opened, by forcing into it the points of his scissars; or, he may tear it open with the sharp crotchet.

The body of the child being delivered, the arms brought down, and every method hitherto directed unsuccessfully used for the extraction of the head, which is detained by being naturally too large, over ossified, or dropical, or from the narrowness and distortion of the pelvis; if the belly was not opened, and the child is found to be alive by the motion of the heart, or pulsation of the arteries in the funis, the forceps ought to be tried; but, if he finds it impracticable to deliver the head, so as to save the life of the child, he must, according to some, force the points of the scissars through the lower part of the occipital bone, or through the foramen magnum; then dilate the blades, so as to enlarge the opening, and introduce a blunt or sharp hook. This operation rarely succeeds when the head is over-ossified; but may answer the purpose when the bones are soft and yielding; or in the case of an hydrocephalus: because, in the first, the aperture may sometimes be enlarged, and in the other the water will be evacuated so as to diminish the bulk of the head, which will, of consequence, come along with more ease.

If, notwithstanding these endeavours, the head cannot be extracted, let the operator introduce his hand along the head, and his fingers through the os uteri; then slide up one of the curved crotchets along the ear, betwixt his hand and the child's head, upon the upper part of which it must be fixed: this being done, let him withdraw his hand, take hold of the instrument with one hand, turning the curve of it over the forehead, and with the other grasp the neck and shoulders, then pull along. The crotchet being thus fixed on the upper part, where the bones are thin and yielding, makes a large opening, through which the contents of the skull are emptied, the head collapsing is with more certainty extracted, and the instrument hath a firm hold to the last, at the forehead, os petrosum, and basis of the skull.

The excellency of *Mesnard's* contrivance is more conspicuous here than when the head presents; because the curvature of the crotchet allows the point to be fixed on the upper part of the skull, which is to be tore open; and in pulling, the contents are evacuated, and the head is lessened: by these means, the principal obstruction is removed. See Plate CXIII. fig. 8.

a, Represents a pair of curved crotchets locked together in the same manner as the forceps. The dotted lines along the inside of one of the blades represent a sheath contrived to guard the point till it is intro-

duced high enough; the ligature at the handles marked with the two dotted lines is then to be untied, the sheath withdrawn, and the point, being uncovered, is fixed as in Plate CXIII. fig. 5.

b, Gives a view of the back part of one of the crotchets, which is 12 inches long.

c, A front view of the point, to shew its proportional length and breadth.

d, The scissars for perforating the cranium in very narrow and distorted pelvis's. They ought to be made very strong, and at least nine inches in length, with stops or reils in the middle of the blades, by which a large dilatation is more easily made.

If one crotchet be found insufficient, let him introduce the other in the same manner, along the opposite side, lock and join them together, and pull along, moving and turning the head, so as to humour the shape of the pelvis. This method seldom fails to accomplish his aim, though sometimes very great force is required; in which case, he must pull with leisure and caution.

But if all these expedients should fail, by reason of the extraordinary ossification or size of the head, or the narrowness and distortion of the pelvis, after having used the crotchets without success, he must separate the body from the head with a bistoury or pair of scissars; then pushing up the head into the uterus, turn the face to the fundus, and the vertex down to the os internum and brim of the pelvis: let him direct an assistant to press upon the woman's belly with both hands, in order to keep the uterus and head firm in that position; then open the skull with the scissars, destroy the structure of the brain, and extract with the crotchets.

The head is sometimes left in the uterus by those practitioners, who not knowing how to turn the fore-parts and face of the child towards the back part of the uterus, or how to bring it along, although it presented in that position, pull at random with all their strength; so that the neck is stretched and separated, and the head left behind. This may also happen to an expert accoucheur, when the child hath been dead for many days, and the body is much mortified, even though he hath used all the necessary precautions.

In such a case, provided the head is not very large, nor the pelvis narrow, and the forehead is towards the sacrum, let him slide up his hand along the back-part of the pelvis, and introducing two fingers into the mouth, with the thumb below the chin, try to pull the forehead into the hollow of the sacrum: if it sticks at the jetting-in of that bone, he must endeavour to move it, first to one side, and then to the other. If the head is small, it will come along; if any fragment of the neck remains, or any part of the loose skin, he may lay hold on it, and assist delivery, by pulling at it with his other hand; if the head is low down, it may be extracted with the forceps.

Should all these methods fail, let him push up his hand along the side of the head, until it shall have passed the os internum; with the other hand, let him introduce one of the curved crotchets, and fix it upon the upper part of the head; then withdrawing the hand which was introduced, take hold on the instrument, and sliding the fingers of the other hand into the mouth, he must pull

down with both, as above directed. If the head is not over-ossified, the crotchet will tear open the skull; and the bulk being of consequence diminished, the whole may be brought along, even in a narrow pelvis: but if it cannot be moved, even by this expedient, he must introduce the other crotchet along the other side of the head, and fixing it upon the skull, lock them together; then in pulling, turn the fore-head down into the hollow of the sacrum, and extract with an half round turn upwards, as when delivering with the forceps.

If the forehead is towards the os pubis, and cannot be brought into the right position, let him with his hand push up the head into the uterus, turn the forehead from the anterior to the side or back part of it, and try to extract as before. If the child hath been dead some time, and is much mortified, he must pull cautiously at the under jaw, because, should that give way, he will have no other hold for pulling, or keeping the head steady when he attempts to extract with one crotchet.

When the head is so large, or the pelvis so narrow, that none of these methods will succeed, let him push up, and turning the upper parts downwards, direct an assistant to press the patient's belly with both hands, moving them from side to side, and squeezing in such a direction as will force the head towards the os internum, and retain it firmly in that position; then it must be opened and extracted.

Although, by these means, you may succeed in a few cases of this kind, yet as great difficulties may occur from inflammations of the pudenda, contraction of the uterus, slipperiness or largeness of the head, and the narrowness of the pelvis, it will not be improper to inform the reader of other methods that appear to be useful. Let the hand be introduced into the vagina, and if it cannot be admitted within the uterus, the fingers being insinuated, may move the head so as to raise the face and chin to the fundus, the vertex being turned to the os internum, and the forehead towards the side of the sacrum. This being effected, let the operator slide up along one ear a blade of the long forceps, which are curved to the side; then change hands, and send up the other blade along the opposite ear: when they are locked, and the handles secured by a fillet, he must pull the head as low as it will come; then putting them into the hands of an assistant, who will keep them in that position, let him make a large opening with the scissars, squeeze the head with great force, and extract slowly and by degrees.

Having turned down the vertex, as above directed, let *Leverot's* tire tête, with the three slides joined together, be introduced along the accoucheur's hand to the upper part of the head; then let the slides or blades be opened with the other hand, so as to inclose the head, moving them circularly and lengthwise in a light and easy manner, that they may pass over the inequalities of the scalp, and avoid the resistance of the head and uterus: when they are exactly placed at equal distances from one another, let him join the handles, withdraw his hand, and tying them together with a fillet, pull down, open, and extract, as above directed; and let it be remembered, that the farther the hand can be introduced into the uterus, the more easily will both instruments be managed.

When

When the pelvis is large, or the head small, (in which cases this misfortune seldom happens,) without doubt we might succeed with *Mauriceau's* broad fillet or sling, provided it could be properly applied.

When the head is small, or the pelvis large, dilating the foramen magnum with the scissars, and introducing the blunt hook, may be of use either to pull the head along, or keep it down until we can fix the forceps, curve crotchet, or *Leveret's* tire-tête.

Of TWINS.

TWINS are supposed to be the effect of a double conception in one coition, when two or more ova are impregnated with as many animalcula; which descending from the ovarium, through the Fallopian tube, into the fundus uteri, as they increase, come in contact with that part, and with one another, and are so pressed as to form one globular figure, and stretch the womb into the same form which it assumes when distended by one ovum only; and that during the whole term of uterine gestation, it is impossible to distinguish twins, either by the figure and magnitude of the uterus, or by the motion of the different foetuses; for one child, when it is large, and surrounded with a great quantity of waters, will sometimes produce as large a prominence (or even larger) in the woman's belly, than is commonly observed when she is big with twins. One child will also, by moving its legs, arms, and other parts of its body, against different parts of the uterus, at the same instant, or by intervals, yield the same sensation to the mother, as may be observed in two or more children; for part of the motion in twins is employed on each other, as well as upon the uterus.

There is therefore no certain method of distinguishing in these cases, until the first child is delivered, and the accoucheur has examined if the placenta is coming along. If this comes of itself, and after its extraction the mouth of the womb be felt contracted, and the operator is unwilling to give unnecessary pain by introducing his hand into the uterus; let him lay his hand upon the woman's abdomen, and if nothing is left in the womb, he will generally feel it just above the os pubis, contracted into a firm round ball of the size of a child's head, or less: whereas, if there is another child left, the size will be found much larger. If the placenta does not come down before the second child, which is frequently the case, upon examining, he will commonly feel the membranes with the waters pushed down through the os uteri; or if they are broke, the head or some part of the body will be felt. If, therefore, the woman has strong pains, and is in no danger from floodings or weakness, provided the head presents fair, and seems to come along, she will be delivered of this also in the natural way.

If the membranes are not broke, if the head does not immediately follow, or if the child presents wrong, he ought to turn and bring it immediately by the feet; in order to save the patient the fatigue of a second labour, that may prove tedious, and even dangerous, by enfeebling her too much. Besides, as the parts are fully opened by the first delivery, he can introduce his hand with ease; and as the membranes are, for the most part, whole, the wa-

ters may be kept up, and the foetus easily turned; but, if the pelvis is narrow, the woman strong, and the head presents, he ought to leave it to the efforts of nature.

If the child presents wrong, and, in turning that, he feels another, he must beware of breaking the membranes of one, while he is at work upon the other: but, should they chance to be broke, and the legs of both entangled together, (though this is seldom the case, because they are commonly divided by two sets of membranes,) let the operator, when he has got hold on two legs, run up his fingers to the breech, and feel if they belong to the same body; and one child being delivered, let the other be turned and brought out in the same manner. If there are more than two, the same method must take place, in extracting one after another.

In case of twins, the placenta of the first seldom comes along, until the second child is delivered; but, as this does not always happen, he ought, as formerly directed, to certify himself that there is nothing left in the uterus, when the cake comes of itself. Both children being delivered, let him extract both placentas, if they come not of themselves; and if they form distinct cakes, separate first one, then the other; but if they are joined together, forming but one mass, they may be delivered at once.

When there are three or four children, (a case that rarely happens,) the placentas are sometimes distinct, and sometimes all together form but one round cake; but, when this is macerated in water for some days, they, with their several membranes, may be easily separated from one another; for they only adhere in consequence of their long pressure in the uterus, and seldom have any communication of vessels.

Twins for the most part lie diagonally in the uterus, one below the other; so that they seldom obstruct one another at the os interium. See Plate CXL. fig. 5.

Of MONSTERS.

Two children joined together by their bellies, (which is the most common case of monstrous births,) or by the sides, or when the belly of the one adheres to the back of the other, having commonly but one funis, are comprehended in this class, and supposed to be the effect of two animalcula impregnating the same ovum, in which they grow together, and are nourished by one navel-string, originally belonging to the secundines; because, the vessels pertaining to the coats of the vein and arteries, do not anastomose with the vessels belonging to the foetus.

In such a case, where the children were small, the adhesion hath been known to stretch in pulling at the feet of one, so as to be delivered; and the other hath been afterwards brought along, in the same manner, without the necessity of a separation.

When the accoucheur is called to a case of this kind, if the children are large, and the woman come to her full time, let him first attempt to deliver them by that method: but if, after the legs and part of the body of the first are brought down, the rest will not follow, let him slide up his hand, and with his fingers examine the adhesion; then introducing the scissars between his hand and the body of the foetus, endeavour to separate them by snipping.

snipping through the juncture. Should this attempt fail, he must diminish the bulk in the best manner he can think of, and bring the body of the fist, in different pieces, by pulling or cutting them asunder, as he extracts with the help of the crotchet.

No certain rules can be laid down in these cases, which seldom happen; and therefore a great deal must be left to the judgment and sagacity of the operator, who must regulate his conduct according to the circumstances of the case, and according to the directions given for delivering, when the pelvis is narrow and the children extraordinary large.

Of the CÆSARIAN OPERATION.

WHEN a woman cannot be delivered by any of the methods hitherto described and recommended in laborious and preternatural labours, on account of the narrowness or distortion of the pelvis, into which it is sometimes impossible to introduce the hand; or from large excrescences and glandular swellings, that fill up the vagina, and cannot be removed; or from large cicatrices and adhesions in that part, and at the os uteri, which cannot be separated; in such emergencies, if the woman is strong, and of a good habit of body, the Cæsarion operation is certainly advisable, and ought to be performed; because the mother and child have no other chance to be saved, and it is better to have recourse to an operation which hath sometimes succeeded, than leave them both to inevitable death. Nevertheless, if the woman is weak, exhausted with fruitless labour, violent floodings, or any other evacuation, which renders her recovery doubtful, even if she were delivered in the natural way: in these circumstances it would be rashness and presumption to attempt an operation of this kind, which ought to be delayed until the woman expires, and then immediately performed, with a view to save the child.

The operation hath been performed both in this and the last century, and sometimes with such success, that the mother has recovered, and the child survived. The previous steps to be taken, are to strengthen the patient, if weak, with nourishing broths and cordials; to evacuate the indurated fæces with repeated glysters; and, if the bladder is distended with urine, to draw it off with a catheter. These precautions being taken, she must be laid on her back, on a couch or bed, her side on which the incision is to be made being raised up by pillows placed below the opposite side: the operation may be performed on either side, though the left is commonly preferred to the right; because, in this last, the liver extends lower. The apparatus consists of a bistory, probe-scissors, large needles threaded, sponges, warm water, pledgets, a large tent or dosil, compresses, and a bandage for the belly.

If the weather is cold, the patient must be kept warm, and no part of the belly uncovered, except that on which the incision is to be made: if the operator be a young practitioner, the place may be marked by drawing a line along the middle space between the navel and the os ilium, about six or seven inches in length, slanting forwards towards the left groin, and beginning as high as the navel.

According to this direction, let him hold the skin of

the abdomen tense between the finger and thumb of one hand, and, with the bistory in the other, make a longitudinal incision through the cutis, to the membrana adiposa, which, with the muscles, must be slowly dissected, and separated, until he reaches the peritonæum, which must be divided very cautiously, for fear of wounding the intestines that frequently start up at the sides, especially in the membranes are broke, the waters discharged, and the uterus contracted.

The peritonæum being laid bare, it may either be pinched up by the fingers, or slowly dissected with the bistory, until an opening is made sufficient to admit the fore-finger, which must be introduced as a director for the bistory or scissors in making an effectual dilatation. If the intestines push out, let them be pressed downwards, so as that the uterus may come in contact with the opening. If the womb is still distended with the waters, and at some distance from the child, the operator may make upon it a longitudinal incision at once; but if it is contracted close round the body of the fœtus, he must pinch it up, and dilate in the same cautious manner practised upon the peritonæum, taking care to avoid wounding the Fallopian tubes, ligaments, and bladder; then introducing his hand, he may take out the child and secundines. If the woman is strong, the uterus immediately contracts, so as that the opening, which at first extended to about six or seven inches, is reduced to two, or less; and in consequence of this contraction, the vessels being shrunk up, a great effusion of blood is prevented.

The coagulated blood being removed, and what is still fluid sponged up, the incision in the abdomen must be stitched with the interrupted suture, and sufficient room left between the last stitch and the lower end of the opening, for the discharge of the moisture and extravasated fluid. The wound may be dressed with dry pledgets or dosils dipped in some liquid balsam warmed, covered with compresses moistened with wine, and a bandage to keep on the dressings and sustain the belly. Some authors observe, that the cutis and muscles only should be taken up in the suture, lest bad symptoms should arise from stitching the peritonæum.

The woman must be kept in bed, as quiet as possible, and every thing administered to promote the lochia, perspiration, and sleep: which will prevent a fever and other dangerous symptoms. If she hath lost a great quantity of blood from the wounds in the uterus and abdomen, so as to be in danger from inanition, broths, caudles and wine, ought to be given in small quantities, and frequently repeated; and the Peruvian bark administered in powder, decoction, or extract, may be of great service in this case.

Of the management of women from the time of their delivery to the end of the month, with the several diseases to which they are subject during that period.

Of the EXTERNAL APPLICATION.

THE woman being delivered of the child and placenta, let a soft linen cloth, warmed, be applied to the external parts; and if she complains much of a smarting soreness, some pomatum may be spread upon it. The linen that

that was laid below her, to sponge up the discharges, must be removed, and replaced with others that are clean, dry, and warm. Let her lie on her back, with her legs extended close to each other; or upon her side, if she thinks she can lie easier in that position, until she recovers from the fatigue: if she is spent and exhausted, let her take a little warm wine or caudle, or, according to the common custom, some nutmeg and sugar grated together in a spoon: the principal design of administering this powder, which among the good women is seldom neglected, is to supply the want of some cordial draught, when the patient is too weak to be raised, or supposed to be in danger of reachings from her stomach's being overloaded. When she hath in some measure recovered her strength and spirits, let the cloths be removed from the parts, and others applied in their room; and, if there is a large discharge from the uterus, let the wet linen below her be also shifted, that she may not run the risque of catching cold.

When the patient is either weak or faintish, she ought not to be taken out of bed, or even raised up to have her head and body shifted, until she is a little recruited; otherwise she will be in danger of repeated faintings, attended with convulsions, which sometimes end in death. To prevent these bad consequences, her skirt and petticoats ought to be loosened and pulled down over the legs, and replaced by another well warmed, with a broad head-band to be slipped in below, and brought up over her thighs and hips: a warm double cloth must be laid on the belly, which is to be surrounded by the head-band of the skirt pinned moderately tight over the cloth, in order to compress the viscera and the relaxed parietes of the abdomen, more or less, as the woman can easily bear it; by which means the uterus is kept firm in the lower part of the abdomen, and prevented from rolling from side to side when the patient is turned: but the principal end of this compression, is to hinder too great a quantity of blood from rushing into the relaxed vessels of the abdominal contents; especially when the uterus is emptied all of a sudden, by a quick delivery. The pressure being thus suddenly removed, the head is all at once robbed of its proportion of blood, and the immediate revulsion precipitates the patient into dangerous lypothymia.

For this reason the belly ought to be firmly compressed by the hands of an assistant, until the bandage is applied; or, in lieu of it, a long towel, sheet, or roller, to make a suitable compression: but, for this purpose, different methods are used in different countries, or according to the different circumstances of the patients. The head-cloaths and shift ought also to be changed, because with sweating in time of labour they are rendered wet and disagreeable. Several other applications are necessary, when the external or internal parts are rent or inflamed, misfortunes that sometimes happen in laborious and preternatural cases. See *MEDICINE*, p. 165, 166.

Of Air, Diet, Sleeping and Watching, Motion and Rest, Retention and Excretion, and the Passions of the Mind.

ALTHOUGH we cannot remove the patient immediately after delivery into another climate, we can qualify the

VOL. III. N^o. 79.

2

air, so as to keep it in a moderate and salutary temper, by rendering it warm or cold, moist or dry, according to the circumstances of the occasion. With regard to diet, women in time of labour, and even till the ninth day after delivery, ought to eat little solid food, and none at all during the first five or seven: let them drink plentifully of warm diluting fluids, such as barley-water, gruel, chicken-water, and tea; caudles are also commonly used, composed of water gruel boiled up with mace and cinnamon, to which, when strained, is added a third or fourth part of white wine, or less, if the patient drinks plentifully, sweetened with sugar to their taste: this composition is termed white caudle; whereas, if ale is used instead of wine, it goes under the name of brown caudle. In some countries, eggs are added to both kinds; but, in that case, the woman is not permitted to eat meat or broths till after the fifth or seventh day: in this country, however, as eggs are no part of the ingredients, the patient is indulged with weak broth sooner, and sometimes allowed to eat a little boiled chicken. But all these different preparations are to be prescribed weaker or stronger, with regard to the spices, wine, or ale, according to the different constitutions and situations of different patients: for example, if she is low and weak, in consequence of an extraordinary discharge of any kind, either before or after delivery, or if the weather is cold, the caudles and broths may be made the stronger; but if she is of a full habit of body, and has the least tendency to a fever, or if the season is excessively hot, these drinks ought to be of a very weak consistence, or the patient restricted to gruel, tea, barley and chicken water; and these varied according to the emergency of the case.

Her food must be light and easy of digestion, such as panada, biscuit, and sago; about the fifth or seventh day she may eat a little boiled chicken, or the lightest kind of young meat: but, these last may be given sooner or later, according to the circumstances of the case, and the appetite of the patient. In the regimen as to eating and drinking, we should rather err on the abstemious side, than indulge the woman with meat and strong fermented liquors, even if these last should be most agreeable to her palate: for we find by experience, that they are apt to increase or bring on fevers, and that the most nourishing and salutary diet is that which we have above prescribed. Every thing that is difficult of digestion, or quickens the circulating fluids, must of necessity promote a fever; by which, the necessary discharges are obstructed, and the patient's life endangered.

As to the article of sleeping and watching, the patient must be kept as free from noise as possible, by covering the floors and stairs with carpets and cloths, oiling the hinges of the doors, silencing the bells, tying up the knockers, and in noisy streets throwing the pavement with straw; if, notwithstanding these precautions, she is disturbed, her ears must be stuffed with cotton, and opiates administered to procure sleep; because watching makes her restless, prevents perspiration, and promotes a fever.

Motion and rest are another part of the nonnaturals to which we ought to pay particular regard. By tossing about, getting out of bed, or sitting up too long, the perspiration is discouraged and interrupted; and in this last

3 P

†

attitude

attitude the uterus, not yet fully contracted, hangs down, stretching the ligaments, occasioning pain, cold shiverings, and a fever: for the prevention of these bad symptoms, the patient must be kept quiet in bed till after the fourth or fifth day, and then be gently lifted up in the bed-cloaths, in a lying posture, until the bed can be adjusted, into which she must be immediately re-conveyed, there to continue for the most part, till the ninth day, after which period women are not so subject to fevers, as immediately after delivery. Some there are, who, from the nature of their constitutions, or other accidents, recover more slowly; and such are to be treated with the same caution after, as before, the ninth day, as the case seems to indicate: others get up, walk about, and recover, in a much shorter time; but these may some time or other pay dearly for their foolhardiness, by encouraging dangerous fevers: so that we ought rather to err on the safe side, than run any risque whatsoever.

What next comes under consideration, is the circumstance of retention and excretion. We have formerly observed, that in time of labour, before the head of the child is locked into the pelvis, if the woman has not had easy passage in her belly that same day, the rectum and colon ought to be emptied by a glyster, which will assist the labour, prevent the disagreeable excretion of the fœces before the child's head, and enable the patient to remain two or three days after, without the necessity of going to stool. However, should this precaution be neglected, and the patient very covetous after delivery, we must beware of throwing up stimulating glysters, or administering strong cathartics, lest they should bring on too many loose stools, which, if they cannot be stopped, sometimes produce fatal consequences, by obstructing the perspiration and lochia, and exhausting the woman, so as that she will die all of a sudden; a catastrophe which hath frequently happened from this practice. Wherefore, if it be necessary to empty the intestines, we ought to prescribe nothing but emollient glysters, or some very gentle opener, such as manna, or *Elest. Lenitivum*. But no excretion is of more consequence to the patient's recovery, than a free perspiration; which is so absolutely necessary, that unless she has a moisture continually on the surface of her body, for some days after the birth, she seldom recovers to advantage: her health, therefore, in a great measure depends upon her enjoying undisturbed repose, and a constant breathing sweat, which prevents a fever, by carrying off the tension, and assists the equal discharge of the lochia: and when these are obstructed, and a fever ensues with pain and restlessness, nothing relieves the patient so effectually as rest and profuse sweating, procured by opiates and sudorifics at the beginning of the complaints; yet these last must be more cautiously prescribed in excessive hot than in cool weather.

The last of the nonnaturals to be considered are the passions of the mind, which also require particular attention. The patient's imagination must not be disturbed by the news of any extraordinary accident which may have happened to her family or friends: for such information hath been known to carry off the labour-pains entirely, after they were begun, and the woman has sunk under her dejection of spirits: and even after delivery, these un-

seasonable communications have produced such anxiety as obstructed all the necessary excretions, and brought on a violent fever and convulsions, that ended in death.

Of violent FLOODINGS.

ALL women, when the placenta separates, and after it is delivered, lose more or less red blood, from the quantity of half a pound, to that of one pound, or even two; but should it exceed this proportion, and continue to flow without diminution, the patient is in great danger of her life: this hazardous hæmorrhage is known by the violence of the discharge, wetting fresh cloths as fast as they can be applied; from the pulse becoming low and weak, and the countenance turning pale; then the extremities grow cold, the sinks into faintings, and, if the discharge is not speedily stopped, or diminished, is seized with convulsions, which often terminate in death.

This dangerous efflux is occasioned by every thing that hinders the emptied uterus from contracting, such as great weakness and lassitude, in consequence of repeated floodings before delivery; the sudden evacuation of the uterus; sometimes, though seldom, it proceeds from part of the placenta's being left in the womb; it may happen when there is another child, or more, still undelivered; when the womb is kept distended with a large quantity of coagulated blood; or when it is inverted, by pulling too forcibly at the placenta.

In this case, as there is no time to be lost, and internal medicines cannot act so suddenly as to answer the purpose, we must have immediate recourse to external application. If the disorder be owing to weakness, by which the uterus is disabled from contracting itself, so that the mouths of the vessels are left open; or, though contracted a little, yet not enough to restrain the hæmorrhage of the thin blood; or if, in separating the placenta, the accoucheur has scratched or tore the inner surface or membrane of the womb; in these cases, such things must be used as will assist the contractile power of the uterus, and hinder the blood from flowing so fast into it and the neighbouring vessels; for this purpose, cloths dipped in a cold astringent fluid, such as oxyacret, or red tart wine, may be applied to the back and belly. Some prescribe venæsection in the arm, to the amount of five or six ounces, with a view of making revulsion: if the pulse is strong, this may be proper; otherwise, it will do more harm than good. Others order ligatures, for compressing the returning veins at the hams, arms, and neck, to retain as much blood as possible in the extremities and head. Besides these applications, the vagina may be filled with tow or linen rags, dipped in the above-mentioned liquors, in which a little alum, or sacchar saturni hath been dissolved: nay, some practitioners inject proof-spirits warmed, or, soaking them up in a rag or sponge, introduce and squeeze them into the uterus, in order to constrict the vessels.

If the flooding proceeds from another child, the retention of the placenta, or coagulated blood, these ought immediately to be extracted; and if there is an inversion of the uterus, it must be speedily reduced. Should the hæmorrhage, by these methods, abate a little, but still continue to flow, though not in such a quantity as to bring on sudden death, some red wine and jelly ought to be

be prescribed for the patient, who should take it frequently, and a little at a time; but above all things, chicken or mutton broths, administered in the same manner, for fear of overloading the weakened stomach, and occasioning reachings: these repeated in small quantities, will gradually fill the exhausted vessels, and keep up the circulation. If the pulse continues strong, it will be proper to order repeated draughts of barley-water, acidulated with elixir vitriol: but if the circulation be weak and languid, extract of the bark, dissolved in *aq. cinnamomi tenuis*, and given in small draughts, or exhibited in any other form, will be serviceable; at the same time, lulling the patient to rest with opiates. These, indeed, when the first violence of the flood is abated, if properly and cautiously used, are generally more effectual than any other medicine.

Of the AFTER-PAINS.

AFTER-PAINS commonly happen when the fibrous part of the blood is retained in the uterus or vagina, and formed into large clots, which are detained by the sudden contraction of the os internum and externum, after the placenta is delivered: or, if these should be extracted, others will sometimes be formed, though not so large as the first, because the cavity of the womb is continually diminishing after the birth. The uterus, in contracting, presses down these coagulums to the os internum; which being again gradually stretched, produces a degree of labour pains, owing to the irritation of its nerves: in consequence of this uneasiness, the woman squeezes the womb as in real labour; the force being increased, the clots are pushed along, and when they are delivered, the grows easy. The larger the quantity is of the coagulated blood, the severer are the pains, and the longer they continue.

Women in the first child seldom have after-pains; because, after delivery, the womb is supposed to contract, and push off the clots with greater force in the first than in the following labours: after-pains may also proceed from obstructions in the vessels, and irritations at the os internum. In order to prevent or remove these pains, as soon as the placenta is separated and delivered, the hand being introduced into the uterus, may clear it of all the coagula. When the womb is felt through the parietes of the abdomen larger than usual, it may be taken for granted, that there is either another child, or a large quantity of this clotted blood; and, whichsoever it may be, there is a necessity for its being extracted. If the placenta comes away of itself, and the after-pains are violent, they may be alleviated and carried off by an opiate: for, by sleeping and sweating plentifully, the irritation is removed, the evacuations are increased, the os uteri is insensibly relaxed, and the coagula slide easily along. When the discharge of the lochia is small, the after-pains, if moderate, ought not to be restrained; because the squeezing which they occasion, promotes the other evacuation, which is necessary for the recovery of the patient. After-pains may also proceed from an obstruction in some of the vessels, occasioning a small inflammation of the os internum and ligaments; and the squeezing thereby occasioned, may not only help to propel the obstructing fluid, but al-

so (if not too violent) contribute to the natural discharges.

Of the LOCHIA.

We have already observed, that the delivery of the child and placenta is followed by an efflux of more or less blood, discharged from the uterus, which, by the immediate evacuation of the large vessels, is allowed to contract itself the more freely, without the danger of an inflammation, which would probably happen in the contraction, if the great vessels were not emptied at the same time: but, as the fluids in the smaller vessels cannot be so soon evacuated, or returned into the vena cava, it is necessary, that, after the great discharge is abated, a slow and gradual evacuation should continue, until the womb shall be contracted to near the same size which it had before pregnancy; and to this it attains about the eighteenth or twentieth day after delivery, though the period is different in different women.

When the large vessels are emptied immediately after delivery, the discharge frequently ceases for several hours, until the fluids in the smaller vessels are propelled into the larger, and then begins to flow again, of a paler colour.

The red colour of the lochia commonly continues till the fifth day, though it is always turning more and more ferrous from the beginning; but, about the fifth day, it flows off a clear, or sometimes (though seldom) of a greenish tint; for, the mouths of the vessels growing gradually narrower, by the contraction of the uterus, at last allow the ferrous part only to pass: as for the greenish hue, it is supposed to proceed from a dissolution of the cellular or cribriform membrane or mucus, that surrounded the surface of the placenta and chorion; part of which, being left in the uterus, becomes livid, decays, and, dissolving, mixes with and tinctures the discharge as it passes along.

Though the lochia, as we have already observed, commonly continue to the eighteenth or twentieth day, they are every day diminishing in quantity, and soonest cease in those women who suckle their children, or have had an extraordinary discharge at first; but the colour, quantity, and duration, differ in different women: in some patients, the red colour disappears on the first, or second day; and in others, though rarely, it continues more or less to the end of the month: the evacuation in some is very small, in others excessive: in one woman it ceases very soon, in another flows during the whole month: yet, all of these patients shall do well.

Some allege, that this discharge from the uterus is the same with that from a wound of a large surface: but it is more reasonable to suppose, that the change of colour and diminution of quantity proceed from the slow contraction of the vessels; because, previous to pus, there must have been lacerations or imposthumes, and in women who have suddenly died after delivery no wound or excoriation hath appeared upon the inner surface of the womb, which is sometimes found altogether smooth, and at other times rough and unequal on that part to which the placenta adhered. The space that is occupied before delivery, from being six inches in diameter, or eighteen inches in circumference, will, soon after the birth, be contracted to one third or fourth of these dimensions.

Of the Milk Fever.

ABOUT the fourth day, the breasts generally begin to grow turgid and painful. We have formerly observed, that, during the time of uterine gestation, the breasts in most women gradually increase till the delivery, growing softer as they are enlarged by the vessels being more and more filled with fluids; and by this gradual distention they are prepared for secreting the milk from the blood, after delivery. During the two or three first days after parturition, especially when the woman has undergone a large discharge, the breasts have been sometimes observed to subside and grow flaccid; and about the third or fourth day, when the lochia begin to decrease, the breasts swell again to their former size, and stretch more and more, until the milk, being secreted, is either sucked by the child, or frequently of itself runs out at the nipples.

Most of the complaints incident to women after delivery, proceed either from the obstruction of the lochia in the uterus, or of the milk in the breasts, occasioned by any thing that will produce a fever; such as catching cold, long and severe labour, eating food that is hard of digestion, and drinking fluids that quicken the circulation of the blood in the large vessels; by which means the smaller, with all the secretory and excretory ducts, are obstructed.

The discharge of the lochia being so different in women of different constitutions, and besides in some measure depending upon the method of management, and the way of life peculiar to the patient, we are not to judge of her situation from the colour, quantity, and duration of them, but from the other symptoms that attend the discharge; and if the woman seems hearty, and in a fair way of recovery, nothing ought to be done with a view to augment or diminish the evacuation. If the discharge be greater than she can bear, it will be attended with all the symptoms of inanition; but as the lochia seldom flow so violently as to destroy the patient of a sudden, she may be supported by a proper nourishing diet, assisted with cordial and restorative medicines. Let her, for example, use broths, jellies, and asses milk; if the pulse is languid and sunk, she may take repeated doses of the *confect. cardiac.* with mixtures composed of the cordial waters and volatile spirits: subastringents and opiates frequently administered, with the *cort. Peruvian.* in different forms, and austere wines, are of great service. On the other hand, when the discharge is too small, or hath ceased altogether, the symptoms are more dangerous, and require the contrary method of cure: for now the business is to remove a too great plenitude of the vessels in and about the uterus, occasioning tension, pain, and labour, in the circulating fluids; from whence proceed great heat in the part, restlessness, fever, a full, hard, quick pulse, pains in the head and back, nausea, and difficulty in breathing. These complaints, if not at first prevented, or removed by rest and plentiful sweating, must be treated with venesection and the antiphlogistic method.

When the obstruction is recent, let the patient lie quiet, and encourage a plentiful diaphoresis, by drinking

frequently of warm, weak, diluting fluids, such as water-gruel, barley-water, tea, or weak chicken-broth.

Should these methods be used without success, and the patient, far from being relieved by rest, plentiful sweating, or a sufficient discharge of the obstructed lochia, labour under an hot dry skin, anxiety, and a quick, hard, and full pulse, the warm diaphoretics must be laid aside; because, if they fail of having the desired effect, they must necessarily increase the fever and obstruction, and recourse be had to bleeding at the arm or ankle to more or less quantity, according to the degree of fever and obstruction; and this evacuation must be repeated as there is occasion. When the obstruction is not total, it is supposed more proper to bleed at the ankle than at the arm; and at this last, when the discharge is altogether stopped. Her ordinary drink ought to be impregnated with nitre.

If she is colic, emollient and gently opening glysters may be occasionally injected; and her breasts must be formed and sucked, either by the mouth or pipe-glasses. If, by these means, the fever is abated, and the necessary discharges return, the patient commonly recovers; but, if the complaints continue, the antiphlogistic method must still be pursued. If, notwithstanding these efforts, the fever is not diminished or removed by a plentiful discharge of the lochia from the uterus, the milk from the breasts, or by a critical evacuation by sweat, urine, or stool, and the woman is every now and then attacked with cold shiverings; an abscess or abscesses will probably be formed in the uterus or neighbouring parts, or in the breasts; and sometimes, the matter will be translocated to other situations, and the seat of it foretold from the part's being affected with violent pains: these abscesses are more or less dangerous, according to the place in which they happen, the largeness of the suppurations, and the good or bad constitution of the patient.

If when the pains in the epigastric region are violent, and the fever increased to a very high degree, the patient should all of a sudden enjoy a cessation from pain, without any previous discharge or critical emission, the physician may pronounce that a mortification is begun; especially if, at the same time, the pulse becomes low, quick, wavering, and intermitting: if the woman's countenance, from being florid, turns dusky and pale, while she herself, and all the attendants, conceive her much mended; in that case, she will grow delirious, and die in a very short time.

What we have said on this subject, regards that fever which proceeds from the obstructed lochia, and in which the breasts may likewise be affected: but the milk fever is that in which the breasts are originally concerned, and which may happen though the lochia continue to flow in sufficient quantity; nevertheless, they mutually promote each other, and both are to be treated in the manner already explained; namely, by opiates, diluents, and diaphoretics, in the beginning; and, these prescriptions failing, the obstructions must be resolved by the antiphlogistic method described above. The milk-fever alone, when the uterus is not concerned, is not so dangerous, and much more easily relieved. Women of an healthy constitution, who suckle their own children, have good nipples,

ples, and whose milk comes freely, are seldom or never subject to this disorder, which is more incident to those who do not give suck, and neglect to prevent the secretion in time; or, when the milk is secreted, take no measures for emptying their breasts. This fever likewise happens to women who try too soon to suckle, and continue their efforts too long at one time; by which means, the nipples, and consequently the breasts, are often inflamed, swelled, and obstructed.

In order to prevent too great a turgency in the vessels of the breasts, and the secretion of milk, in those women who do not chuse to suckle, it will be proper to make external application of those things which by their pressure and repercussive force will hinder the blood from flowing in too great quantity to this part, which is now more yielding than at any other time: for this purpose, let the breasts be covered with *emp. de minio, diapalma, or emp. simp.* spread upon linen, or cloths dipped in camphorated spirits, be frequently applied to these parts and the armpits; while the patient's diet and drink is of the lightest kind, and given in small quantities. Notwithstanding these precautions, a turgency commonly begins about the third day; but by rest, moderate sweating, and the use of these applications, the tension and pain will subside about the fifth or sixth day, especially if the milk runs out at the nipples: but if the woman catches cold, or is of a full habit of body, and not very abstemious, the tension and pain increasing, will bring on a cold shivering succeeded by a fever; which may obstruct the other excretions, as well as those of the breast.

In this case, the sudorifics above recommended must be prescribed; and if a plentiful sweat ensues, the patient will be relieved; at the same time the milk must be extracted from her breasts, by sucking with the mouth or glasses: should these methods fail, and the fever increase, she ought to be bled in the arm; and instead of the external applications hitherto used, emollient liniments and cataplasms must be substituted, in order to soften and relax. If, in spite of these endeavours, the fever proceeds for some days, the patient is frequently relieved by critical sweats, a large discharge from the uterus, milary eruptions, or loose stools mixed with milk, which is curdled in the intestines; but, should none of these eva-

cuations happen, and the inflammation continue with increasing violence, there is danger of an imposthume, which is to be brought to maturity, and managed like other inflammatory tumours; and no astringents ought to be applied, lest they should produce scirrhus swellings in the glands.

As the crisis of this fever, as well as of that last described, often consists in milary eruptions over the whole surface of the body, but particularly on the neck and breast, by which the fever is carried off, nothing ought to be given, which will either greatly increase or diminish the circulating force, but such only as will keep out the eruptions. But if, notwithstanding these eruptions, the fever, instead of abating, is augmented, it will be necessary to diminish its force, and prevent its increase, by those evacuations we have mentioned above. On the contrary, should the pulse sink, the eruptions begin to retreat inwardly, and the morbid matter be in danger of falling upon the viscera, we must endeavour to keep them out, by opiates and sudorific medicines; and here blisters may be applied with success.

Of the Evacuations necessary at the end of the Month after Delivery.

THOSE who have had a sufficient discharge of the lochia, plenty of milk, and suckle their own children, commonly recover with ease; and as the superfluous fluids of the body are drained off at the nipples, seldom require evacuations at the end of the month: but if there are any complaints from fullness, such as pains and stitches, after the twentieth day, some blood ought to be taken from the arm, and the belly gently opened by frequent glysters, or repeated doses of laxative medicines.

If the patient has tolerably recovered, the milk having been at first sucked or discharged from the nipples, and afterwards discussed, no evacuations are necessary before the third or fourth week; and sometimes not till after the first flowing of the menses, which commonly happens about the fifth week; if they do not appear within that time, gentle evacuations must be prescribed, to carry off the plethora, and bring down the catamenia.

M I L

MIGRATION, the passage or removal of a thing out of one place or state into another.

MILAN, the capital of the Milanese, or dutchy of Milan, in Italy: E. long. 9° 30', N. lat. 45° 25'.

MILBORN-PORT, a borough-town of Somersetshire, twenty-five miles south of Bath. It sends two members to parliament.

MILDEW, a disease happening to plants, caused by a dewy moisture supposed by some to be a species of blight.

MILE, *mille passus*, a measure of length or distance, containing eight furlongs, &c.

The English statute-mile is fourscore chains, or 1760 yards; that is 5280 feet.

of Denmark	5000
of Hungary	6000

MILFORD HAVEN, the most commodious harbour in Great Britain, situated in the south west part of Pembrokehire in Wales, at the north entrance of the Bristol channel.

MILIARY, in general, something resembling millet-seeds.

MILIARY FEVER. See **MEDICINE**, p. 73.

MILITANT, or **CHURCH MILITANT**, denotes the body of Christians while here on earth.

MILITARY, something belonging to the soldiery or militia.

MILITIA, in general, denotes the body of soldiers, or those who make profession of arms.

In a more restrained sense, militia denotes the trained bands of a town or country, who arm themselves, upon a short warning, for their own defence. So that, in this sense, militia is opposed to regular or stated troops.

For the direction and command of the militia, the king constitutes lords-lieutenants of each county.

MILIUM, in botany, a genus of the triandria digynia class. The corolla consists of two valves including one flower. There are five species, only one of which, viz. the effusum, or millet-grass, is a native of Britain.

MILK, a well known animal fluid, which nature prepares in the breasts of women, and the udders of other animals, for the nourishment of their young. Milk is a liquor prepared from the aliment chewed in the mouth, digested in the stomach, perfected by the force and juices of the intestines, and elaborated by means of the mesentery and its gland and juices, and the juices of the thoracic duct. It has undergone some actions of the veins, arteries, heart, lungs, and juices, and began to be assimilated; yet may still be had separate and discharged out of the body. And thus by their own milk, prepared from the proper matter of the chyle, all the known lactiferous animals are nourished, both male and female. For milk is always prepared from chyle as well in men as in women, in virgins and barren women, in mothers and nurses. Milk approaches nearer to an animal nature than chyle.

If milk be good, and suffered to rest in a clean vessel, it first appears uniformly white; then throws up a white, thick, unctuous cream to its surface, and remains somewhat bluish below. The milks of all the known animals have these properties alike. The human milk is very sweet and thin, the next is that of asses, then that of mares, then of goats, and lastly of cows: whence it is prescribed in this order to consumptive persons of weak viscera. The rennet prepared of the juices of such creatures as chew the cud being mixed with milk, coagulates it into an uniform mass, which may be cut with a knife, and it thus spontaneously separates into whey and curds; if long boiled over the fire, it loses its more fluid parts, and condenses into a butyrous and cheesy mass.

Milk is an efficacious remedy in disorders of the breast. But it is to be observed, that all milks are not of the same kind, and of the same efficacy for all purposes; since, according to the diversity of animals and their respective foods, they are possessed of different and peculiar qualities which are to be considered apart. First, then, asses milk, contains a great deal of sweet serum, but a very small quantity of earthy, caustic, and pinguious substance; for which reason it is not easily coagulated, and, consequently, but very unfit for butter and cheese. Its whey is astringent, laxative, moistening, and proper for correcting the acrimony of the humours. Goats milk does not contain so large a quantity of whey as that of asses, nor is it of so laxative and astringent a nature, but of a thicker consistence; and, as goats eat the leaves of trees which contain something of a resinous quality, their milk is very efficacious for the consolidation of suppurated parts. Cows-milk is more pinguious, contains a large quantity of earth, but less whey, for which reason it generally yields a great deal of butter and cheese. This species of milk is of a tempering, nutritive and consolidating virtue. Womens milk, for medicinal purposes, is preferable to all others; for it is the sweetest of them all, and its nutritive quality is sufficiently observable in infants. The virtues of milk are also different, according to the diversity of herbs and pasturage which animals eat. Hence milk in the spring is highly salutary, because at that time the vegetables abound with temperate juices; whereas milk in the winter is accounted less salutary, because the animals feed on hay and straw.

Dr. Cheyne recommends a milk and seed-diet, with water for drink, as the surest preservative against diseases, and cure of them.

MILK FEVER. See **MIDWIFERY**, p. 244.

MILL, a machine or engine for grinding corn, &c. of which there are several kinds, according to the various methods of applying the moving power; as water-mills, wind-mills, mills worked by horses, &c. See **MECHANICS**.

MILLENARIANS, or **CHILIASTS**, a name given to those, who, in the primitive ages, believed that the saints will one day reign on earth with Jesus Christ a thousand years.

MILLEPES. See **ONISCUS**.

MILLERIA, a genus of the syngenesia polygamia necessaria class. It has neither receptacle nor pappus; the calix consists of three valves; and the radius of the corolla is dimidiated. There are two species, both natives of America.

MILLET, in botany. See **MILIUM**.

MILLING of cloth. See **FULLING**.

MILLION, in arithmetick, the number of ten hundred thousand, or a thousand times a thousand. See **ARITHMETICK**.

MILLREE, a Portuguese gold coin, value 5 s 7½ d.

MILO, or **MELO**, one of the islands of the Archipelago, sixty miles north of Candia.

MILT, or **MELT**, is a denomination by which some call the rows of fishes.

MILTON,

MILTON, the name of several market-towns, as one twelve miles north east of Dorchester, and another twelve miles north east of Maidstone.

MILVUS, in ornithology. See **FALCO**.

MIME, in the ancient comedy, a person who acted any character by mere gestures, and hence denominated pantomime. See **PANTOMIME**.

MIMESIS, in rhetoric, the imitating the voice and gestures of another person.

MIMOSA, the SENSITIVE PLANT, in botany, a genus of the polygamia monœcia class. The calix of the hermaphrodite consists of five teeth, and the corolla of five segments; it has five or more stamina, one pistillum, and the fruit is a pod; the calix, corolla, and stamina of the male are the same with those of the female. There are 43 species, all natives of the Indies.—The mimosa is called the sensitive plant from its remarkable property of shrinking its leaves and branches upon being touched by the hand or any thing else. This motion it performs by means of three distinct articulations, viz. of a single leaf with its pedicle, of the pedicle to its branch, and of the branch to the trunk or main stem: the primary motion of all which is the closing of the two halves of the leaf on its rib: then the rib or pedicle itself closes; and if the motion wherewith the plant is moved be very strong, the very branches have the sensation propagated to them, and apply themselves to the main stem, as the simple leaves did before to their ribs, and these ribs to their branches; so that the whole plant, in this state, forms itself, from a very complexly branched figure, into a sort of straight cylindrical one.

Many attempts have been made to account for the motion of this plant upon mechanical principles: but all these attempts have hitherto proved unsatisfactory.

MIMULUS, in botany, a genus of the didynamia angiospermia class. The calix is prismatical, and consists of four teeth; the corolla is ringent, having the edges of the upper lip bent downwards; and the capsule has two cells, containing many seeds. There are two species, both natives of America.

MIMUSOPS, in botany, a genus of the oscandria monogynia class. The calix consists of eight leaves, and the corolla of eight petals; and the stigma is pointed.

There are two species, both natives of India.

MINA, in Grecian antiquity, a money of account, equal to an hundred drachms.

MIND, a thinking intelligent being, otherwise called spirit, in opposition to matter or body.

The culture of the human mind is more immediately taught in the sciences of logic and metals. See **LOGIC** and **MORALS**.

MINDANAO, the largest of the Philippine islands, except Luconia, is situated between 120° and 126° east longitude, and between 5° and 10° N. lat.

MUNDELHEIM, a city of Germany, thirty-three miles south east of Ulm. It is the capital of the principality of Mundelheim, conferred on the duke of Morleborough, by the emperor in 1704.

MINDEN, a city of Germany, the capital of a duchy

of the same name, situated forty miles west of Hanover.

MINDORA, one of the Philippine islands, lies south-west of Luconia, from which it is separated by a narrow channel.

MINE, in natural history, a place under ground, where metals, minerals, or even precious stones are dug up.

As, therefore, the matter dug out of mines is various, the mines themselves acquire various denominations, as gold mines, silver mines, copper mines, iron mines, diamond mines, salt mines, mines of antimony, of alum, &c.

Mines, then, in general, are veins or cavities within the earth, whose sides receding from, or approaching nearer to each other, make them of unequal breadths in different places, sometimes forming larger spaces which are called holes: they are filled with substances, which, whether metallic or of any other nature, are called the loads; when the substances forming these loads, are reducible to metal, the loads are by the miners said to be alive, otherwise they are called dead loads. In Cornwall and Devon, the loads always hold their course from eastward to westward; though in other parts of England, they frequently run from north to south. The miners report, that the sides of the load never bear in a perpendicular, but constantly under-ly either to the north or to the south. The load is frequently intercepted by the crossing of a vein of earth, or stone, or some different metallic substance; in which case it generally happens that one part of the load is moved a considerable distance to the one side. This transient load is by the miners called flooking; and the part of the lead which is to be moved, is said to be heaved.

According to Dr Nicols's observations upon mines, they seem to be, or to have been, the channels thro' which the waters pass within the earth, and, like rivers, have their small branches opening into them, in all directions. Most mines have streams of water running through them: and when they are found dry, it seems to be owing to the waters having changed their course, as being obliged to it, either because the load has stopped up the ancient passages, or that some new and more easy one is made.

Mines, says Dr Shaw, are liable to many contingencies; being sometimes poor, sometimes soon exhaurible, sometimes subject to be drowned, especially when deep, and sometimes hard to trace; yet there are many instances of mines proving highly advantageous for hundreds of years: the mines of Potosi are to this day worked with nearly the same success as at first; the gold mines of Cremnitz have been worked almost these thousand years; and our Cornish tin mines are extremely ancient. The neat profit of the silver alone, dug in the Misnian silver mines in Saxony, is still, in the space of eight years, computed at a thousand six hundred and forty four millions, besides seventy-three tons of gold. Many mines have been discovered by accident: a torrent first laid open a rich vein of the silver mine at Eriburg in Germany; sometimes a violent

violent wind, by blowing up trees, or overturning the parts of rocks, has discovered a mine; the same has happened by violent showers, earthquakes, thunder, the firing of woods, or even the stroke of a ploughshare or horse's hoof.

But the art of mining does not wait for these favourable accidents, but directly goes upon the search and discovery of such mineral veins, ores, or sands, as may be worth the working for metal. The principal investigation and discovery of mines depend upon a particular sagacity, or acquired habit of judging from particular signs, that metallic matters are contained in certain parts of the earth, not far below its surface. The principal signs of a latent metallic vein, seem reducible to general heads; such as, 1. The discovery of certain mineral waters. 2. The discolouration of the trees or grafs of a place. 3. The finding of pieces of ore on the surface of the ground. 4. The rise of warm exhalations. 5. The finding of metallic sands, and the like. All which are so many encouragements for making a stricter search near the places where any thing of this kind appears; whence rules of practice might be formed for reducing this art to a greater certainty. But when no evident marks of a mine appears, the skilful mineralist usually bores into the earth, in such places as from some analogy of knowledge, gained by experience, or by observing the situation, course, or nature of other mines, he judges may contain metal.

After the mine is found, the next thing to be considered, is whether it may be dug to advantage. In order to determine this, we are duly to weigh the nature of the place, and its situation, as to wood, water, carriage, healthiness, and the like; and compare the result with the richness of the ore, the charge of digging, stamping, washing, and smelting.

Particularly the form and situation of the spot should be well considered. A mine must either happen, 1. In a mountain. 2. In a hill. 3. In a valley. Or, 4. In a flat. But mountains and hills are dug with much greater ease and convenience, chiefly because the drains and burrows, that is, the adits or avenues, may be here readily cut, both to drain the water and to form gang-ways for bringing out the lead, &c. In all the four cases we are to look out for the veins which the rains, or other accidental thing, may have laid bare; and if such a vein be found, it may often be proper to open the mine at that place, especially if the vein prove tolerably large and rich: otherwise the most commodious place for situation is to be chose for the purpose, *viz.* neither on a flat, nor on the tops of mountains, but on the sides. The best situation for a mine, is a mountainous, woody, wholesome spot; of a safe easy ascent, and bordering on a navigable river. The places abounding with mines are generally healthy, as standing high, and every where exposed to the air; yet some places, where mines are found, prove poisonous, and can, upon no account, be dug, though ever so rich: the way of examining a suspected place of this kind, is to make experiments upon brutes, by

exposing them to the effluvia or exhalations, to find the effects.

Devonshire and Cornwall, where there are a great many mines of copper and tin, is a very mountainous country, which gives an opportunity in many places to make adits, or subterraneous drains, to some valley at a distance, by which to carry off the water from the mine, which otherwise would drown them out from getting the ore. These adits are sometimes carried a mile or two, and dug at a vast expence, as from 2000 l. to 4000 l. especially where the ground is rocky; and yet they find this cheaper than to draw up the water out of the mine quite to the top, when the water runs in plenty, and the mine is deep. Sometimes, indeed, they cannot find a level near enough, to which an adit may be carried from the very bottom of the mine; yet they find it worth while to make an adit at half the height to which the water is to be raised, thereby saving half the expence.

The late Mr Coltar, considering that sometimes from small streams, and sometimes from little springs, or collections of rain-water, one might have a pretty deal of water above ground, though not a sufficient quantity to turn an overshot-wheel, thought, that if a sufficient fall might be had, this collection of water might be made useful in raising the water in a mine to the adit, where it may be carried off.

MINE, in the military art, denotes a subterraneous canal, or passage, dug under the wall or rampart of a fortification, intended to be blown up by gun-powder.

The alley or passage of a mine is commonly about four feet square; at the end of this is the chamber of the mine, which is a cavity about five feet in width and in length, and about six feet in height; and here the gun-powder is stowed. The fauce of the mine, is the train, for which there is always a little aperture left. There are various kinds of mines, which acquire various names, as royal mines, serpentine mines, forked mines, according as their passages are straight, oblique, winding, &c.

MINEHEAD, a borough and port town of Somersetshire, which sends two members to parliament: W. long. 3° 20', N. lat. 51° 18'.

MINERAL, in natural history, is used, in general, for all fossil bodies, whether simple or compound, dug out of a subterraneous mine, from which it takes its denomination.

MINERAL Waters, in medicine, all those wherein any medicinal virtues, besides those of common water, are found.

These mineral waters are of various kinds, but they are considered under the general titles of chalybeate, purgative, and alterative. The more useful and commodious additions for examining these three kinds of mineral waters, are, according to Dr Shaw, galls, syrup of violets, and oil of tartar per deliquium. Galls discover in them any small proportion of vitriol or dissolved iron, as having the property of immediately striking a purple or black colour in all waters where any such substance is lodged. Spirit of violet, in the same

fame manner, discovers any small predominancy of an acid or alkali therein; by changing the water red if acid, and green if alkali prevails. Oil of tartar discovers any small proportion of earthy matter less capable of dissolving in water than that salt, by precipitating such earthy matter in form of a white cloud to the bottom of the containing glass, where it collects and appears like a subtle white powder.

These particulars may be shewn, and proved satisfactorily, by adding to pure water a little of a known acid, alkali, dissolved iron, and subtle earth, or fine light sediment of an earthy water; applying the syrup of violets, galls, and oil of tartar respectively.

Mineral waters are imitable by art. The rule is, by a proper analysis to find the contents of such water (by evaporation, the addition of tinging ingredients, &c. as above mentioned) and their proportions; then, by means of synthetical chemistry, to compose a similar mixture: thus, for example, we learn by a proper analysis, that the ingredients, or different constituent parts of Pyrmont waters, are a subtle aqueous fluid, a volatile iron, and a predominating alkali, all joined together in one brisk pungent spirituous water. The imitation of this kind of chalybeate water, is by much the most difficult, and may perhaps be rendered most perfect, by boiling the purest common water in a close vessel, with a small proportion of ochre, soft iron ore, or pyrites.

The imitation of the common purgative mineral waters is easy: thus Epsum water is imitated by barely dissolving three or four drams of Epsum salt in a quart of pure water, made somewhat brisk or quick with a few drops of spirit of vitriol and oil of tartar per deliquium, so as to let the alkali prevail.

The imitation of the alterative waters, such as those of Bath, Buxton, &c. has hitherto scarce been attempted, nor can be rationally, for want of their respective just analysis, upon which such imitation should always be grounded.

As to the use of mineral waters, the learned Heister observes, that in general they are found to agree much better with persons in the middle stages of life, than with persons very old or very young. If any general rule can be given in this case, it is, that people should not take them when younger than eighteen, or older than sixty.

MINERVALIA, in Roman antiquity, festivals celebrated in honour of Minerva, in the month of March; at which time the scholars had a vacation, and usually made a present to their masters, called, from this festival, *minerval*.

MINHO, a great river of Spain, which taking its rise in Galicia, divides that province from Portugal, and falls into the Atlantic at Caminha.

MINIATURE, a delicate kind of painting, distinguished from all others by the smallness of the figures, its being performed with dots or points instead of lines; by the faintness of the colouring; its requiring to be viewed very near; and by its being usually done on vellum.

This is the nicest and most tedious of all kinds of
VOL. III. No. 79. 2

painting, being performed wholly with the point of the pencil: for when the colours are laid on flat without dotting, though the figures be small, and the ground either vellum or paper, it is not called painting in miniature, but washing.

There are some painters who never use any white colour in painting in miniature, but make the ground of the vellum serve to raise their figures; in which case the lights appear bright in proportion to the depth and strength of the colours of the figures. Others, before they go to work, give the vellum a light wash with white lead well prepared and purified. These colours that have the least body, are the best and most commodious for painting in miniature; as carmine, ultramarine, fine lakes, and greens made of herbs and flowers: but besides these, the following colours are also made use of, *viz.* vermilion, black lead, brown red, masticote pale, yellow masticote, indigo, ivory black, lamp black, Spanish brown, amber, gall stone, brown ochre, French pink, orpiment, gamboge, Naples yellow, bladder-green, verditer, sea-green, German albes, flake white, and white lead. All terrene colours, and other gross substances, are too coarse for fine work, how well soever they may be ground: but the finest particles may be separated by tempering the colour in a cup of fair water; and having stirred it well with your finger, and the whole being thoroughly mixed, let it subside for a while, and then pour it by inclination into a shell that has been well scoured in hot water, and let it stand to dry. Yellow ochre, brown red, amber, and ultramarine, purify by fire; but if they are burnt in too fierce a fire, they change, and the brown red turns yellow, the yellow ochre and amber turn reddish, and so of the rest: if the fire is not too fierce, it renders them softer and kinder than before, so that the finest and purest ultramarine, burnt in a red hot shovel, becomes much more brilliant than it was before it was burnt. Greens, blacks, greys, and yellows, on being mixed with a little of the gall of the ox, carp, or eel, especially of the last, acquire a lustre and vivacity not natural to them. You must take the galls of eels, and hang them on a nail to dry; and when you use any, steep it in brandy, and mingle some of it with the colour already tempered with gum-water wherein is a little sugar-candy. When you begin to paint, the colours must be placed on a small ivory pallet of the size of your hand, in the middle of which should be placed the white, well spread out, and nearer it the lighter, and further off those darker colours you are going to use.

Your vellum must be glued to a copper-plate, or a piece of thin board, exactly of the same size with the intended piece; in doing which, the fair side of the vellum should be moistened with a fine wet linen; and a piece of white paper being put upon the back of it, it is to be applied to the plate or board, and stretching it upon it equally in all directions, the vellum, which ought to be every way a finger's-breadth larger than what you glue it to, in order to be doubled over and glued behind. When your piece is sketched out upon the vellum with a pencil, you must, with a little thin carmine, run over all the strokes that they may not be defaced in working; and this done, clean your vellum with crumb of bread. In laying on the colours, begin with sketching or drawing with large,
T 3 R bulb,

bold, but clear strokes, like those who paint in oil; your lights must at first be something brighter, and your shades not quite so dark as is required in finishing; be-
 cascade in stripping upon them you strengthen the colour, which, if too deep at first, would in finishing become too dark. Endeavour also to drown your colours into each other, that no line of separation may be seen between them: to this purpose, soften your strokes with the colours on each side of them, so that they may be blended and confounded with each other. There are several ways of stripping, and every painter has his manner: some do it with round points, others make them longish; others again hath fine strokes, crossing each other in all directions, till the whole appears as if stripped or wrought with points: this last method is the best, boldest, and soonest perfected: the artist should here accustom himself to be rich, mellow, and soft in his work; the points must seem in a manner lost in the ground they are wrought upon, and appear but just enough to shew that the piece is stripped. When the work seems finished, heightening it a little has a fine effect; that is, strengthening the lights with touches of a paler colour than at first, which must be softened away into the rest.

For laces, point, and the like, lay on first a mixture of blue, black, and white, as for linens; and then heighten the pattern, flowers or flourishes, with white only; then shade and finish with the first colour. When they are upon flesh, or any thing else which you would have seen through them, finish what is under them, as if you intended to lay nothing upon it, and then lay on the lace or point with pure white, and finish with the other mixture. In painting a fur, lay on a ground as for drapery, according to the colours of it, and then shade by the same rule; and having done, instead of stripping, draw fine strokes this way and that, according as the down of the fur you imitate lies: heighten the lights of a brown fur with ochre and white, and those of a light fur with white and a little blue.

There are several sorts of grounds for pictures and portraits: some are quite brown, with Spanish brown, umber, &c. with a little black and white; others are more yellow, being mixed with a good deal of ochre; others are upon the grey, with indigo; and others are blue or crimson.

To make a ground all of glory, first lay a bright mixture of a little ochre and white, adding more and more of the first, as you draw more and more towards the extremities of the intended picture; and when the ochre happens not to be dark enough (for you must go on darkening and darkening,) add gall-stone, then carmine, and at last Spanish brown. This ground you must lay in such a manner, that the different degrees of darkness may, as much as possible, insensibly increase and strengthen: the whole must then be stripped with the same colours.

For a day-sky, mingle some ultramarine with a good deal of white, and lay it on as smooth and uniform as possible with a large pencil and broad strokes, laying it on paler and paler as you descend towards the horizon, which must be made of vermilion, mine-de-plumb and

white, of the strength that finishes the sky, or rather a little weaker, artfully blending the blue and red, mingling at last gall-stone and a good deal of white; and all this must be so laid on that no separation must be seen between the colours. When there are to be clouds in the sky, you need lay on no blue where they are to be; but sketch them out, if they are reddish, with vermilion, gall-stone, and white, together with a little indigo; and if they are to be darker, a great deal must be used of this last, making the lights of the one and the other with mallicoet, vermilion, and white, according to the degree of strength you would give them, swelling out the whole with stripping; and if the sky be not sufficiently uniform, you must strippe that likewise.

MINIM, in music, a note equal to two crotchets, or half a semibreve. See MUSIC.

MINIMUM, in the higher geometry, the least quantity attainable in a given case.

MINISTER, a person who preaches, performs religious worship in public, administers the sacraments, &c.

MINISTERS, in Scots law. See LAW, Tit. 5.

MINISTER of state, a person to whom a sovereign prince intrusts the administration of the government.

Foreign MINISTER, is a person sent into a foreign country, to manage the affairs of his province, or of the state to which he belongs. Of these there are two kinds; those of the first rank are ambassadors and envoys extraordinary, who represent the persons of their sovereigns. The ministers of the second rank are the ordinary residents. See EMBASSADOR.

MINIUM, or RED-LEAD. See CHEMISTRY, p. 84. and 136.

MINOR, in Scots law. See LAW, Tit. 7.

MINOR, in logic, the second proposition of a regular syllogism. See LOGIC.

MINORCA, an island in the Mediterranean, about twenty miles east of Majorca, thirty miles long, and twelve broad. It is subject to Great Britain, and only valued for its capacious harbour of Port Mahon.

MINOTAUR, in antiquity, a fabulous monster much talked of by the poets, feigned to be half man and half bull.

The minotaur was brought forth by Pasiphae, wife of Minos, king of Crete. It was shut up in the labyrinth of that island, and at last killed by Theseus.

Servius gives the explanation of this fable: he says that a secretary of king Minos, named Taurus, bull, having an intrigue with the queen Pasiphae, in the chamber of Dædalus, she was at length delivered of twins; one of whom resembled Minos, and the other Taurus. This occasioned the production to be reputed monstrous.

MINSTREL, an ancient term for a fiddler, or player on any other kind of musical instrument.

MINT, the place in which the king's money is coined. See COINAGE.

There were anciently mints in almost every county in England; but the only mint at present in the British dominions, is that in the Tower of London. The officers of the mint are, 1. The warden of the mint, who is chief; he oversees the other officers, and receives the bullion. 2. The master worker; who receives the bullion

bullion from the market, causes it to be melted, delivers it to the moneyers, and when it is coined receives it again. 3. The comptroller, who is the overseer of all the inferior officers, and sees that all the money is made to the just assize. 4. The assay-master; who weighs the gold and silver, and sees that it is according to the standard. 5. The auditor; who takes the accounts. 6. The surveyor of the melting; who after the assay master has made trial of the bullion, sees that it is cast out, and not altered after it is delivered to the melter. 7. The engraver; who engraves the stamps and dyes for the coinage of the money. 8. The clerk of the irons; who sees that the irons are clean and fit to work with. 9. The melter; who melts the bullion before it is coined. 10. The provost of the mint; who provides for, and oversees all the moneyers, 11. The blanchers; who anneal and cleanse the money. 12. The moneyers; some of whom forge the money, some hear it, some round and mill it, and some stamp or coin it. 13. The porters; who keep the gate of the mint.

MINT, in botany. See **MENTHA**.

MINUARTIA, in botany, a genus of the triandria trigynia class. The calix consists of five leaves; it has no corolla; and the capsule has one cell and three valves. There are three species, all natives of Spain. **MINUET**, in music, a very graceful kind of dance; which consists of a coupe, a high step, and a balance; it begins with a beat, and its motion is triple.

MINUTE, in geometry, the sixtieth part of a degree of a circle. See **ASTRONOMY**, **GEOGRAPHY**, **GEOMETRY**.

MINUTE of time, the sixtieth part of an hour.

MINUTE, in architecture, usually denotes the sixtieth, sometimes the thirtieth part of a module. See **ARCHITECTURE**.

MINUTE is also used for a short memoir, or sketch of a thing, taken in writing.

MIRABILIS, **MARVEL OF PERU**, in botany, a genus of the pentandria monogynia class. The corolla is funnel shaped; the calix is below the fruit; and the nectarium is globular, including the germen. There are three species, all natives of America.

Tournefort and Linnaeus will have the root of this plant to be the jalap of the shops; but Houslon declares, that jalap is the root of a species of convolvulus.

MIRACLE, is a work effected in a manner different from the common and regular method of providence, by the interposition either of God himself, or some intelligent agent superior to man.

MIRALETUS, in ichthyology. See **RAJA**.

MISCHNAH, or **MISHNAH**, the code or collection of the civil law of the Jews. The Jews pretend, that when God gave the written law to Moses, he gave him also another not written, which was preserved by tradition among the doctors of the synagogue, till rabbi Judah, surnamed the Holy, seeing the danger they were in, through their dispersion, of departing from the traditions of their fathers, judged it proper to reduce them to writing.

The mishnah is divided in six parts: the first relates to the distinction of seeds in a field, to trees, fruits,

rythes, &c. The second regulates the manner of observing festivals: the third treats of women, and matrimonial cases: the fourth of losses in trade, &c.: the fifth is on obligations, sacrifices, &c.: and the sixth treats of the several sorts of purification.

MISDEMEANOUR, in law, signifies a heinous offence or fault, particularly in the execution of an office.

MISFEASANCE, in law-books, signifies a trespass.

MISLETOE, in botany. See **VISCUM**.

MISNOMER, in law, a misnaming, or mistaking a person's name. The Christian name of a person should always be perfect, but the law is not so strict and precise in regard to surnames, a small mistake in which will be dispensed with to make good a contract, and support the act of the party.

MISPRISION signifies, in general, some neglect or oversight; as where a person is privy to a treason or felony committed by another, and neglects to reveal it to the king or his council, or to a magistrate; but entirely conceals it: this is called misprision of those crimes. In cases of misprision of treason, the offender is to be imprisoned for life, and to forfeit his goods and chattels, together with the profits of his lands, &c. but in misprision of felony, the offender is only to be punished with fine and imprisonment, and to remain in prison till the fine is paid.

MISSAL, the Romish m.s.-book, containing the several masses to be said on particular days.

MISSAL BIRD. See **TURDUS**.

MISSIONARIES, such ecclesiastics as are sent by any Christian church, into pagan or infidel countries, to convert the natives, and establish the Christian religion among them.

MISUSER, in law, signifies some abuse of any particular liberty or benefit.

MISY, in natural history, a species of the chalcantha, a fossil very common in the Turkish dominions, and sometimes found in the mines at Cremnitz in Hungary.

It is a considerably firm substance, of an irregular texture, not compact, much resembling some of our more gaudy marcasites, but wanting in their hardness and weight. It is of no determinate shape or size, but it is oftentimes found in small detached masses, which are usually broad, flat, and very rugged at the edges. As to its medical virtues, they are no other than those of the green vitriol.

MITCHELLA, in botany, a genus of the tetrandria monogynia class. The corolla consists of one petal; it has four stigmata; and the berry is biseid, containing four seeds. There is but one species, a native of Carolina.

MITE, a small coin formerly current, equal to about one third part of a farthing.

MITE, in zoology. See **ACARUS**.

MITELLA, in botany, a genus of the decandria digynia class. The calix consists of five segments, the corolla of five pinnatifid petals inserted into the calix, and the capsule of two equal valves. There are two species, none of them natives of Britain.

MITRALES VALVULÆ. See **ANATOMY**, p. 279.

MITRE, a sacerdotal ornament worn on the head by bishops and certain abbots on solemn occasions; being a

sort.

sort of cap, pointed, and cleft at top. The high-priest among the Jews wore a mitre or bonnet on his head. The inferior priests among the Jews had likewise their mitres, but in what respect they differed from that of the high-priest is uncertain. Some contend that the ancient bishops wore mitres, but this is by no means certain.

MITREOLA, in botany. See *OPHIORHIZA*.

MITTAU, the capital of the duchy of Courland, in Poland: situated in E. long. 24°, N. lat. 56° 40'.

MITTIMUS, as generally used, hath two significations.

1. It signifies a writ for removing and transferring of records from one court to another.
2. It signifies a precept, or command in writing under the hand and seal of a justice of the peace, directed to the gaoler or keeper of some prison, for the receiving and safe-keeping of an offender charged with any crime until he be delivered by due course of law.

MIXT, or **MIXT BODY**, in chemistry, that which is compounded of different elements or principles. See *CHEMISTRY*.

MIXTURE, a compound, or assemblage of several different bodies in the same mass. See *CHEMISTRY*.

MIZEN, in the sea-language, is a particular mast or sail. The mizen mast stands in the sternmost part of the ship. In some great ships there are two of these; when that next the main-mast is called the main-mizen, and that next the poop the bonaventure-mizen.

MNIUM, in botany, a genus of the cryptogamia musci class. The anthra is operculated; and the capitulum of the female is naked, and dusky. There are 18 species, 7 of which are natives of Britain.

Perpetual **MOBILE**, or **MOVEMENT**. See *MOVEMENT*.

MOCO, or **MOCHO**, a great city and port-town of Arabia Felix, situated near the straits of Babelmandel, at the entrance of the Red Sea: E. long. 45°, N. lat. 13°.

MODBURY, a market-town of Devonshire, 32 miles south-west of Exeter.

MODE, in metaphysics, denotes the manner of a thing's existence. See *METAPHYSICS*, p. 179.

MODE, in music, is defined to be a particular manner of constituting the octave; or, it is the melodious constitution of the octave, as it consists of seven essential sounds, besides the key or fundamental.

A mode, then, is the particular order of the concinnous degrees of an octave; the fundamental note whereof may be called the key, as it signifies that principal note which regulates the rest.

MODEL, in a general sense, an original pattern, proposed for any one to copy or imitate.

This word is particularly used, in building, for an artificial pattern made in wood, stone, plaster, or other matter, with all its parts and proportions, in order for the better conducting and executing some great work, and to give an idea of the effect it will have in large. In all great buildings, it is much the surest way to make a model in relievio, and not to trust to a bare design or draught.

MODENA, a duchy of Italy, bounded by Mantua on the north, by Romania on the east, by Tuscany and Lucca on the south, and by Parma and the territory of Genoa on the west.

MODENA, the capital of the duchy of that name, situated in 11° 20' E. long. and 44° 45' N. lat.

MODERATOR, in the schools, the person who presides at a dispute, or in a public assembly: thus the president of the annual assembly of the church of Scotland, is styled moderator.

MODERN, in a general sense, something new, or of our time, in opposition to what is antique or ancient.

MODICA, a town of Sicily, in the province of Noto, twenty-five miles south of Syracuse.

MODIFICATION, in philosophy, that which modifies a thing, or gives it this or that manner of being.

Quantity and quality are accidents which modify all bodies.

Decree of MODIFICATION, in Scots law, a decree ascertaining the extent of a minister's stipend, without proportioning it among the persons liable in payment. See *LAW*, Tit. v. 13.

MODILLIONS, in architecture, ornaments in the cornice of the Ionic, Corinthian, and Composite columns. See *ARCHITECTURE*.

MODIUS, in antiquity, a kind of dry measure, in use among the Romans, for several sorts of grain.

MODULATION, in music, the art of keeping in, or changing the mode or key.

MODULE, in architecture, a certain measure or bigness, taken at pleasure, for regulating the proportions of columns, and the symmetry or disposition of the whole building. Architects generally chuse the semi-diameter of the bottom of the column for their module, and this they subdivide into parts or minutes. See *ARCHITECTURE*.

MOHERINGIA, in botany, a genus of the octandria digynia class. The calix has 4 leaves, and the corolla 4 petals, and the capsule consists of one cell and 4 valves. There is but one species, a native of Switzerland.

MOFFAT, a village in the shire of Annandale, thirty-six miles south-west of Edinburgh; famous for its mineral wells, one of which is used for bathing, and the water of the other is taken inwardly. These waters are of great service in grippings of the guts, colics, and pains in the stomach. Those who are troubled with obstructions, rheumatic pains, and aches, find great relief both from bathing and drinking; nor is this water a less sovereign remedy in scorbutic cases, and the king's evil. These wells, in the opinion of Dr Plummer, professor of medicine in the university of Edinburgh, owe their virtues to a sulphureous principle.

MOGULS, or **MONGOLS**, hoards or tribes of vagrant Tartars, on the north of India, from whom the moguls or sovereigns of India, as well as of the Usbec-Tartars, are descended.

MOHAIR, in commerce, the hair of a kind of goat, frequent about Angoura, in Turkey; the inhabitants of which city are all employed in the manufacture of camlets, made of this hair.

MOHAWK COUNTRY, a part of North America, inhabited by one of the five nations of the Iroquois, situated between the province of New York and the lake Ontario or Frontignac.

MOHILA,

MOHILA, one of the Comora-islands in the Indian ocean, situated between Madagascar and the continent of Africa: E. long. $43^{\circ} 30'$, S. lat. 12° .

MOIDORE, a Portuguese gold coin, value 11. 7s. Serling.

MOIETY, the half of any thing.

MOLA, in geography, a town of Italy, seven miles east of the city of Barri, in the kingdom of Naples.

MOLA, in ichthyology. See **TETRODON**.

MOLARES, or **DENTES MOLARES**, in anatomy, the large teeth called in English grinders. See **ANATOMY**, p. 165.

MOLDAVIA, a province of European Turkey, separated from Poland by the river Neister.

MOLE, in zoology. See **TALPA**.

MOLE CRICKET. See **GRYLUS**.

MOLE, in midwifery, a mass of fleshy matter, of a spherical figure, generated in the uterus, or womb, and sometimes mistaken for a child. See **MIDWIFERY**.

MOLE, in geography, a river in Surry, so called from its running, for part of its course, under ground.

MOLE, is also a massive work of large stones laid in the sea by means of cofferdams; extending before a port, either to defend the harbour from the impetuosity of the waves, or to prevent the passage of ships without leave.

ACTION OF MOLESTATION, in Scots law. See **LAW**, Tit. xxx. 19.

MOLLUGO, in botany, a genus of the triandria-trigynia class. The calix consists of five leaves; the corolla is wanting; and the capsule has three cells and three valves. There are five species, none of them natives of Britain.

MOLLOSSES, in commerce, the thick fluid matter remaining after the sugar is made, resembling syrup.

In Holland molosses are much used in the manufacture of tobacco, and by the poor people for fagar. A brandy is also distilled from them, but it is said to be unwholesome.

MOLOSSUS, in Greek and Latin poetry, a foot composed of three long syllables, as *delectant*.

MOLUCCA-ISLANDS, five islands in the Indian ocean, the largest of which is scarce thirty miles round; they are called Bachian, Machian, Motyr, Ternate, and Tydor; they produce fago, oranges, lemons, and some other fruits; but what is peculiar to these islands, is their producing cloves. They are subject to the Dutch, and are situated in 125° of east longitude, and between $50'$ south, and 2° north latitude.

MOLUCELLA, in botany, a genus of the didynamia gymnospermia class. The calix is bell-shaped, and larger than the corolla. There are three species, none of them natives of Britain.

MOLWITZ, a town of Silesia, in the kingdom of Bohemia: E. long. $16^{\circ} 45'$, N. lat. $50^{\circ} 26'$.

MOLYBDIA, in natural history, the name of a genus of crystals, of a cubic form, or composed of six sides, at right angles, like a dye.

MOMBASA, or **MONBASA**, an island and city on the east coast of Africa, opposite to the country of Mombaza, in Zanguebar: E. long. 48° , N. lat. 4° .

MOMENT, in the doctrine of time, an instant, or the most minute and indivisible part of duration.

MOMENTUM, in mechanics, signifies the same with impetus, or the quantity of motion in a moving body;

which is always equal to the quantity of matter multiplied into the velocity; or, which is the same thing, it may be considered as a rectangle under the quantity of matter and velocity.

MOMORDICA, in botany, a genus of the monœcia syngenesia class. The calix of the male and female consists of five segments; the corolla of the male has six segments; and the filaments are three. The corolla of the female consists of five segments; and it has three styli. There are eight species, none of them natives of Britain.

MONA, an island in the Baltic, south west of the island of Zealand, subject to Denmark: E. long. $12^{\circ} 30'$, N. lat. $55^{\circ} 20'$.

MONADELPHIA, in botany. See **BOTANY**, p. 635.

MONAGHAN, a county of Ireland, in the province of Ulster, bounded by Tyrone, on the north; by Armagh, on the east; by Caven and Louth, on the south; and by the county of Fermanagh, on the west.

MONANDRIA, in botany. See **BOTANY**, p. 635.

MONARCHY, a government in which the supreme power is vested in a single person. See **GOVERNMENT**.

MONARDA, in botany, a genus of the diandria monogynia class. The corolla is unequal, the superior lip involving a linear filament. It has four seeds. There are five species, none of them natives of Britain.

MONASTERY, a convent, or house built for the reception and entertainment of monks, mendicant friars, or nuns, whether it be an abbey, priory, &c.

Monasteries are governed by different rules, according to the different regulations prescribed by their founders. The first regular and perfect monasteries were founded by St. Pachomius, in Egypt; but St. Basil is generally considered as the great father and patriarch of the Eastern monks; since in the fourth century he prescribed rules for the government of the monasteries, to which the Anachorets and Coenobites, and the other ancient fathers of the deserts, submitted. In like manner St. Benedict was styled the patriarch of the Western monks. He appeared in Italy towards the latter end of the fifth century, and published his rule, which was universally received throughout the west. St. Augustin being sent into England by St. Gregory the pope, in the year 596, to convert the English, he at the same time introduced the monastic state into this kingdom; which made such progress here, that within the space of two hundred years, there were thirty kings and queens who preferred the religious habit to their crowns, and founded stately monasteries, where they ended their days in solitude and retirement.

MONASTIC, something belonging to monks. See **MONK**.

MONCON, a two of Spain, in the province of Aragon, fifty miles north-east of Saragossa.

MONDAY, the second day of the week, so called as being anciently sacred to the moon, *q d.* moon-day.

MONEMUGI, a country in the south of Africa, situated between Angola and Zanguebar.

MONEY, a piece of matter, commonly metal, to which public authority has affixed a certain value and weight to serve as a medium in commerce.

Of artificial or material money.

I. FROM the infancy of the world, at least as far back as our accounts of the transactions of mankind reach, we find they had adopted the precious metals, that is, silver and gold, as the common measure of value, and as the adequate equivalent for every thing alienable.

The metals are admirably adapted for this purpose: They are perfectly homogeneous: When pure, their masses, or bulks, are exactly in proportion to their weights: No physical difference can be found between two pounds of gold, or silver, let them be the production of the mines of Europe, Asia, Africa, or America: They are perfectly malleable, fusible, and suffer the most exact division which human art is capable to give them: They are capable of being mixed with one another, as well as with metals of a baser, that is, of a less homogeneous nature, such as copper: By this mixture they spread themselves uniformly through the whole mass of the composed lump, so that every atom of it becomes proportionally possessed of a share of this noble mixture; by which means the subdivision of the precious metals is rendered very extensive:

Their physical qualities are invariable; they lose nothing by keeping; they are solid and durable; and though their parts are separated by friction, like every other thing, yet still they are of the number of those which suffer least by it.

If money, therefore, can be made of any thing, that is, if the proportional value of things vendible can be measured by any thing material, it may be measured by the metals.

II. The two metals being pitched upon as the most proper substances for realizing the ideal scale of money, those who undertake the operation of adjusting a standard must constantly keep in their eye the nature and qualities of a scale, as well as the principles upon which it is formed.

The unit of the scale must constantly be the same, although realized in the metals, or the whole operation fails in the most essential part. This realizing the unit is like adjusting a pair of compasses to a geometrical scale, where the smallest deviation from the exact opening once given must occasion an incorrect measure. The metals, therefore, are to money what a pair of compasses is to a geometrical scale.

This operation of adjusting the metals to the money of account implies an exact and determinate proportion of both metals to the money unit, realized in all the species and denominations of coin, adjusted to that standard.

The smallest particle of either metal added to, or taken away from any coin, which represent certain determinate parts of the scale, overturns the whole system of material money. And if, notwithstanding such variation, these coins continue to bear the same denominations as before, this will as effectually destroy their usefulness in measuring the value of things, as it would overturn the usefulness of a pair of compasses, to suffer the opening to vary, after it is adjusted to the scale representing feet, toises, miles, or leagues, by which the distances up the plan are to be measured.

III. Debasing the standard is a good term; because it

conveys a clear and distinct idea. It is diminishing the weight of the pure metal contained in that denomination by which a nation reckons, and which we have called the money unit. Raising the standard requires no farther definition, being the direct contrary.

IV. Altering the standard (that is, raising or debasing the value of the money unit) is like altering the national measures or weights. This is best discovered by comparing the thing altered with things of the same nature which have suffered no alteration. Thus if the foot of measure was altered at once over all England, by adding to it, or taking from it, any proportional part of its standard length, the alteration would be best discovered, by comparing the new foot with that of Paris, or of any other country, which had suffered no alteration. Just so, if the pound sterling, which is the English unit, shall be found any how changed, and if the variation it has met with be difficult to ascertain, because of a complication of circumstances, the best way to discover it, will be to compare the former and the present value of it with the money of other nations which has suffered no variation. This the course of exchange will perform with the greatest exactness.

V. Artists pretend, that the precious metals, when absolutely pure from any mixture, are not of sufficient hardness to constitute a solid and lasting coin. They are found also in the mines mixed with other metals of a baser nature, and the bringing them to a state of perfect purity occasions an unnecessary expence. To avoid, therefore, the inconvenience of employing them in all their purity, people have adopted the expedient of mixing them with a determinate proportion of other metals, which hurts neither their fusibility, malleability, beauty, or lustre. This metal is called *alloy*; and, being considered only as a support to the principal metal, is accounted of no value in itself. So that eleven ounces of gold, when mixed with one ounce of silver, acquires, by that addition, no augmentation of value whatever.

This being the case, we shall, as much as possible, overlook the existence of alloy, in speaking of money, in order to render language less subject to ambiguity.

Incapacities of the metals to perform the office of an invariable measure of value.

I. WERE there but one species of such a substance as we have represented gold and silver to be; were there but one metal possessing the qualities of purity, divisibility, and durability; the inconveniences in the use of it for money would be fewer by far than they are found to be as matters stand.

Such a metal might then, by an unlimited division into parts exactly equal, be made to serve as a tolerably steady and universal measure. But the rivalry between the metals, and the perfect equality which is found between all their physical qualities, so far as regards purity and divisibility, render them so equally well adapted to serve as the common measure of value, that they are universally admitted to pass current as money.

What is the consequence of this? That the one measures the value of the other, as well as that of every other thing. Now the moment any measure begins to be measured

fared by another, whose proportion to it is not physically, perpetually, and invariably the same, all the utensils of such a measure is lost. An example will make this plain.

A foot of measure is a determinate length. An English foot may be compared with the Paris foot, or with that of the Rhine; that is to say, it may be measured by them; and the proportion between their lengths may be expressed in numbers; which proportion will be the same perpetually. The measuring the one by the other will occasion no uncertainty; and we may speak of lengths by Paris feet, and be perfectly well understood by others who are used to measure by the English foot, or by the foot of the Rhine.

But suppose that a youth of twelve years old takes it into his head to measure from time to time, as he advances in age, by the length of his own foot, and that he divides this growing foot into inches and decimals: what can be learned from his account of measures! As he increases in years, his foot, inches, and subdivisions, will be gradually lengthening; and were every man to follow his example, and measure by his own foot, then the foot of a measure now established would totally cease to be of any utility.

This is just the case with the two metals. There is no determinate invariable proportion between their value; and the consequence of this is, that when they are both taken for measuring the value of other things, the things to be measured, like lengths to be measured by the young man's foot, without changing their relative proportion between themselves, change however with respect to the denominations of both their measures. An example will make this plain.

Let us suppose an ox to be worth three thousand pounds weight of wheat, and the one and the other to be worth an ounce of gold, and an ounce of gold to be worth exactly fifteen ounces of silver: If the case should happen, that the proportional value between gold and silver should come to be as 14 is to 1, would not the ox, and consequently the wheat, be estimated at less in silver, and more in gold, than formerly? Farther, would it be in the power of any state to prevent this variation in the measure of the value of oxen and wheat, without putting into the unit of their money less silver and more gold than formerly.

If therefore any particular state should fix the standard of the unit of their money to one species of the metals, while in fact both the one and the other are actually employed in measuring value; does not such a state resemble the young man, who measures all by his growing foot? For if silver, for example, be retained as the standard, while it is gaining upon gold one fifteenth additional value; and if gold continue all the while to determine the value of things as well as silver, it is plain, that, to all intents and purposes, this silver-measure is lengthening daily, like the young man's foot, since the same weight of it must become every day equivalent to more and more of the same commodity; notwithstanding that we suppose the same proportion to subsist, without the least variation, between that commodity and every other species of things alienable.

Buying and selling are purely conventional, and no man

is obliged to give his merchandize at what may be supposed to be the proportion of its worth. The use, therefore of an universal measure, is, to mark, not only the relative value of the things to which it is applied as a measure, but to discover in an instant the proportion between the value of those, and of every other commodity valued by a determinate measure in all the countries of the world.

Were pounds sterling, livres, florins, piastres, &c. which are all money of account, invariable in their values, what a facility would it produce in all conversions, what an assistance to trade! But as they are all limited or fixed to coins, and consequently vary from time to time, this example shews the utility of the invariable measure which we have described.

There is another circumstance which incapacitates the metals from performing the office of money; the substance of which the coin is made, is a commodity, which rises and sinks in its value with respect to other commodities, according to the wants, competition, and caprices of mankind. The advantage, therefore, found in putting an intrinsic value into that substance which performs the function of money of account, is compensated by the instability of that intrinsic value; and the advantage obtained by the stability of paper, or symbolical money, is compensated by the defect it commonly has of not being at all times susceptible of realization into solid property or intrinsic value.

In order, therefore, to render material money more perfect, this quality of metal, that is, of a commodity, should be taken from it; and in order to render paper-money more perfect, it ought to be made to circulate upon metallic or land security.

II. There are several smaller inconveniences accompanying the use of the metals, which we shall here shortly enumerate.

1^{mo}. No money made of gold or silver can circulate long, without losing of its weight, although it all along preserves the same denomination. This represents the contracting a pair of compasses which had been rightly adjusted to the scale.

2^{do} Another inconvenience proceeds from the fabrication of money. Supposing the faith of Princes who coin money to be inviolable, and the probity as well as capacity of those to whom they commit the inspection of the fineness of the metals to be sufficient, it is hardly possible for workmen to render every piece exactly of a proper weight, or to preserve the due proportion between pieces of different denominations; that is to say, to make every ten sixpences exactly of the same weight with every crown-piece and every five shillings struck in a coinage. In proportion to such inaccuracies, the parts of the scale become unequal.

3^{to}. Another inconvenience, and far from being inconsiderable, flows from the expence requisite for the coining of money. This expence adds to its value as a manufacture, without adding any thing to its weight.

4^{to}. The last inconvenience is, that by fixing the money of account entirely to the coin, without having any independent common measure (to mark and control these deviations from mathematical exactness, which are either inseparable

inseparable from the metals themselves, or from the fabrication of them) the whole measure of value, and all the relative interests of debtors and creditors, become at the disposal not only of workmen in the mint, of Jews who deal in money, of clippers and washers of coin, but they are also entirely at the mercy of princes, who have the right of coinage, and who have frequently also the right of raising or debasing the standard of the coin, according as they find it most for their present and temporary interest.

Methods which may be proposed for lessening the several inconveniences to which material money is liable.

THE inconveniences from the variation in the relative value of the metals to one another, may in some measure be obviated by the following expedients.

1^{mo}. By considering one only as the standard, and leaving the other to seek its own value, like any other commodity.

2^{do}. By considering one only as the standard, and fixing the value of the other from time to time by authority, according as the market-price of the metals shall vary.

3^{io}. By fixing the standard of the unit according to the mean proportion of the metals, attaching it to neither; regulating the coin accordingly; and upon every considerable variation in the proportion between them, either to make a new coinage, or to raise the denomination of one of the species, and lower it in the other, in order to preserve the unit exactly in the mean proportion between the gold and silver.

4^{to}. To have two units, and two standards, one of gold, and one of silver, and to allow every body to stipulate in either.

5^{to}. Or last of all, to oblige all debtors to pay one half in gold, and one half in the silver standard.

Variations to which the value of the money-unit is exposed from every disorder in the coin.

LET us suppose, at present, the only disorder to consist in a want of the due proportion between the gold and silver in the coin.

This proportion can only be established by the market-price of the metals; because an augmentation and rise in the demand for gold or silver has the effect of augmenting the value of the metal demanded. Let us suppose, that to day one pound of gold may buy fifteen pounds of silver; if to-morrow there be a high demand for silver, a competition among merchants to have silver for gold will ensue; they will contend who shall get the silver at the rate of fifteen pounds for one of gold: this will raise the price of it; and in proportion to their views of profit, some will accept of less than the fifteen pounds. This is plainly a raise in the silver, more properly than a fall in the gold; because it is the competition for the silver which has occasioned the variation in the former proportion between the metals.

Let us now suppose, that a state, having with great exactness examined the proportion of the metals in the market, and having determined the precise quantity of each for realizing or representing the money-unit, shall

execute a most exact coinage of gold and silver coin. As long as that proportion continues unvaried in the market, no inconvenience can result from that quarter, in making use of metals for money of account.

But let us suppose the proportion to change; that the silver, for example, shall rise in its value with regard to gold; will it not follow, from that moment, that the unit realized in the silver, will become of more value than the unit realized in the gold coin?

But as the law has ordered them to pass as equivalents for one another, and as debtors have always the option of paying in what legal coin they think fit, will they not all chuse to pay in gold, and will not then the silver coin be melted down or exported, in order to be sold as bullion, above the value it bears when it circulates in coin? Will not this paying in gold also really diminish the value of the money unit, since upon this variation every thing must sell for more gold than before, as we have already observed?

Consequently, merchandize which have not varied in their relative value to any other thing but to gold and silver, must be measured by the mean proportion of the metals; and the application of any other measure to them is altering the standard. If they are measured by the gold, the standard is debased; if by silver, it is raised.

If, to prevent the inconvenience of melting down the silver, the state shall give up affixing the value of their unit to both species at once, and shall fix it to one, leaving the other to seek its price as any other commodity; in that case, no doubt, the melting down of the coin will be prevented; but will ever this restore the value of the money unit to its former standard? Would it, for example, in the foregoing supposition, raise the debased value of the money-unit in the gold coin, if that species were declared to be the standard? It would indeed render silver coin purely a merchandize, and, by allowing it to seek its value, would certainly prevent it from being melted down as before; because the pieces would rise conventionally in their denomination; or an agio, as it is called, would be taken in payments made in silver; but the gold would not, on that account, rise in its value, or begin to purchase any more merchandize than before. Were therefore the standard fixed to the gold, would not this be an arbitrary and a violent revolution in the value of the money unit, and a debasement of the standard?

If, on the other hand, the state should fix the standard to the silver, which we suppose to have risen in its value, would that ever sink the advanced value which the silver coin had gained above the worth of the former standard unit? and would not this be a violent and an arbitrary revolution in the value of the money unit, and a raising of the standard?

The only expedient, therefore, is, in such a case, to fix the numery unit to neither of the metals, but to contrive a way to make it fluctuate in a mean proportion between them; which is in effect the introduction of a pure ideal money of account.

The regulation of fixing the unit by the mean proportion, ought to take place at the instant the standard unit is affixed with exactness both to the gold and silver. If

it be introduced long after the market proportion between the metals has deviated from the proportion established in the coin; and if the new regulation is made to have a retrospect, with regard to the acquitting of permanent contracts entered into, while the value of the money-unit had attached itself to the lowest currency, in consequence of the principle above laid down; then the restoring the money-unit to that standard where it ought to have remained (to wit, to the mean proportion) is an injury to all debtors who have contracted since the time that the proportion of the metals began to vary.

This is clear from the former reasoning. The moment the market-price of the metals differs from that in the coin, every one who has payments to make, pays in that species which is the highest rated in the coin; consequently, he who lends, lends in that species. If after the contract, therefore, the unit is carried up to the mean proportion, this must be a loss to him who had borrowed.

From this we may perceive, why there is less inconvenience from the varying of the proportion of the metals, where the standard is fixed to one of them, than when it is fixed to both. In the first case, it is at least uncertain whether the *standard* or the *merchandise-species* is to rise; consequently it is uncertain whether the debtors or the creditors are to gain by a variation. If the *standard-species* should rise, the creditors will gain; if the *merchandise-species* rises, the debtors will gain; but when the unit is attached to both species, then the creditors never can gain, let the metals vary as they will: if silver rises, then debtors will pay in gold; if gold rises, debtors will pay in silver. But whether the unit be attached to one or to both species, the infallible consequence of a variation is, that one half of the difference is either gained or lost by debtors and creditors. The invariable unit is constantly the mean proportional between the two measures.

How the variations in the intrinsic value of the unit of money must affect all the domestic interest of a Nation.

If the changing the content of the bushel by which grain is measured, would affect the interest of those who are obliged to pay, or who are intitled to receive, a certain number of bushels of grain for the rent of lands; in the same manner must every variation in the value of the unit of account affect all persons who, in permanent contracts, are obliged to make payments, or who are intitled to receive sums of money stipulated in multiples or in fractions of that money unit.

Every variation, therefore, upon the intrinsic value of the money unit, has the effect of benefiting the class of creditors, at the expence of debtors, or *vice versa*.

This consequence is deduced from an obvious principle. Money is more or less valuable in proportion as it can purchase more or less of every kind of merchandise. Now without entering anew into the causes of the rise and fall of prices, it is agreed upon all hands, that whether an augmentation of the general mass of money in circulation has the effect of raising prices in general, or not, any augmentation of the quantity of the metals appointed to be put into the money-unit, must at least affect the value

of that money-unit, and make it purchase more of any commodity than before; that is to say, if 113 grains of fine gold, the present weight of a pound sterling in gold, can buy 113 pounds of flour; were the pound sterling raised to 114 grains of the same metal, it would buy 114 pounds of flour; consequently, were the pound sterling augmented by one grain of gold, every miller who paid a rent of ten pounds a year, would be obliged to sell 1140 pounds of his flour, in order to procure 10 pounds to pay his rent, in place of 1130 pounds of flour which he sold formerly to procure the same sum; consequently, by this innovation, the miller must lose yearly ten pounds of flour, which his master consequently must gain. From this example, it is plain, that every augmentation of metals put into the pound sterling, either of silver or gold, must imply an advantage to the whole class of creditors who are paid in pounds sterling, and consequently must be a proportional loss to all debtors who must pay by the same denomination.

Of the disorder in the British coin, so far as it occasions the melting down or the exporting of the species.

THE defects in the British coin are three.

1^{mo}. The proportion between the gold and silver in it is found to be as 1 to 15 $\frac{1}{2}$, whereas the market price may be supposed to be nearly as 1 to 14 $\frac{1}{2}$.

2^{do}. Great part of the current money is worn and light.

3^{tio}. From the second defect proceeds the third, to wit, that there are several currencies in circulation which pass for the same value, without being of the same weight.

4^{to}. From all these defects results the last and greatest inconvenience, to wit, that some innovation must be made, in order to set matters on a right footing.

The English, besides the unit of their money which they call the pound sterling, have also the unit of their weight for weighing the precious metals.

This is called the pound troy, and consists of 12 ounces, every ounce of 20 penny-weight, and every penny-weight of 24 grains. The pound troy, therefore, consists of 240 penny-weight, and 5760 grains.

The fineness of the silver is reckoned by the number of ounces and penny-weights of the pure metals in the pound troy of the composed mass; or in other words, the pound troy, which contains 5760 grains of standard silver, contains 5328 grains of fine silver, and 432 grains of copper, called alloy.

Thus standard silver is 11 ounces 2 penny-weights of fine silver in the pound troy to 18 penny-weights copper, or 111 parts fine silver to 9 parts alloy.

Standard gold is 11 ounces fine to one ounce silver or copper employed for alloy, which together make the pound troy; consequently, the pound troy of standard gold, contains 5280 grains fine, and 480 grains alloy, which alloy is reckoned of no value.

This pound of standard silver is ordered, by statute of the 43d of Elizabeth, to be coined into 62 shillings, 20 of which make the pound sterling; consequently the 20 shillings contain 1718.7 grains of fine silver, and 1838.06 standard silver.

The pound troy of standard gold, $\frac{7}{11}$ fine, is ordered

†

by

by an act of King Charles II. to be cut into $44\frac{1}{2}$ guineas; that is to say, every guinea contains 129.43 grains of standard gold, and 118.644 of fine gold; and the pound sterling, which is $\frac{20}{9}$ of the guinea, contains 112.994, which we may state at 113 grains of fine gold.

The coinage in England is entirely defrayed at the expence of the state. The mint price for the metals is the very same with the price of the coin. Whoever carries to the mint an ounce of standard silver, receives for it in silver coin 5s. 2d. or 62d: whoever carries an ounce of standard gold receives in gold coin 3*l*. 17*s*. 10*d* $\frac{1}{2}$. the one and the other making exactly an ounce of the same fineness with the bullion. Coin, therefore, can have no value in the market above bullion; consequently, no loss can be incurred by those who melt it down.

When the guinea was first struck, the government (not inclining to fix the pound sterling to the gold coin of the nation) fixed the guinea at 20 shillings, (which was then below its proportion to the silver) leaving it to seek its own price above that value, according to the course of the market.

By this regulation no harm was done to the English silver standard; because the guinea, or 118.644 grains fine gold being worth more, at that time, than 20 shillings, or 1718.7 grains fine silver, no debor would pay with gold at its standard value, and whatever it was received for above that price was purely conventional.

Accordingly guineas sought their own price until the year 1728, that they were fixed a new, not below their value as at first, but at what was then reckoned their exact value, according to the proportion of the metals, to wit, at 21 shillings, and at this they were ordered to pass current in all payments:

This operation had the effect of making the gold a standard as well as the silver. Debtors then paid indifferently in gold as well as in silver, because both were supposed to be of the same intrinsic as well as current value; in which case no inconvenience could follow upon this regulation. But, in time, silver came to be more demanded; the making of plate began to prevail more than formerly, and the exportation of silver to the East Indies increasing yearly, made the demand for it greater, or perhaps brought its quantity to be proportionally less than before. This changed the proportion of the metals; and by slow degrees they have come from that of 1 to 15.2 (the proportion they were supposed to have when the guineas were fixed and made a lawful money at 21 shillings) to that of 14.5 the present *supposed* proportion.

The consequence of this has been, that the same guinea which was worth 1804.6 grains fine silver, at the time it was fixed at 21 shillings, is now worth no more than 1709.9 grains of fine silver according to the proportion of 14 $\frac{1}{2}$ to 1.

Consequently, debtors, who have always the option of the legal species in paying their debts, will pay pounds sterling no more in silver but in gold; and as the gold pounds they pay in, are not intrinsically worth the silver pounds they paid in formerly, according to the statute of Elizabeth, it follows that the pound sterling in silver is really no more the standard, since no body will pay at that rate, and since no body can be compelled to do it.

Besides this want of proportion between the metals, the silver coined before the reign of George I. is now become light by circulation; and the guineas coined by all the Princes since Charles II. pass by tale, though many of them are considerably diminished in their weight.

Let us now examine what profit the want of proportion and the want of weight in the coin can afford to the money-jobbers, in melting it down or exporting it.

Did every body consider coin only as the measure for reckoning value, without attending to its value as a metal, the deviations of gold and silver coin from perfect exactness either as to proportion or weight would occasion little inconvenience.

Great numbers indeed, in every modern society, consider coin in no other light, than that of money of account; and have great difficulty to comprehend what difference any one can find between a light shilling and a heavy one; or what inconvenience there can possibly result from a guinea's being some grains of fine gold too light to be worth 21 shillings standard weight. And did every one think in the same way, there would be no occasion for coin of the precious metals at all; leather, copper, iron, or paper, would keep the reckoning as well as gold and silver.

But although there be many who look no farther than at the stamp on the coin, there are others whose sole business it is to examine its intrinsic worth as a commodity, and to profit of every irregularity in the weight and proportion of metals.

By the very institution of coinage, it is implied, that every piece of the same metal, and same denomination with regard to the money-unit, shall pass current for the same value.

It is, therefore, the employment of money-jobbers, to examine, with a scrupulous exactness, the precise weight of every piece of coin which comes into their hands.

The first object of their attention, is the price of the metals in the market: a jobber finds, at present, that with 14.5 pounds of fine silver bullion, he can buy one pound of fine gold bullion.

He therefore buys up with gold coin, all the new silver as fast as it is coined, of which he can get at the rate of 15.2 pounds for one in gold; these 15.2 pounds silver coin he melts down into bullion, and converts that back into gold bullion, giving at the rate of only 14.5 pounds for one.

By this operation he remains with the value of $\frac{1}{10}$ of one pound weight of silver bullion clear profit upon the 15 $\frac{1}{2}$ pounds he bought; which $\frac{1}{10}$ is really lost by the man who inadvertently coined silver at the mint, and gave it to the money-jobber for his gold. Thus the state loses the expence of the coinage, and the public the convenience of change for their guineas.

But here it may be asked, Why should the money-jobber melt down the silver coin? can he not buy gold with it as well without melting it down? He cannot; because when it is in coin, he cannot avail himself of its being new and weighty. Coin goes by tale, not by weight; therefore, were he to come to market with his new silver coin, gold bullion being sold at the mint price, we shall suppose, viz. at 3*l*. 17*s*. 10 $\frac{1}{2}$ *d*. sterling money

per ounce, he would be obliged to pay the price of what he bought with heavy money, which he can equally do with light.

He therefore melts down the new silver coin, and sells it for bullion, at 40 many pence an ounce, the price of which bullion is, in the English market, always above the price of silver at the mint, for the reasons now to be given.

When you sell standard silver bullion at the mint, you are paid in weighty money; that is, you receive for your bullion the very same weight in standard coin; the coinage costs nothing: but when you sell bullion in the market, you are paid in worn out silver, in gold, in bank notes, in short, in every species of lawful current money. Now all these payments have some defect: the silver you are paid with is worn and light; the gold you are paid with is over-rated, and perhaps also light; and the bank notes must have the same value with the specie with which the bank pays them; that is, with light silver or over-rated gold.

It is for these reasons, that silver bullion, which is bought by the mint at 5*s.* 2*d.* per ounce of heavy silver money, may be bought at market at 65 pence the ounce in light silver, over-rated gold, or bank notes, which is the same thing.

Farther, we have seen how the imposition of coinage has the effect of raising coin above the value of bullion, by adding a value to it which it had not as a metal.

Just so, when the unit is once affixed to certain determined quantities of both metals, if one of the metals should afterwards rise in value in the market, the coin made of that metal must lose a part of its value as coin, although it retains it as a metal. Consequently, as in the first case, it acquired an additional value by being coined, it must now acquire an additional value by being melted down. From this we may conclude, that when the standard is affixed to both the metals in the coin, and when the proportion of that value is not made to follow the price of the market, that species which rises in the market is melted down, and the bullion is sold for a price as much exceeding the mint price as the metal has risen in its value.

If, therefore, in England, the price of silver bullion is found to be at 65 pence the ounce, while at the mint it is rated at 62; this proves that silver has risen $\frac{3}{8}$ above the proportion observed in the coin, and that all coin of standard weight may consequently be melted down with a profit of $\frac{3}{8}$. But as there are several other circumstances to be attended to, which regulate and influence the price of bullion, we shall here pass them in review, the better to discover the nature of this disorder in the English coin, and the advantages which money-jobbers may draw from it.

The price of bullion, like that of every other merchandise, is regulated by the value of the money it is paid with.

If bullion, therefore, sells in England for 65 pence an ounce, paid in silver coin, it must sell for 65 shillings the pound troy; that is to say, the shillings it is commonly paid with do not exceed the weight of $\frac{1}{20}$ of a pound troy: for if the 65 shillings with which the pound

of bullion is paid weighed more than a pound troy, it would be a shorter and better way for him who wants bullion to melt down the shillings and make use of the metal, than to go to market with them in order to get 1*l.*

We may, therefore, be very certain, that no man will buy silver bullion at 65 pence an ounce, with any shilling which weighs above $\frac{1}{20}$ of a pound troy.

We have gone upon the supposition that the ordinary price of bullion in the English market is 65 pence per ounce. This has been done upon the authority of some late writers on this subject: it is now proper to point out the causes which may make it deviate from that value.

I. It may vary, and certainly will vary, in the price, according as the currency is better or worse. When the expences of a war, or a wrong balance of trade, have carried off a great many heavy guineas, it is natural that bullion should rise; because then it will be paid for more commonly in light gold and silver; that is to say, with pounds sterling, below the value of 113 grains fine gold, the worth of the pound sterling in new guineas.

II. This wrong balance of trade, or a demand for bullion abroad, becoming very great, may occasion a scarcity of the metals in the market, as well as a scarcity of the coin; consequently, an advanced price must be given for it in proportion to the greatness and height of the demand. In this case, both the specie and the bullion must be bought with paper. But the rise in the price of bullion proceeds from the demand for the metals, and the competition between merchants to procure them, and not because the paper given as the price is at all of inferior value to the specie. The least discredit of this kind would not tend to diminish the value of the paper; it would annihilate it at once. Therefore, since the metals must be had, and that the paper cannot supply the want of them when they are to be exported, the price rises in proportion to the difficulties in finding metals elsewhere than in the English market.

III. A sudden call for bullion, for the making of plate. A goldsmith can well afford to give 67 pence for an ounce of silver, that is to say, he can afford to give one pound of gold for 14 pounds of silver, and perhaps for less, notwithstanding that what he gives be more than the ordinary proportion between the metals, because he indemnifies himself amply by the price of his workmanship: just as a tavern keeper will pay any price for a fine fish, because, like the goldsmith, he buys for other people.

IV. The mint price has as great an effect in bringing down the price of bullion, as exchange has in raising it. In countries where the metals in the coin are justly proportioned, where all the currencies are of legal weight, and where coinage is imposed, the operations of trade make the price of bullion constantly to fluctuate between the value of the coin and the mint price of the metals.

Now let us suppose that the current price of silver bullion in the market is 65 pence the ounce, paid in lawful money, no matter of what weight, or of what metal. Upon this the money jobber falls to work. All shillings which are above $\frac{1}{20}$ of a pound troy, he throws into his melting

melting pot, and sells them as bullion, for 65*d.* *per* ounce; all those which are below that weight he carries to market, and buys bullion with them, at 65 pence *per* ounce.

What is the consequence of this?

That those who sell the bullion, finding the shillings which the money-jobber pays with perhaps not above $\frac{65}{80}$ of a pound troy, they on their side raise the price of their bullion to 66 pence the ounce.

This makes new work for the money-jobber; for he must always gain. He now weighs all shillings as they come to hand; and as formerly he threw into his melting-pot those only which were worth more than $\frac{65}{80}$ of a pound troy, he now throws in all that are in value above $\frac{65}{80}$. He then sells the melted shillings at 66 pence the ounce, and buys bullion with the light ones at the same price.

This is the consequence of ever permitting any species of coin to pass by the authority of the stamp, without controlling it at the same time by the weight: and this is the manner in which money-jobbers gain by the currency of light money.

It is no argument against this exposition of the matter to say, that silver bullion is seldom bought with silver coin; because the pence in new guineas are worth no more than the pence of shillings of 65 in the pound troy: that is to say, that 240 pence contained in $\frac{3}{4}$ of a new guinea, and 240 pence contained in 28 shillings of 65 to the pound troy differ no more in the intrinsic value than 0.88 of a grain of fine silver upon the whole, which is a mere trifle.

Whenever, therefore, shillings come below the weight of $\frac{65}{80}$ of a pound troy, then there is an advantage in changing them for new guineas: and when that is the case, the new guineas will be melted down, and profit will be found in selling them for bullion, upon the principles we have just been explaining.

We have already given a specimen of the domestic operations of the money-jobbers; but these are not the most prejudicial to national concerns. The jobbers may be supposed to be Englishmen; and in that case the profit they make remains at home: but whenever there is a call for bullion to pay the balance of trade, it is evident that this will be paid in silver coin, never in gold, if heavy silver can be got; and this again carries away the silver coin, and renders it at home so rare, that great inconveniences are found for want of the lesser denominations of it. The loss, however, here is confined to an inconvenience; because the balance of trade being a debt which must be paid, we do not consider the exportation of the silver for that purpose as any consequence of the disorder of the coin. But besides this exportation which is necessary, there are others which are arbitrary, and which are made only with a view to profit of the wrong proportion.

When the money jobbers find difficulty in carrying on the traffic we have described, in the English market, because of the competition among themselves, they carry the silver coin out of the country, and sell it abroad for gold, upon the same principles that the East India company send silver to China, in order to purchase gold.

It may be demanded, what hurt this trade can do to

England, since those who export silver bring back the same value in gold? Were this trade carried on by natives, there would be no loss; because they would bring home gold for the whole intrinsic value of the silver. But if we suppose foreigners sending over gold to be coined at the English mint, and changing that gold into English silver coin, and then carrying off this coin, it is plain that they must gain the difference, as well as the money jobbers. But it may be answered, that having given gold for silver at the rate of the mint, they have given value for what they have received. Very right; but so did Sir Hans Sloane, when he paid five guineas for an overgrown tod: he got value for his money; but it was value only to himself. Just so, whenever the English government shall be obliged to restore the proportion of the metals, (as they must do,) this operation will annihilate that imaginary value which they have hitherto set upon gold; which imagination is the only thing which renders the exchange of their silver against the foreign gold equal.

But it is farther objected, that foreigners cannot carry off the heavy silver; because there is none to carry off. Very true; but then they have carried off a great quantity already: or if the English Jews have been too sharp to allow such a profit to fall to strangers, (which may or may not have been the case,) then this disorder is an effectual stop to any more coinage of silver for circulation.

Of the disorder in the British coin, so far as it affects the value of the pound sterling currency.

FROM what has been said, it is evident, that there must be found in England two legal pounds sterling, of different values; the one worth 112 grains of fine gold, the other worth 1718.7 grains of fine silver. We call them different; because these two portions of the precious metals are of different values all the over Europe.

But besides these two different pounds sterling, which the change in the proportion of the metals have created, the other defects of the circulating coin produce similar effects. The guineas coined by all the Princes since K. Charles II. have been of the same standard weight and fineness, $4\frac{1}{2}$ in a pound troy of standard gold $\frac{1}{12}$ fine: these have been constantly wearing ever since they have been coined; and in proportion to their wearing they are of less value.

If, therefore, the new guineas are below the value of a pound sterling in silver standard weight, the old must be of less value still. Here then is another currency, that is, another pound sterling; or indeed, more properly speaking, there are as many different pounds sterling, as there are guineas of different weights. This is not all; the money jobbers having carried off all the weighty silver, that which is worn with use, and reduced even below the standard of gold, forms one currency more, and totally destroys all determinate proportion between the money unit and the currencies which are supposed to represent it.

It may be asked, how, at this rate, any silver has remained in England? It is answered, that the few weighty shillings which still remain in circulation, have marvelously escaped the hands of the money jobbers; and as for the rest, the rubbing and wearing of these pieces has

done

done what the state might have done; that is to say, it has reduced them to their due proportion with the lightest gold.

The disorder, therefore, of the English coin has rendered the standard of a pound sterling quite uncertain. To say that it is 1718.7 grains of fine silver, is quite ideal. Who are paid in such pounds? To say that it is 113 grains of pure gold, may also not be true; because there are many currencies worse than the new guineas.

What then is the consequence of all this disorder? What effect has it upon the current value of a pound sterling? And which way can the value of that be determined?

The operations of trade bring value to an equation, notwithstanding the greatest irregularities possible, and so in fact a pound sterling has acquired a determinate value over all the world by the means of foreign exchange. This is a kind of ideal scale for measuring the British coin, although it has not all the properties of that described above.

Exchange considers the pound sterling as a value determined according to the combination of the values of all the different currencies, in proportion as payments are made in the one or the other; and as debtors generally take care to pay in the worst species they can, it consequently follows, that the value of the pound sterling should fall to that of the lowest currency.

Were there a sufficient quantity of worn gold and silver to acquit all bills of exchange, the pound sterling would come down to the value of them; but if the new gold be also necessary for that purpose, the value of it must be proportionally greater.

All these combinations are liquidated and compensated with one another, by the operations of trade and exchange: and the pound sterling, which is so different in itself, becomes thereby, in the eyes of commerce, a determinate unit, subject however to variations, from which it never can be exempted.

Exchange, therefore, is one of the best measures for valuing a pound sterling, present currency. Here occurs a question:

Does the great quantity of paper money in England tend to diminish the value of the pound sterling?

We answer in the negative. *Paper money* is just as good as gold or silver money, and no better. The variation of the standard, we have already laid, must influence the interests of debtors and creditors proportionally every where. From this it follows, that all augmentation of the value of the money unit in the specie must hurt the debtors in the paper money; and all diminutions, on the other hand, must hurt the creditors in the paper money as well as every where else. The payments, therefore, made in paper money, never can contribute to the regulation of the standard of the pound sterling; it is the specie received in liquidation of that paper money which alone can contribute to mark the value of the British unit; because it is affixed to nothing else.

From this we may draw a principle, "That in countries where the money unit is entirely affixed to the coin, the actual value of it is not according to the legal standard of that coin, but according to the mean proportion of the actual worth of those currencies in which debts are paid.

From this we see the reason why the exchange between England and all other trading towns in Europe has long appeared so unfavourable. People calculate the real par, upon the supposition that a pound sterling is worth 1718.7 grains troy of fine silver, when in fact the currency is not perhaps worth 1638, the value of a new guinea in silver, at the market proportion of 1 to 14.5; that is to say, the currency is but 95.3 per cent of the silver standard of the 43d of Elizabeth. No wonder then if the exchange be thought unfavourable.

From the principle we have just laid down, we may gather a confirmation of what we advanced concerning the cause of the advanced price of bullion in the English market.

When people buy bullion with current money at a determinate price, that operation, in conjunction with the course of exchange, ought naturally to mark the actual value of the pound sterling with great exactness.

If therefore the price of standard bullion in the English market, when no demand is found for the exportation of the metals, that is to say, when paper is found for paper upon exchange, and when merchants versed in these matters judge exchange (that is, remittances) to be at par, if then, silver bullion cannot be bought at a lower price than 65 pence the ounce, it is evident that this bullion might be bought with 65 pence in shillings, of which 65 might be coined out of the pound troy English standard silver; since 65 per ounce implies 65 shillings for the 12 ounces or pound troy.

This plainly shews how standard silver bullion should sell for 65 pence the ounce, in a country where the ounce of standard silver in the coin is worth no more than 62; and were the market price of bullion to stand uniformly at 65 pence *per ounce*, that would shew the value of the pound sterling to be tolerably fixed. All the heavy silver coin is now carried off; because it was intrinsically worth more than the gold it passed for in currency. The silver therefore which remains is worn down to the market proportion of the metals, as has been said; that is to say, 20 shillings in silver currency are worth 113 grains of fine gold, at the proportion of 1 to 14.5 between gold and silver. Now,

as 1 is to 14.5, so is 113 to 1638.
so the 20 shillings current weigh but 1638 grains fine silver, instead of 1718.7, which they ought to do according to the standard.

Now let us speak of standard silver, since we are examining how far the English coin must be worn by use.

The pound troy contains 5760 grains. This, according to the standard, is coined into 62 shillings; consequently, every shilling ought to weigh 92.9 grains. Of such shillings it is impossible that ever standard bullion should sell at above 62 pence *per ounce*. If therefore such bullion sells for 65 pence, the shillings with which it is bought must weigh to more than 88.64 grains standard silver; that is, they must lose 4.29 grains, and are reduced to $\frac{1}{87}$ of a pound troy.

But it is not necessary that bullion be bought with shillings; no stipulation of *price* is ever made farther, than at so many pence sterling *per ounce*. Does not this virtually determine the value of such currency with re-

gard to all the currencies in Europe? Did a Spaniard, a Frenchman, or a Dutchman, know the exact quantity of silver bullion which can be bought in the London market for a pound sterling, would he inform himself any farther as to the intrinsic value of that money-unit; would he not understand the value of it far better from that circumstance than by the course of any exchange, since exchange does not mark the intrinsic value of money, but only the value of that money transported from one place to another?

The price of bullion, therefore, when it is not influenced by extraordinary demand, (such as for the payment of a balance of trade, or for making an extraordinary provision of plate) but when it stands at what every body knows to be meant by the common market price, is a very tolerable measure of the value of the *actual* money standard in any country.

If it be therefore true, that a pound sterling cannot purchase above 1638 grains of fine silver bullion, it will require not a little logic to prove that it is really, or has been for these many years, worth any more; notwithstanding that the standard weight of it in England is regulated by the laws of the kingdom at 1718.7 grains of fine silver.

If to this valuation of the pound sterling drawn from the price of bullion, we add the other drawn from the course of exchange; and if by this we find, that when paper is found for paper upon exchange, a pound sterling cannot purchase above 1638 grains of fine silver in any country in Europe; upon these two authorities we may very safely conclude (as to the matter of fact at least) that the pound sterling is not worth more, either in London or in any other trading city; and if this be the case, it is just worth 20 shillings of 65 to the pound troy.

If therefore the mint were to coin shillings at that rate, and pay for silver bullion at the market price, that is, at the rate of 65 pence *per* ounce in those new coined shillings, they would be in proportion to the gold; silver would be carried to the mint equally with gold; and would be as little subject to be exported or melted down.

It may be inquired in this place, how far the coining the pound troy into 65 shillings is contrary to the laws of England?

The moment a state pronounces a certain quantity of gold to be worth a certain quantity of silver, and orders these respective quantities of each metal to be received as equivalents of each other, and as lawful money in payments, that moment gold is made a standard as much as silver. If therefore too small a quantity of gold be ordered or permitted to be considered as an equivalent for the unit, the silver standard is from that moment debased; or indeed, more properly speaking, all silver money is from that moment proscribed; for who, from that time, will ever pay in silver, when he can pay cheaper in gold? Gold, therefore, by such a law, is made the standard, and all declarations to the contrary are against the matter of fact.

Were the king, therefore, to coin silver at 65 shillings in the pound, it is demonstration, *that by such an act* he would commit no adulteration upon the standard: the adulteration is already committed. The standard has

descended to where it is, by slow degrees, and by the operation of political causes only; and nothing prevents it from falling lower, but the standard of the gold coin. Let guineas be now left to seek their value as they did formerly, and let light silver continue to go by tale, we shall see the guineas up at 30 shillings in 20 years time, as was the case in 1695.

It is as absurd to say that the standard of Queen Elizabeth has not been debased by enacting that the English unit shall be acquitted with 113 grains of fine gold, as it would be to affirm that it would not be debased from what it is at present by enacting that a pound of butter should every where be received in payment for a pound sterling; although the pound sterling should continue to consist of 3 ounces, 17 penny-weights, and 10 grains of standard silver, according to the statute of the 43d of Elizabeth. In that case most debtors would pay in butter, and silver would, as at present, acquire a conventional value as a metal, but would be looked upon no longer as a standard, or as money.

If therefore, by the law of England, a pound sterling must consist of 1718.7 grains troy of fine silver; by the law of England also, 113 grains of gold must be of the same value: but no law can establish that proportion; consequently, in which ever way a reformation be brought about, some law must be reversed; consequently, expediency, and not compliance with law, must be the motive in reforming the abuse.

From what has been said, it is not at all surprising that the pound sterling should in fact be reduced nearly to the value of the gold. Whether it ought to be kept at that value is another question. All that we here decide, is, that coining the pound troy into 65 shillings would restore the proportion of the metals, and render both species common in circulation. But restoring the weight and proportion of the coin is not the difficulty which prevents a reformation of the English coinage.

Circumstances to be attended to in a new regulation of the British coin.

To people who do not understand the nature of such operations, it may have an air of justice to support the unit at what is commonly believed to be the standard of Queen Elizabeth, to wit, at 1718.5 grains of fine silver.

The regulating the standard of both silver and gold to $\frac{1}{2}$ fine, and the pound sterling to four ounces standard silver, as it stood during the reign of Queen Mary I. has also its advantages, as Mr Harris has observed. It makes the crown piece to weigh just one ounce, the shilling four penny weight, and the penny eight grains; consequently, were the new statute to bear, that the weight of the coin should regulate its currency upon certain occasions, the having the pieces adjusted to certain aliquot parts of weight would make weighing easy, and would accustom the common people to judge of the value of money by its weight, and not by the stamp.

In that case, there might be a conveniency in striking the gold coins of the same weight with the silver; because the proportion of their values would then constantly be the same with the proportion of the metals. The gold crowns would be worth at present, 3*l.* 12*s.* 6*d.* the

half

half crowns 1*l.* 16*s.* 3*d.* the gold shillings 1*l.* 4*s.* and 6*d.* and the half 7*s.* and 3*d.* This was anciently the practice in the Spanish mints.

The interests within the state can be nowise perfectly protected but by permitting conversions of value from the old to the new standard, whatever it be, and by regulating the footing of such conversions by act of parliament, according to circumstances.

For this purpose, we shall examine those interests which will chiefly merit the attention of government, when they form a regulation for the future of acquitting permanent contracts already entered into. Such as may be contracted afterwards will naturally follow the new standard.

The landed interest is, no doubt, the most considerable in the nation. Let us therefore examine, in the first place, what regulations it may be proper to make, in order to do justice to this great class, with respect to the land-tax on one hand, and with respect to their lessees on the other.

The valuation of the lands of England was made many years ago, and reasonably ought to be supported at the real value of the pound sterling at that time, according to the principles already laid down. The general valuation, therefore, of the whole kingdom will rise according to this scheme. This will be considered as an injustice; and no doubt it would be so, if, for the future, the land tax be imposed as heretofore, without attending to this circumstance; but as that imposition is annual, as it is laid on by the landed interest itself, who compose the parliament, it is to be supposed that this great class will at least take care of their own interest.

Were the valuation of the lands to be stated according to the valuation of the pound sterling of 1718.7 grains of silver, which is commonly supposed to be the standard of Elizabeth, there would be no great injury done; this would raise the valuation only 5 *per cent.* and the land tax in proportion.

There is no class of inhabitants in all England so much at their ease, and so free from taxes, as the class of farmers. By living in the country, and by consuming the fruits of the earth without their suffering any alienation, they avoid the effect of many excises, which, by those who live in corporations, are felt upon many articles of their consumption, as well as on those which are immediately loaded with these impositions. For this reason it will not, perhaps, appear unreasonable, if the additional 5 *per cent.* on the land tax were thrown upon this class, and not upon the landlords.

With respect to leases, it may be observed, that we have gone upon the supposition that the pound sterling in the year 1728, was worth 1718.7 grains of fine silver, and 113 grains of fine gold.

There would be no injustice done the lessees of all the lands in the kingdom, were their rents to be fixed at the mean proportion of these values. We have observed how the pound sterling has been gradually diminishing in its worth from that time by the gradual rise of the silver. This mean proportion, therefore, will nearly answer to what the value of the pound sterling was in 1743; supposing the rise of the silver to have been uniform.

It may be farther alledged in favour of the landlords,

that the gradual debasement of the standard has been more prejudicial to their interest in letting their lands, than to the farmers in disposing of the fruits of them. Proprietors cannot so easily raise their rents upon new leases, as farmers can raise the prices of their grain, according to the debasement of the value of the currency.

The pound sterling, thus regulated at the mean proportion of its worth, as it stands at present, and as it stood in 1728, may be realized in 1678.6 grains of fine silver, and 115.76 grains fine gold; which is 2.4 *per cent.* above the value of the present currency. No injury, therefore, would be done to lessees, and no unreasonable gain would accrue to the landed interest, in appointing conversions of all land rents at 2½ *per cent.* above the value of the present currency.

Without a thorough knowledge of every circumstance relating to Great Britain, it is impossible to lay down any plan. It is sufficient, here, briefly to point out the principles upon which it must be regulated.

The next interest to be considered is that of the nation's creditors. The right regulation of their concerns will have a considerable influence in establishing public credit upon a solid basis, by making it appear to all the world, that no political operation upon the money of Great Britain can in any respect either benefit or prejudice the interest of those who lend their money upon the faith of the nation. The regulating also the interest of so great a body, will serve as a rule for all creditors who are in the same circumstances, and will, upon other accounts, be productive of greater advantages to the nation in time coming.

In 1749, a new regulation was made with the public creditors, when the interest of the whole redeemable national debt was reduced to 3 *per cent.* This circumstance infinitely facilitates the matter, with respect to this class, since, by this innovation of all former contracts, the whole national debt may be considered as contracted at or posterior to the 25th of December 1749.

Were the state, by any arbitrary operation upon money, (which every reformation must be,) to diminish the value of the pound sterling in which the parliament at that time bound the nation to acquit those capitals and the interest upon them, would not all Europe say, that the British parliament had defrauded their creditors? If therefore the operation proposed to be performed should have a contrary tendency, to wit, to augment the value of the pound sterling with which the parliament at that time bound the nation to acquit those capitals and interests, must not all Europe also agree, that the British parliament had defrauded the nation?

This convention with the ancient creditors of the state, who, in consequence of the debasement of the standard, might have justly claimed an indemnification for the loss upon their capitals, lent at a time when the pound sterling was at the value of the heavy silver, removes all cause of complaint from that quarter. There was in the year 1749, an innovation in all their contracts; and they are now to be considered as creditors only from the 25th of December of that year.

Let the value of the pound sterling be inquired into, during one year preceding and one posterior to the trans-

action.

action of the month of December 1749. The great sums borrowed and paid back by the nation during that period will furnish data sufficient for that calculation. Let this value of the pound be specified in troy grains of fine silver and fine gold bullion, without mentioning any denomination of money according to the exact proportion of the metals at that time. And let this pound be called the *pound of national credit*.

This first operation being determined, let it be enacted, that the pound sterling, by which the state is to borrow for the future, and that in which the creditors are to be paid, shall be the exact mean proportion between the quantities of gold and silver above specified, according to the actual proportion of the metals at the time such payments shall be made; or that the sums shall be borrowed or acquitted, one half in gold and one half in silver, at the respective requisitions of the creditors or of the state, when borrowing. All debts contracted posterior to 1749, may be made liable to conversions.

The consequence of this regulation will be the insensible establishment of a bank money. Nothing would be more difficult to establish, by a positive revolution, than such an invariable measure; and nothing will be found so easy as to let it establish itself by its own advantages. This bank money will be liable to much fewer inconveniences than that of Amsterdam. There the persons transacting must be upon the spot; here, the sterling currency may, every quarter of a year, be adjusted by the exchequer to this invariable standard, for the benefit of all debtors and creditors, who incline to profit of the stability of this measure of value.

This scheme is liable to no inconvenience from the variation of the metals, let them be ever so frequent, or hard to be determined; because upon every occasion where there is the smallest doubt as to the actual proportion, the option competent to creditors to be paid half in silver and half in gold will remove.

Such a regulation will also have this good effect, that it will give the nation more just ideas of the nature of money, and consequently of the influence it ought to have upon prices.

If the value of the pound sterling shall be found to have been by accident less in December 1749, than it is at present; or if at present the currency be found below what has commonly been since 1749, in justice to the creditors, and to prevent all complaints, the nation may grant them the mean proportion of the value of the pound sterling from 1749 to 1760; or any other which may to parliament appear reasonable.

This regulation must appear equitable in the eyes of all Europe; and the strongest proof of it will be, that it will not produce the smallest effect prejudicial to the interest of the foreign creditors. The course of exchange with regard to them will stand precisely as before.

A Dutch, French, or German creditor, will receive the same value for his interest in the English stocks as heretofore. This must silence all clamours at home, being the most convincing proof, that the new regulation of the coin will have made no alteration upon the real value of any man's property, let him be debtor or creditor.

The interest of every other denomination of creditors, whose contracts are of a fresh date, may be regulated upon the same principles. But where debts are of an old standing, justice demands, that attention be had to the value of money at the time of contracting. Nothing but the stability of the English coin, when compared with that of other nations, can make such a proposal appear extraordinary. Nothing is better known in France than this stipulation added to obligations, *Argent au cours de ce jour*: that is to say, that the sum shall be repaid in coin of the same intrinsic value with what has been lent. Why should such a clause be thought reasonable for guarding people against arbitrary operations upon the numery value of the coin, and not be found just upon every occasion when the numery value of it is found to be changed, let the cause be what it will?

The next interest we shall examine is that of trade. When men have attained the age of twenty one, they have no more occasion for guardians. This may be applied to traders: they can party with their pen every inconvenience which may result to other people from the changes upon money, provided only the laws permit them to do themselves justice with respect to their engagements. This class demands no more than a right to convert all reciprocal obligations into denominations of coin of the same intrinsic value with those they have contracted in.

The next interest is that of buyers and sellers; that is, of manufacturers with regard to consumers, and of servants with respect to those who hire their personal service.

The interest of this class requires a most particular attention. They must, literally speaking, be put to school, and taught the first principles of their trade, which is buying and selling. They must learn to judge of price by the grains of silver and gold they receive: They are children of a mercantile mother, however warlike the father's disposition may be. If it be the interest of the state that their bodies be rendered robust and active, it is no less the interest of the state that their minds be instructed in the first principle of the trade they exercise.

For this purpose, tables of conversion from the old standard to the new must be made, and ordered to be put up in every market, in every shop. All duties, all excises, must be converted in the same manner. Uniformity must be made to appear every where. The smallest deviation from this will be a stumbling block to the multitude.

Not only the interest of the individuals of the class we are at present considering, demands the nation's care and attention in this particular; but the prosperity of trade, and the well-being of the nation, are, also deeply interwoven in the execution.

The whole delicacy of the intricate combinations of commerce depends upon a just and equable vibration of prices, according as circumstances demand it. The more therefore the industrious classes are instructed in the principles which influence prices, the more easily will the machine move. A workman then learns to sink his price without regret, and can raise it without avidity. When principles are not understood, prices cannot gently fall, they

they must be pulled down; and merchants dare not suffer them to rise, for fear of abuse, even although the perfection of an infant manufacture should require it.

The last interest is that of the bank of England, which naturally must regulate that of every other.

Had this great company followed the example of other banks, and established a bank money of an invariable standard, as the measure of all their debts and credits, they would not have been liable to any inconvenience upon a variation of the standard.

The bank of England was projected about the year 1694, at a time when the current money of the nation was in the greatest disorder, and government in the greatest distress, both for money and for credit. Commerce was then at a very low ebb; and the only, or at least the most profitable trade of any, was jobbing in coin, and carrying backwards and forwards the precious metals from Holland to England. Merchants profited also greatly from the effects which the utter disorder of the coin produced upon the price of merchandize.

At such a juncture the resolution was taken to make a new coinage; and upon the prospect of this, a company was found, who, for an exclusive charter to hold a bank for 13 years, willingly lent the government upwards of a million sterling at 8 per cent. (in light money we suppose) with a prospect of being repaid both interest and capital in heavy. This was not all: part of the money lent was to be applied for the establishment of the bank; and no less than 4000 pounds a year was allowed to the company, above the full interest, for defraying the charge of management.

Under such circumstances the introduction of bank money was very superfluous, and would have been very impolitic. That invention is calculated against the raising of the standard; but here the bank profited of that rise in its quality of creditor for the money lent, and took care not to commence debtor by circulating their paper, until the effect of the new regulation took place in 1695; that is, after the general recoinage of all the clipped silver.

From that time till now, the bank of England has been the basis of the nation's credit, and with great reason has been constantly under the most intimate protection of every minister.

The value of the pound sterling, as we have seen, has been declining ever since the year 1601, the standard being fixed to silver during all that century, while the gold was constantly rising. No sooner had the proportion taken another turn, and silver begun to rise, than the government of England threw the standard virtually upon the gold, by regulating the value of the guineas at the exact proportion of the market. By these operations, however, the bank has constantly been a gainer (in its quality of debtor) upon all the paper in circulation; and therefore has lost nothing by not having established a bank-money.

The interest of this great company being established upon the principles we have endeavoured to explain, it is very evident, that the government of England never will take any step in the reformation of the coin which in its consequences can prove hurtful to the bank. Such a step

would be contrary both to justice and to common sense. To make a regulation which, by raising the standard, will prove beneficial to the public creditors, to the prejudice of the bank (which we may call the public debtor) would be an operation upon public credit, like that of a person who is at great pains to support his house by props upon all sides, and who at the same time blows up the foundation of it with gun-powder.

We may therefore conclude, that with regard to the bank of England, as well as every other private banker, the notes which are constantly payable upon demand must be made liable to a conversion at the actual value of the pound sterling at the time of the new regulation.

That the bank will gain by this, is very certain; but the circulation of their notes is so swift that it would be absurd to allow to the then possessors of them that indemnification which naturally should be shared by all those through whose hands they have passed, in proportion to the debasement of the standard during the time of their respective possession.

Besides these considerations, which are in common to all states, the government of Great Britain has one peculiar to itself. The interest of the bank, and that of the creditors, are diametrically opposite: every thing which raises the standard, hurts the bank; every thing which can sink it, hurts the creditors: and upon the right management of the one and the other, depends the solidity of public credit. For these reasons, without the most certain prospect of conducting a restitution of the standard to the general advantage as well as appropriation of the nation, no minister will probably ever undertake so dangerous an operation.

We shall now propose an expedient which may remove at least some of the inconveniences which would result from so extensive an undertaking as that of regulating the respective interests in Great Britain by a positive law, upon a change in the value of their money of account.

Suppose then, that, before any change is made in the coin, government should enter into a transaction with the public creditors, and ascertain a permanent value for the pound sterling for the future, specified in a determined proportion of the fine metals in common bullion, without any regard to money of account, or to any coin whatever.

This preliminary step being taken, let the intended alteration of the standard be proclaimed a certain time before it is to commence. Let the nature of the change be clearly explained, and let all such as are engaged in contracts which are dissolvable at will upon the stipulations stipulated, be acquainted between the parties, or innovated as they shall think proper, with certification, that, posterior to a certain day, the stipulations formerly entered into shall be binding according to the denominations of the money of account in the new standard.

As to permanent contracts, which cannot at once be fulfilled and dissolved, such as leases, the parliament may either prescribe the methods and terms of conversion; or a liberty may be given to the parties to annul the contract, upon the debtor's refusing to perform his agreement according to the new standard. Contracts, on the other hand, might remain stable, with respect to credi-

tors who would be satisfied with payments made on the footing of the old standard. If the rise intended should not be very considerable, no great injustice can follow such a regulation.

Annuities are now thoroughly understood, and the value of them is brought to so nice a calculation, that nothing will be easier than to regulate these upon the footing of the value paid for them, or of the subject affected by them. If by the regulation land rents are made to rise in denomination, the annuities charged upon them, ought to rise in proportion; if in intrinsic value, the annuity should remain as it was.

Regulations which the principles of this inquiry point out as expedient to be made by a new statute for regulating the British coin.

LET us now examine what regulations it may be proper to make by a new statute concerning the coin of Great Britain, in order to preserve always the same exact value of the pound sterling realized in gold and in silver, in spite of all the incapacities inherent in the metals to perform the functions of an invariable scale or measure of value.

1. The first point is to determine the exact number of grains of fine gold and fine silver which are to compose it, according to the then proportion of the metals in the London market.

2. To determine the proportion of these metals with the pound troy, and in regard that the standard of gold and silver is different, let the mint price of both metals be regulated according to the pound troy fine.

3. To fix the mint price within certain limits: that is to say, to leave to the King and Council, by proclamation, to carry the mint price of bullion up to the value of the coin, as is the present regulation, or to sink it to *per cent.* below that price, according as government shall incline to impose a duty upon coinage.

4. To order, that silver and gold coin shall be struck of such denominations as the King shall think fit to appoint; in which the proportion of the metals above determined shall be constantly observed through every denomination of the coin, until necessity shall make a new general coinage unavoidable.

5. To have the number of grains of the fine metal in every piece marked upon the exergue, or upon the legend of the coin, in place of some initial letters of titles, which not one person in a thousand can decipher; and to make the coin of as compact a form as possible, diminishing the surface of it as much as is consistent with beauty.

6 That it shall be lawful for all contracting parties to stipulate their payments either in gold or silver coin, or to leave the option of the species to one of the parties.

7. That where no particular stipulation is made, creditors shall have power to demand payment, half in one species, half in the other; and when the sum cannot fall equally into gold and silver coins, the fractions to be paid in silver.

8. That in buying and selling, when no particular species has been stipulated, and when no act in writing has

intervened, the option of the species shall be competent to the buyer.

9. That all sums paid or received by the King's receivers, or by bankers, shall be delivered by weight, if demanded.

10 That all money which shall be found under the legal weight, from whatever cause it may proceed, may be rejected in every payment whatsoever; or if offered in payment of a debt above a certain sum, may be taken according to its weight, at the then mint price, in the option of the creditor.

11. That no penalty shall be incurred by those who melt down or export the nation's coin; but that washing, clipping, or diminishing the weight of any part of it shall be deemed felony, as much as any other theft, if the person so degrading the coin shall afterwards make it circulate for lawful money.

To prevent the inconveniences proceeding from the variation in the proportion between the metals, it may be provided,

12. That upon every variation of proportion in the market price of the metals, the price of both shall be changed, according to the following rule.

Let the price of the pound troy fine gold in the coin be called G.

Let the price of ditto in the silver be called S.

Let the new proportion between the market price of the metals be called P.

Then state this formula:

$\frac{G}{2P} + \frac{S}{2} =$ to a pound troy fine silver, in sterling currency.

$\frac{S}{2} + P + \frac{G}{2} =$ to a pound troy fine gold, in sterling currency.

This will be a rule for the mint, to keep the price of the metals constantly at par with the price of the market; and coinage may be imposed, as has been described, by fixing the mint price of them at a certain rate below the value of the fine metals in the coin.

13. As long as the variation of the market price of the metals shall not carry the price of the rising metal so high as the advanced price of the coin above the bullion, no alteration need be made on the denomination of either species.

14. So soon as the variation of the market price of the metals shall give a value to the rising species, above the difference between the coin and the bullion; then the king shall alter the denominations of all the coin, silver and gold, adding to the coins of the rising metal exactly what is taken from those of the other. An example will make this plain.

Let us suppose that the coinage has been made according to the proportion of 14 5 to 1; that 20 shillings, or 4 crown pieces, shall contain, in fine silver, 14.5 times as many grains as the guinea, or the gold pound, shall contain grains of fine gold. Let the new proportion of the metals be supposed to be 14 to 1. In that case, the 20 shillings, or the 4 crowns, will contain $\frac{5}{14}$ more value than the guinea. Now since there is no question of making a new general coinage upon every variation, in order to adjust the proportion of the metals in the weight of

of the coins, that proportion must be adjusted by changing their respective denominations according to this formula.

Let the 20 shillings, or 4 crowns, in coin, be called S. Let the guinea be called G. Let the difference between the old proportion and the new, which is $\frac{1}{8}$, be called P. Then say,

$$S - \frac{P}{2} = \text{a pound sterling, and } G + \frac{P}{2} = \text{a pound sterling.}$$

By this it appears that all the silver coin must be raised in its denomination $\frac{1}{8}$, and all the gold coin must be lowered in its denomination $\frac{1}{8}$; yet still S+G will be equal to two pounds sterling, as before, whether they be considered according to the old, or according to the new denominations.

But it may be observed, that the imposition of coinage rendering the value of the coin greater than the value of the bullion, that circumstance gives a certain latitude in fixing the new denominations of the coin, so as to avoid minute fractions. For, providing the deviation from the exact proportion shall fall within the advanced price of the coin, no advantage can be taken by melting down one species preferably to another; since, in either case, the loss incurred by melting the coin must be greater than the profit made upon selling the bullion. The mint price of the metals, however, may be fixed exactly, that is, within the value of a farthing upon a pound of fine silver or gold. This is easily reckoned at the mint; although upon every piece in common circulation the fractions of farthings would be inconvenient.

15. That notwithstanding of the temporary variations made upon the denomination of the gold and silver coins, all contracts formally entered into, and all stipulations in pounds shillings and pence, may continue to be acquitted according to the old denominations of the coins, paying one half in gold, and one half in silver: unless in the case where a particular species has been stipulated; in which case, the sums must be paid according to the new regulation made upon the denomination of that species to the end that neither profit or loss may result to any of the parties.

16. That notwithstanding the alterations on the mint price of the metals, and in the denomination of the coins, no change shall be made upon the weight of the particular pieces of the latter, except in the case of a general recoinage of one denomination at least: that is to say, the mint must not coin new guineas, crowns, &c. of a different weight from those already in currency, although by so doing the fractions might be avoided. This would occasion confusion, and the remedy would cease to be of any use upon a new change in the proportion of the metals. But it may be found convenient, for removing the

small fractions in shillings and sixpences, to recoin such denominations all together, and to put them to their integer numbers, of twelve and of six pence, without changing in any respect their proportion of value to all other denominations of the coin: this will be no great expence, when the bulk of the silver coin is put into 5 shilling pieces.

By this method of changing the denominations of the coin, there never can result any alteration in the value of the pound sterling; and although fractions of value may now and then be introduced, in order to prevent the abuses to which the coin would otherwise be exposed by the artifice of those who melt it down, yet still the inconvenience of such fractions may be avoided in paying, according to the old denominations, in both species, by equal parts. This will also prove demonstratively, that no change is thereby made in the true value of the national unit of money.

17. That it be ordered, that shillings and sixpences shall only be current for twenty years, and all other coins, both gold and silver, for forty years, or more. For ascertaining which term, there may be marked, upon the exergue of the coin, the last year of their currency, in place of the date of their fabrication. This term elapsed, or the date effaced, that they shall have no more currency whatsoever; and when offered in payment, may be received as bullion at the actual price of the mint, or refused at the option of the creditor.

18. That no foreign coin shall have any legal currency, except as bullion at the mint price.

By these or the like regulations may be prevented, 1^{mo}, The melting or exporting of the coin in general. 2^{do}, The melting or exporting one species, in order to sell it as bullion, at an advanced price. 3^{tho}, The profit in acquitting obligations preferably in one species to another. 4^{to}, The degradation of the standard, by the wearing of the coin, or by a change in the proportion between the metals. 5^{to}, The circulation of the coin below the legal weight. 6^{to}, The profit that other nations reap by paying their debts more cheaply to Great Britain than Great Britain can pay hers to them.

And the great advantage of it is, that it is an uniform plan, and may serve as a perpetual regulation, compatible with all kinds of denominations of coins, variations in the proportion of the metals, and with the imposition of a duty upon coinage; or with the preserving it free; and further, that it may in time be adopted by other nations, who will find the advantage of having their money of account preserved perpetually at the same value, with respect to the denominations of all foreign money of account established on the same principles.

A T A B L E O F C O I N S , Shewing the Quantity of Fine Metal contained in them.

The number of grains of fine metal in every coin is sought for in the regulations of the mint of the country where it is coined, and is expressed in the grains in use in that mint. From that weight it is converted into thole of other countries, according to the following proportions :

3840 Troy grains, 476.35 Paris grains, 5192.8 Holland aces or grains, and 4619.06 Colonia grains, are supposed to be equal weights ; and the coins in the Table are converted according to thole proportions.

MONK, a person who wholly dedicates himself to the service of religion, in some monastery, under the direction of some particular statutes and rules.

The most probable account of the original of the monks is, that in the Decian persecution, in the middle of the III^d century, many persons in Egypt, to avoid the fury of the storm, fled to the neighbouring deserts and mountains, where they not only found a safe retreat, but also more time and liberty to exercise themselves in acts of piety and divine contemplations; which sort of life became so agreeable, that when the persecution was over, they refused to return to their habitations again, chusing rather to continue in those cottages and cells, which they had made for themselves in the wildernesses. From that time to the reign of Constantine, monachism was confined to the hermits or anachorets, who lived in private cells in the wildernesses; but when Pachomius had erected monasteries, other countries presently followed the example.

MONKEY, in zoology. See **SIMIA**.

MONMOUTH, the capital of Monmouth-shire, situated on the river Wye, twenty-five miles north of Bristol.

MONOCHORD, a musical instrument, composed of one string, used to try the variety and proportion of sounds.

MONOCULUS, in zoology, a genus of the order of aptera. The feet are fitted for swimming; the body is covered with a crustaceous skin; and the eyes are very near each other. There are nine species.

MONODON, in ichthyology, a genus of fishes belonging to the order of bete. It has a long wreathed tooth in the upper jaw, which perforates the upper-lip, and has the appearance of a horn; from this circumstance it has got the name of the unicorn-fish. This fish is of the whale kind, and often grows to 25 feet in length, though the general size is from 16 to 20.

MONODY, in ancient poetry, a mournful kind of song, sung by a person all alone, to give vent to his grief.

MONOECIA, in botany. See **BOTANY**, p. 635.

MONOGAMY, the state or condition of those who have only been once married, and are restrained to a single wife.

MONOGRAM, a character or cypher, composed of one, two, or more letters, interwoven; being a kind of abbreviation of a name, anciently used as a seal, badge, arms, &c.

MONOLOGUE, in poetry, a dramatic scene, in which a person appears alone on the stage, and speaks to himself.

MONOMOTOPA, a country of Africa, bounded by Monemupi on the north, and by Cafraria on the east, south, and west.

MONOPETALOUS, in botany, a term applied to flowers that have only one petal, or flower-leaf.

MONOPOLI, a town in the kingdom of Naples, situated on the gulph of Venice: E. long. 18°, and N. lat. 41° 5'.

MONOPOLY, one or more persons making themselves the sole masters of the whole of a commodity, manufacture, and the like, in order to make private ad-

vantage of it, by selling it again at a very advanced price.

MONOPYRENEOUS, in botany, such fruit as contains only one seed, or kernel.

MONOSTICH, an epigram that consists of only one single verse.

MONOSYLLABLE, in grammar, a word that consists of only one syllable, and is composed of either one or more letters pronounced at the same time.

MONOTONY, an uniformity of sound, or a fault in pronunciation, when a long series of words are delivered in one unvaried tone.

MONOTROPA, in botany, a genus of the decandria monogynia class. It has no calix; the petals are ten; and it has five capsules. There are two species, one of which, *viz.* the hypophysis, or bird's nest smelling like the roots of the primrose, is a native of Britain.

MONS, the capital of the province of Hainalt, in the Austrian Netherlands: situated twenty-six miles south-west of Brussels: east long. 3° 33', and south lat. 51° 34'.

MONSIEUR, a title of civility used by the French, in speaking to, or of their equals, or those that are but a little below them, synonymous with **SIR** in English.

MONSOON, in physiology, a species of trade wind, in the East-Indies, which for six months blows constantly the same way, and the contrary way the other six months. See **PNEUMATICS**, *Of Winds*.

MONSTER, in general, denotes any production that deviates from the species to which it belongs, whether with respect to the number or disposition of its parts; in which sense, a man with six fingers on each hand, or six toes on each foot, is a monster. But the term monster seems to be chiefly applied to such productions as deviate very much from the ordinary course of nature.

MONTE SANCTO, or **MOUNT-ATHOS**, a mountain of European Turkey, in the province of Macedon: E. long. 23°, and N. lat. 40° 12'.

It is called *Monte Sancto*, or *Holy Mountain*, from twenty two monasteries situated upon it, in which are four thousand monks or friars, who never suffer a woman to come within sight of their convent.

MONTFERRAT, a duchy in Italy, bounded by the lordship of Verceil on the north, by the Alexandrin on the east, by the territory of Genoa on the south, and by the county of Asti on the west.

MONTFORT, the capital of the county of Montfort, in the circle of Swabia, in Germany: E. long. 9° 40', and N. lat. 47° 15'.

MONTGOMERY, the capital of Montgomeryshire, in Wales, situated on the river Severn, twenty miles south-west of Shrewsbury.

MONTH, the twelfth part of a year. See **ASTRONOMY**.

MONTIA, in botany, a genus of the triandria trigynia class. The calix consists of one leaf, and the corolla of one irregular petal; and the capsule has one cell and three valves. There is but one species, *viz.* the sentana, or water chickweed, a native of Britain.

MONTIFRINGILLA,

MONTFRINGILLA, in zoology. See FRINGILLA.

MONTPELIER, a city of France, in the province of Languedoc and county of Nîmes, situated on the little river Lez, fifty miles north-east of Narbonne, and forty five miles south-west of Avignon; a place famous for its delightful situation, and its healthy serene air.

MONTREAL, a city of Sicily, in the province of Mazarra, situated near the sea, five miles east of Palermo.

MONTREAL is also a town of Canada, in North America, situated on the river of St Laurence, one hundred miles south of Quebec.

MONTROSE, a town of North Britain, in the shire of Angus, situated at the mouth of the river Esk, on the German ocean, forty-six miles north-east of Edinburgh.

Steel spaws are very numerous in the country about Montrose; besides these, there is a well near this town whose water is of a whitish colour, soft taste, and faintly discovering a mineral quality, and is of a different nature from the steel one. It is universally diuretic; and has been found useful in stranguries, stoppages of urine, scorbutic disorders, flatulencies, &c.

MONTSERAT, a mountain of Spain, in the province of Catalonia, twenty-one miles north-west of Barcelona,

where there is a monastery and chapel dedicated to the Virgin Mary, to which there is a great resort of pilgrims.

MONTSERAT is also one of the smallest of the Caribbee islands; it is situated about thirty miles south-west of Antigua.

MONUMENT, in architecture, a building destined to preserve the memory, &c. of the person who raised it, or for whom it was raised; such are a triumphal arch, a mausoleum, a pyramid, &c.

MOOD, or MODE. See LOGIC and METAPHYSICS. Moon, or MODE, in grammar, the different manner of conjugating verbs. See GRAMMAR.

MOON, in astronomy. See ASTRONOMY, p. 440.

MOON-WORT, in botany. See LUNARIA.

MOOR, in country affairs, denotes an unlimited tract of land, usually over-run with heath.

MOOR-BUZZARD. See FALCO.

MOOR-CKOCK, or GOR-CKOCK. See TETRAO.

MOOR-STONE, a valuable stone, much used in the coarser works of the present builders; being truly a white granite, of a marbly texture.

MOORING, or MOAKING, in the sea language, is the laying out the anchors of a ship in a place where she can ride secure.

MORAL, something belonging to manners, or the conduct of life. See—

MORAL PHILOSOPHY, OR MORALS.

MORAL PHILOSOPHY is “The science of MAN-
“NERS or DUTY; which it traces from man’s
“nature and condition, and shews to terminate in his hap-
“piness.” In other words, it is “The knowledge of
“our DUTY and FELICITY;” or, “The art of being
“VIRTUOUS and HAPPY.”

It is denominat^d an art, as it contains a system of rules for becoming virtuous and happy. Whoever practises these rules, attains an habitual power or facility of becoming virtuous and happy. It is likewise called a science, as it deduces those rules from the principles and connexions of our nature, and proves that the observance of them is productive of our happiness.

It is an art, and a science, of the highest dignity, importance, and use. Its object is man’s duty, or his conduct in the several moral capacities and connexions which he sustains. Its office is to direct that conduct; to shew whence our obligations arise, and where they terminate. Its use, or end, is the attainment of happiness; and the means it employs are rules for the right conduct of our moral powers.

Moral Philosophy has this in common with Natural Philosophy, that it appeals to nature or fact; depends on observation; and builds its reasonings on plain uncontroverted experiments, or upon the fullest induction of particulars of which the subject will admit. We must observe, in both these sciences, how nature is affected, and what her conduct is in such and such circumstances. Or,

in other words, we must collect the appearances of nature in any given instance; trace these to some general principles, or laws of operation; and then apply these principles or laws to the explaining of other phenomena.

Therefore Moral Philosophy inquires, not how man might have been, but how he is, constituted; not into what principles or dispositions his actions may be artfully resolved; but from what principles and dispositions they actually flow: not what he may, by education, habit, or foreign influence, come to be, or do; but what, by his nature, or original constituent principles, he is formed to be and do. We discover the office, use, or destination of any work, whether natural or artificial, by observing its structure, the parts of which it consists, their connection or joint action. It is thus we understand the office and use of a watch, a plant, an eye, or hand. It is the same with a living creature, of the rational, or brute kind. Therefore, to determine the office, duty, or destination of man; or, in other words, what his business is, or what conduct he is obliged to pursue; we must inspect his constitution, take every part to pieces, examine their mutual relations one to the other, and the common effort or tendency of the whole.

Of Man and his connections.

MAN is born a weak, helpless, delicate creature; unprovided with food, cloathing, and whatever else is necessary for subsistence, or defence. And yet, exposed as the

the infant is to numberless wants and dangers, he is utterly incapable of supplying the former, or securing himself against the latter. But, though thus feeble and exposed, he finds immediate and sure resources in the affection and care of his parents, who refuse no labours, and forego no dangers, to nurse and rear up the tender babe. By these powerful instincts, as by some mighty chain, does nature link the parent to the child, and form the strongest moral connection on his part, before the child has the least apprehension of it. Hunger and thirst, with all the sensations that accompany or are connected with them, explain themselves by a language strongly expressive, and irresistibly moving. As the several senses bring in notices and informations of surrounding objects, we may perceive in the young spectator early signs of a growing wonder and admiration. Bright objects and striking sounds are beheld and heard with a sort of commotion and surprise. But without resting on any, he eagerly passes on from object to object, still pleased with whatever is most new. Thus the love of novelty is formed, and the passion of wonder kept awake. By degrees he comes acquainted with the most familiar objects, his parents, his brethren, and those of the family who are most conversant with him. He contracts a fondness for them; is uneasy when they are gone, and charmed to see them again. These feelings become the foundation of a moral attachment on his side; and by this reciprocal sympathy he forms the domestic alliance with his parents, brethren, and other members of the family. Hence he becomes interested in their concerns; and feels joy or grief, hope or fear, on their account, as well as his own. As his affections now point beyond himself to others, he is denominated a good or ill creature, as he stands well or ill affected to them. These then are the first links of the moral chain, the early rudiments or outlines of his character, his first rude essays towards agency, freedom, manhood.

When he begins to make excursions from the nursery, and extend his acquaintance abroad, he forms a little circle of companions, engages with them in play or in quest of adventures, and leads or is led by them as his genius is more or less aspiring. Though this is properly the season in which appetite and passion have the ascendant, yet his imagination and intellectual powers open apace: and as the various images of things pass before the mental eye, he forms a variety of tastes; relishes some things and dislikes others, as his parents, companions, and a thousand other circumstances, lead him to combine agreeable or disagreeable sets of ideas, or represent to him objects in alluring or odious lights.

As his views are enlarged, his active and social powers expand themselves in proportion; the love of action, of imitation, and of praise, emulation, curiosity, docility, a passion for command, and fondness of change. His passions are quick, variable, and pliant to every impression; his attachments and disgusts quickly forced each other. He compares things, distinguishes actions, judges of characters, and loves or hates them as they appear well or ill affected to himself or to those he holds dear. Mean while, he soon grows sensible of the consequences of his

own actions, as they attract applause, or bring contempt; he triumphs in the former, and is ashamed of the latter, wants to hide them, and blushes when they are discovered. By means of these powers, he becomes a fit subject of culture, the moral tie is drawn closer, he feels that he is accountable for his conduct to others as well as to himself, and thus is gradually ripening for society and action.

As man advances from childhood to youth, his passions as well as perceptions take a more extensive range. New senses of pleasure invite him to new pursuits; he grows sensible to the attractions of beauty, feels a peculiar sympathy with the sex, and forms a more tender kind of attachment than he has yet experienced. This becomes the cement of a new moral relation, and gives a softer turn to his passions and behaviour. In this turbulent period he enters more deeply into a relish of friendship, company, exercises, and diversions; the love of truth, of imitation and of design, grows upon him; and as his connections spread among his neighbours, fellow citizens, and countrymen, his thirst of praise, emulation, and social affections grow more intense and active. Mean while it is impossible for him to have lived thus long without having become sensible of those more august signatures of order, wisdom, and goodness, which are stamped on the visible creation; and of those strong suggestions within himself of a parent mind, the source of all intelligence and beauty, and the object as well as source of that activity and those aspirations which sometimes rouse his inmost frame and carry him out of himself to an all-mighty and all-governing Power: Hence arise those sentiments of reverence, and those affections of gratitude, resignation, and love, which link the soul with the Author of nature, and form that most sublime and godlike of all connections.

Man having now reached his prime, either new passions succeed, or the old set are wound up to an higher pitch. For, growing more sensible of his connection with the public, and that particular community to which he more immediately belongs; and taking withal a larger prospect of human life, and its various wants and enjoyments; he forms more intimate friendships, grasps at power, courts honour, lays down cooler plans of interest, and becomes more attentive to the concerns of society; he enters into family connections, and indulges those charities which arise from thence. The reigning passions of this period powerfully prompt him to provide for the decays of life; and in it compassion and gratitude exert their influence in urging the man, now in full vigour, to requite the affection and care of his parents, by supplying their wants and alleviating their infirmities.

At length human life verges downwards; and old age creeps on apace, with its anxiety, love of ease, interestlessness, fearfulness, foresight, and love of offspring. The experience of the aged is formed to direct, and their coolness to temper, the heat of youth: the former teaches them to look back on past follies; and the latter to look forward into the consequences of things, and provide against the worst. Thus every age has its peculiar genius and set of passions, corresponding to that period, and most conducive to the prosperity of the rest. And thus are the

the wants of one period supplied by the capacities of another, and the weakness of one age tally to the passions of another.

Besides these, there are other passions and affections of a less ambulatory nature; not peculiar to one period, but belonging to every age, and acting more or less in every breath throughout life: such are, self love, benevolence, love of life, honour, shame, hope, fear, desire, aversion, joy, sorrow, anger, and the like. The two first are affections of a cooler train; one pointing to the good of the individual, the other to that of the species: joy, and sorrow, hope and fear, seem to be only modifications, or different exertions of the same original affections of love and hatred, desire and aversion, arising from the different circumstances or position of the object desired or abhorred, as it is present or absent. From these likewise arise other secondary, or occasional passions, which depend, as to their existence and several degrees, upon the original affections being gratified or disappointed; as, anger, complacency, confidence, jealousy, love, hatred, dejection, exultation, contentment, disgust, which do not form leading passions, but rather hold of them.

By these simple, but powerful springs, whether periodical or fixed, the life of man, weak and indigent as he is, is preserved and secured; and the creature is prompted to a constant round of action, even to supply his own numerous and ever-returning wants, and to guard against the various dangers and evils to which he is obnoxious. By these links, men are connected with each other, formed into families, drawn into particular communities, and all united, as by a common league, into one system or body, whose members feel and sympathize one with another. By this admirable adjustment of the constitution of man to his state, and the gradual evolution of his powers, order is maintained, society upheld, and human life filled with that variety of passion and action, which at once enliven and diversify it.

This is a short sketch of the principal movements of the human mind. Yet these movements are not the whole of man: they impel to action, but do not direct it; they need a regulator to guide their motions, to measure and apply their forces. And accordingly they have one that naturally superintends and directs their action. We are conscious of a principle within us, which examines, compares, and weighs things; notes the differences, observes the forces, and forces the consequences of affections and actions. By this power we look back on past times, and forward into futurity, gather experiences, estimate the real and comparative value of objects, lay out schemes, contrive means to execute them, and settle the whole order and economy of life. This power we commonly distinguish by the name of reason, or reflection; the business of which is, not to suggest any original notices or sensations, but to canvass, range, and make deductions from them.

We are intimately conscious of another principle within us, which approves of certain sentiments, passions, and actions, and disapproves of their contraries. In consequence of the decisions of this inward judge, we denominate some actions and principles of conduct *right, honest, good*; and others *wrong, dishonest, ill*. The former ex-

cite our esteem, moral complacency, and affection, immediately and originally of themselves, without regard to their consequences, and whether they affect our interest or not. The latter do as naturally and necessarily call forth our contempt, scorn, and aversion. That power, by which we perceive this difference in affections and actions, and feel a consequent relish or dislike, is commonly called conscience, or the moral sense. Whether such a power belongs to human nature or not, must be referred to every one's experience of what passes within himself.

These two powers of reason and conscience, are evidently principles different in nature and kind from the passions and affections. For the passions are mere force or power, blind impulses, acting violently and without choice, and ultimately tending each to their respective objects, without regard to the interest of the others, or of the whole system: Whereas the directing and judging powers distinguish and ascertain the different forces, mutual proportions, and relations, which the passions bear to each other and to the whole; recognize their several degrees of merit; and judge of the whole temper and conduct, as they respect either the individual or the species; and are capable of directing or restraining the blind impulses of passion in a due consistency one with the other, and a regular subordination to the whole system.

This is some account of the constituent principles of our nature, which, according to their different mixtures, degrees, and proportions, mould our character, and sway our conduct in life. In reviewing that large train of affections which fill up the different stages of human life, we perceive this obvious distinction among them; that some of them respect the good of the individual, and others carry us beyond ourselves to the good of the species, or kind. The former have therefore been called private, and the latter public affections. Of the first sort are love of life, of pleasure, of power, and the like. Of the last are compassion, gratitude, friendship, natural affection, and the like. Of the private passions, some respect merely the security and defence of the creature; such as resentment, and fear: whereas others aim at some positive advantage or good; as wealth, ease, fame. The former sort therefore, because of this difference of objects, may be termed defensive passions. These answer to our dangers, and prompt us to avoid them if we can, or boldly to encounter them when we cannot.

The other class of private passions, which pursue private positive good, may be called appetitive. However, we shall still retain the name of private, in contradistinction to the defensive passions. Man has a great variety of wants to supply, and is capable of many enjoyments, according to the several periods of his life, and the different situations in which he is placed. To these, therefore, a suitable train of private passions correspond, which engage him in the pursuit of whatever is necessary for his subsistence or welfare.

Our public or social affections are adapted to the several social connections and relations which we bear to others, by making us sensible of their dangers, and interdicting us in their wants, and so prompting us to secure them against one, and supply the other.

This is the first step then to discover the duty and destination

slipation of man, the having analyzed the principles of which he is composed. It is necessary, in the next place, to consider in what order, proportion, and measure of those inward principles, virtue, or a sound moral temper and right conduct, consists; that we may discover whence moral obligations arise.

Of Duty, or Moral Obligation.

It is by the end or design of any power or movement, that we must direct its motions, and estimate the degree of force necessary to its just action. If it want the force requisite for the obtaining its end, we reckon it defective; if it has too much, so as to be carried beyond it, we say it is over-charged; and in either case it is imperfect, and ill contrived. If it has just enough to reach the scope, we esteem it right, and as it should be. Let us apply this reasoning to the passions.

The defence and security of the individual being the aim of the defensive passions, that security and defence must be the measure of their strength or indulgence. If they are so weak as to prove insufficient for that end, or if they carry us beyond it, *i. e.* raise unnecessary commotions, or continue longer than is needful, they are unfit to answer their original design, and therefore are in an unbound and unnatural state. The exercise of fear or of resentment has nothing desirable in it, nor can we give way to either without painful sensations. Without a certain degree of them, we are naked and exposed: with too high a proportion of them, we are miserable, and often injurious to others. Thus cowardice or timidity, which is the excess of fear, instead of saving us in danger, gives it too formidable an appearance, makes us incapable of attending to the best means of preservation, and disarms us of courage our natural armour. Fool-hardiness, which is the want of a due measure of fear, leads us heedlessly into danger, and lolls us into a pernicious security. Revenge, *i. e.* excessive resentment, by the violence of its commotion, robs us of that presence of mind which is often the best guard against injury, and inclines us to pursue the aggressor with more severity than self defence requires. Possitanimity, or the want of a just indignation against wrong, leaves us quite unguarded, and tends to sink the mind into a passive enervated tameness. Therefore, "to keep the defensive passions duly proportioned to our dangers, is their natural pitch and tenor."

The private passions lead us to pursue some positive species of private good. That good, therefore, which is the object and end of each, must be the measure of their respective force, and direct their operation. If they are too weak or sluggish to engage us in the pursuit of their several objects, they are evidently deficient; but if they defeat their end by their impetuosity, then are they strained beyond the just tone of nature. Thus vanity, or an excessive passion for applause, betrays into such meanesses and little arts of popularity, as makes us forfeit the honour we so anxiously court. On the other hand, a total indifference about the esteem of mankind, removes a strong guard and spur to virtue, and lays the mind open to the most abandoned profecutions. Therefore, "to keep our private passions and desires proportioned to our

wants, is the just measure and pitch of this class of affections."

The defensive and private passions do all agree in general in their tendency or conduciveness to the interest or good of the individual. Therefore, when there is a collision of interests, as may sometimes happen, that aggregate of good or happiness, which is composed of the particular goods to which they respectively tend, must be the common standard by which their comparative degrees of strength are to be measured. That is to say, if any of them, in the degree in which they prevail, are incompatible with the greatest aggregate of good, or most extensive interest of the individual, then are they unequal and disproportionate. For, in judging of a particular system or constitution of powers, we call that the supreme or principal end, in which the aims of the several parts or powers coincide, and to which they are subordinate; and reckon them in due proportion to each other, and right with regard to the whole, when they maintain that subordination or subserviency. Therefore, "to proportion our defensive and private passions in such measure to our dangers and wants, as best to secure the individual, and obtain the greatest aggregate of private good or happiness, is their just balance or comparative standard in case of competition."

In like manner, as the public or social affections point at the good of others, that good must be the measure of their force. When a particular social affection, as gratitude or friendship, which belongs to a particular social connection, *viz.* that of a benefactor or of a friend, is too feeble to make us act the grateful or friendly part; that affection, being insufficient to answer its end, is defective and unbound. If, on the other hand, a particular passion of this class counteract or defeat the interest it is designed to promote, by its violence or disproportion, then is that passion excessive and irregular. Thus natural affection, if it degenerates into a passionate fondness, not only hinders the parents from judging coolly of the interest of their offspring, but often leads them into a most partial and pernicious indulgence.

As every kind affection points at the good of its particular object, it is possible there may be sometimes a collision of interests or goods. Thus the regard due to a friend may interfere with that which we owe to a community. In such a competition of interests, it is evident, that the greatest is to be chosen; and that is the greatest interest, which contains the greatest sum or aggregate of public good, greatest in quantity as well as duration. This then is the common standard, by which the respective forces and subordinations of the social affections must be adjusted. Therefore we conclude, that this "class of affections are sound and regular, when they prompt us to pursue the interest of individuals in an entire consistency with the public good:" or, in other words, "when they are duly proportioned to the dangers and wants of others, and to the various relations in which we stand to individuals, or to society."

Thus we have found, by an induction of particulars, the natural pitch or tenor of the different orders of affection, considered apart by themselves. Now, as the virtue or perfection of every creature lies in following its nature,

or acting suitably to the just proportion and harmony of its several powers; therefore, "the virtue of a creature endowed with such affections as man, must consist in observing or acting agreeably to their natural pitch and tenor."

But, as there are no independent affections in the fabric of the mind, no passion that stands by itself without some relation to the rest, we cannot pronounce of any one, considered apart, that it is either too strong or too weak. Its strength and just proportion must be measured, not only by its subserviency to its own immediate end, but by the respect it bears to the whole system of affection. Therefore, we say a passion is too strong, not only when it defeats its own end, but when it impairs the force of other passions, which are equally necessary to form a temper of mind suited to a certain œconomy or state; and too weak, not merely on account of its insufficiency to answer its end, but because it cannot sustain its part or office in the balance of the whole system. Thus the love of life may be too strong, when it takes from the regard due to one's country, and will not allow one bravely to encounter dangers, or even death, on its account. Again, the love of fame may be too weak, when it throws down the fences which render virtue more secure, or weakens the incentives which make it more active and public-spirited.

If it be asked, "How far may the affections towards private good or happiness be indulged?" one limit was before fixed for the particular indulgencies of each, *viz.* their subordination to the common aggregate of good to the private system. In these therefore, a due regard is always supposed to be had to health, reputation, fortune, the freedom of action, the unimpaired exercise of reason, the calm enjoyment of one's self, which are all private goods. Another limit now results from the balance of affection just named, *viz.* "The security and happiness of others;" or, to express it more generally, "a private affection may be safely indulged, when, by that indulgence, we do not violate the obligations which result from our higher relations, or public connections." A just respect therefore being had to these boundaries, which nature has fixed in the breast of every man, What should limit our pursuits of private happiness? Is nature sullen and penurious? Or does the God of nature envy the happiness of his offspring?

Whether there is ever a real collision of interests between the public and private system of affections, or the ends which each class has in view, will be afterwards considered; but where there is no collision, there is little or no danger of carrying either, but especially the public affection, to excess, provided both kinds are kept subordinate to a discreet and cool self love, and to a calm and universal benevolence; which principles stand as guards at the head of each system.

This then is the conduct of the passions, considered as particular and separate forces, carrying us out to their respective ends; and this is their balance or œconomy, considered as compound powers, or powers mutually related, acting in conjunction towards a common end, and consequently as forming a system or whole.

Now, whatever adjusts or maintains this balance,

whatever in the human constitution is formed for directing the passions, so as to keep them from defeating their own end or interfering with each other, must be a principle of a superior nature to them, and ought to direct their measures, and govern their proportions. But it was found, that reason or reflection is such a principle, which points out the tendency of our passions, weighs their influence upon private and public happiness, and shews the best means of attaining either. It having been likewise found, that there is another directing or controuling principle, which we call conscience, or the moral sense, which, by a native kind of authority, judges of affections and actions, pronouncing some just and good, and others unjust and ill; it follows, that the passions, which are mere impulses, or blind forces, are principles inferior and subordinate to this judging faculty. Therefore, if we would observe the mutual respects and the subordination which the different parts of the human constitution bear one to another, the passions ought to be subjected to the direction and authority of the leading or controuling principles.

We conclude therefore from this induction, that "the constitution or just œconomy of human nature consists in a regular subordination of the passions and affections to the authority of conscience, and the direction of reason."

That subordination is regular, when the proportion formerly mentioned is maintained; that is to say, "When the defensive passions are kept proportioned to our dangers; when the private passions are proportioned to our wants; and when the public affections are adapted to our public connections, and proportioned to the wants and dangers of others."

But the natural state, or the sound and vigorous constitution, of any creature, or the just œconomy of its powers, we call its health and perfection; and the acting agreeably to these, its virtue or goodness. Therefore, "the health and perfection of man must lie in the aforesaid supremacy of conscience and reason, and in the subordination of the passions to their authority and direction; and his virtue or goodness must consist in acting agreeably to that order or œconomy."

That such an œconomy of the mind, and such a conduct of its power and passions, will stand the test of reason, cannot admit of any dispute. For, upon a fair examination into the consequences of things, or the relations and aptitudes of means to ends, reason evidently demonstrates, and experience confirms it, that "to have our defensive passions duly proportioned to our dangers, is the surest way to avoid or get clear of them, and obtain the security we seek after."—"To proportion our private passions to our wants, is the best means to supply them;—and, to adapt our public affections to our social relations and the good of others, is the most effectual method of fulfilling one, and procuring the other." In this sense, therefore, virtue may be said to be a "conduct conformable to reason, as reason discovers an apparent aptitude in such an order and œconomy of powers and passions to answer the end for which they are naturally formed.

If the idea of moral obligation is to be deduced merely from this aptitude or connection between certain passions, or a certain order and balance of passions, and certain ends

ends obtained or to be obtained by them; then is reason or reflection, which perceives that aptitude or connection, the proper judge of moral obligation; and on this supposition it may be defined, "the connection between the affection and the end, or between the action and the motive:" for the end is the motive, or the final cause; and the affection is the action, or its immediate natural cause. A man, from mere self-love, may be induced to fulfil that obligation which is founded on the connection between the defensive passions and their ends, or the private passions and their ends; because, in that case, his own interest will prompt him to indulge them in the due proportion required. But if he has no affections which point beyond himself, no principle but self-love or some subtle modification of it, what shall interest him in the happiness of others, where there is no connection between it and his own? or what sense can he have of moral obligation to promote it? Upon this scheme therefore, without public or social affections there could be no motive, and consequently no moral obligation, to a beneficent distant conduct.

But if the mere connection between certain passions, or a certain order of passions, and certain ends, is what constitutes or gives us the idea of moral obligation; then why may not the apportioning of any temper or conduct, nay, of any piece of machinery, to obtain its end, form an equally strict moral obligation? For the connection and aptitude are as strong and invariable in the latter instances as in the former. But as this is confounding the most obvious differences of things, we must trace the source of moral obligation to another and a more natural source.

Let us appeal therefore to sense and experience, "how we stand affected to those different sets of passions in the just measure and balance of which we found a right temper to consist." For this is entirely a matter of experience, in which we must examine, as in any other natural inquiry, "what are the genuine feelings and operations of nature, and what affections or symptoms of them appear in the given instance."

The defensive passions, as anger and fear, give us rather pain than pleasure; yet we cannot help feeling them when provoked by injury or exposed to harm. We account the creature imperfect that wants them, because they are necessary to his defence. Nay, we should in some measure condemn ourselves, did we want the necessary degree of resentment and caution. But if our resentment exceeds the wrong received, or our caution the evil dreaded, we then blame ourselves for having over-acted our part. Therefore, while we are in danger, to be totally destitute of them we reckon a blameable defect, and to feel them in a just, *i. e.* necessary measure, we approve, as suited to the nature and condition of such a creature as man. But, our security obtained, to continue to indulge them; we not only disapprove as hurtful, but condemn as unmanly, unbecoming, and mean-spirited: Nor will such a conduct afford any self-approving joy, when we coolly reflect upon it.

With regard to the private passions, such as love of life, pleasure, ease, and the like; as these aim at private good, and are necessary to the perfection and happiness

of the individual, we should reckon any creature defective, and even blameable, that was destitute of them. Thus, we condemn the man who imprudently ruins his fortune, impairs his health, or exposes his life; we not only pity him as an unfortunate creature, but feel a kind of moral indignation and contempt of him, for having made himself such. On the other hand, though a discreet self regard does not attract our esteem and veneration, yet we approve of it in some degree, in an higher and different degree from what we would regard a well-contrived machine as necessary to constitute a finished creature, nay, to complete the virtuous character, and as exactly suited to our present indigent state. There are some passions respecting private good, towards which we feel higher degrees of approbation; as the love of knowledge, of action, of honour, and the like. We esteem them as marks of an ingenious mind, and cannot help thinking the character in which they are wanting remarkably stupid, and in some degree immoral.

With regard to the social affections, as compassion, natural affection, friendship, benevolence, and the like, we approve, admire, and love them in ourselves, and in all in whom we discover them, with an esteem and approbation, if not different in kind, yet surely far superior in degree to what we feel towards the other passions. These we reckon necessary, just, and excellently fitted to our structure and state; and the creature which wants them we call defective, ill-constituted, a kind of abortion. But the public affections we esteem as self-worthy, originally and eternally amiable.

But among the social affections, we make an obvious and constant distinction, *viz.* between those particular passions, which urge us with a sudden violence, and uneasy kind of sensation, to pursue the good of their respective objects, as pity, natural affection, and the like; and those calm dispassionate affections and desires which prompt us more steadily and uniformly to promote the happiness of others. The former we generally call *passions*; to distinguish them from the other sort, which go more commonly by the name of *affections*, or *calm desires*. The first kind we approve indeed, and delight in; but we feel still higher degrees of approbation and moral complacency towards the last, and towards all limitations of the particular instincts, by the principle of universal benevolence. The more objects the calm affections take in, and the worthier these are, their dignity rises in proportion, and with this our approbation keeps an exact pace. A character, on the other hand, which is quite divested of these public affections, which feels no love for the species, but, instead of it, entertains malice, rancour, and ill will, we reckon totally immoral and unnatural.

Such then are the sentiments and dispositions we feel, when these several orders of affection pass before the mental eye.

Therefore, "that state in which we feel ourselves moved, in the manner above described, towards those affections and passions, as they come under the mind's review, and in which we are instantaneously, and independently of our choice or volition, prompted to a correspondent conduct, we call a state of moral obligation." Let us suppose, for instance, a parent, a friend, a benefactor, reduced

duced to a condition of the utmost indigence and distress, and that it is in our power to give them immediate relief. To what conduct are we obliged? what duty does nature dictate and require in such a case? Attend, and nature will tell with a voice irresistibly audible and commanding to the human heart, "that immediate relief ought to be given." Again, let a friend, a neighbour, or even a stranger, have lodged a deposit in our hands, and after some time reclaim it; no sooner do these ideas of the confidence reposed in us, and of property not transferred but deposited, occur, than we immediately and unavoidably feel and recognize the obligation to restore it. In both these cases, we should condemn ourselves, if we acted otherwise, as having done, or omitted doing, what we ought not;—as having acted beneath the dignity of our nature,—contrary to our most intimate sense of right and wrong;—we should accuse ourselves as guilty of ingratitude, injustice, and inhumanity;—and be conscious of deserving the censure, and therefore dread the resentment, of all rational beings.—But in complying with the obligation, we feel joy and self approbation,—are conscious of an inviolable harmony between our nature and duty,—and think ourselves entitled to the applause of every impartial spectator of our conduct.

To describe therefore what we cannot perhaps define, a state of moral obligation, is "that state in which a creature, endued with such senses, powers, and affections as man, would condemn himself, and think he deserved the condemnation of all others, should he refuse to fulfil it; but would approve himself, and expect the approbation of all others, upon complying with it."

And we call him a moral agent, who is in such a state, or is subject to moral obligation. Therefore as man's structure and connections often subject him to such a state of moral obligation, we conclude that he is a moral agent. But as man may sometimes act without knowing what he does, as in cases of frenzy or disease, or in many natural functions; or, knowing what he does, he may act without choice or affection, as in cases of necessity or compulsion; therefore, to denominate an action moral, *i. e.* approveable, or blameable, it must be done knowingly and willingly, or from affection and choice. A morally good action, then, is "to fulfil a moral obligation knowingly and willingly;" and a morally bad action, is "to violate a moral obligation knowingly and willingly."

As not an action, but a series of actions constitute a character; as not an affection, but a series of affections constitute a temper; and as we denominate things by the gross, *à fortiori*, or by the qualities which chiefly prevail in them: "therefore we call that a morally good character, in which a series of morally good actions prevail; and that a morally good temper, in which a series of morally good affections have the ascendant." A bad character and bad temper are the reverse. But where the above-mentioned order or proportion of passions is maintained, there a series of morally good affections and actions will prevail. Therefore, "to maintain that order and proportion, is to have a morally good temper and character." But a "morally good temper and cha-

rafter is moral rectitude, integrity, virtue, or the complement of duty."

If it be asked, after all, "How we come by the idea of moral obligation or duty?" we may answer, that we come by it in the same way as by our other original and primary perceptions. We receive them all from nature, or the great Author of nature. For this idea of moral obligation is not a creature of the mind, or dependent on any previous act of volition; but arises on certain occasions, or when certain other ideas are presented to the mind, as necessarily, instantaneously, and unavoidably, as pain does upon too near an approach to the fire, or pleasure from the fruition of any good. It does not, for instance, depend on our choice, whether we shall feel the obligation to succour a distressed parent, or to restore a deposit intrusted to us when it is recalled. We cannot call this a compound idea made up of one or more simple ideas. We may indeed, nay, we must, have some ideas antecedent to it, *e. g.* that of a parent—in distress—of a child—able to relieve—of the relation of one to the other,—of a trust,—of right, &c. But none of these ideas constitute the perception of obligation. These indeed, by a law of our nature, are the occasion of suggesting it; but they are as totally different from it, as colours are from sounds. By sense or reflection we perceive the correlatives, our memory recalls the favours or deposit we received, the various circumstances of the case are matters of fact or experience; but some delicate inward organ or power, or call it what we please, does, by a certain instantaneous sympathy, antecedent to the cool deductions of reason, and independent of previous instruction, art, or volition, perceive the moral harmony, the living irresistible charm of moral obligation, which immediately interests the correspondent passions, and prompts us to fulfil its awful dictates.

We need not apprehend any danger from the quickness of its decisions; nor be frightened, because it looks like instinct, and has been called so. Would we approve one for deliberating long, or reasoning the matter much at leisure, whether he should relieve a distressed parent, feed a starving neighbour, or restore the trust committed to him? Should we not suspect the reasoner of knavery, or of very weak affections to virtue? We employ reason in examining the condition, relations, and other circumstances of the agent or patient, or of those with whom either of them are connected, or, in other words, the state of the case; and in complicated cases, where the circumstances are many, it may require no small attention to find the true state of the case: but when the relations of the agent or patient, and the circumstances of the actions, are obvious, or come out such after a fair trial, we should scarce approve him who demurs on the obligation to that conduct which the case suggests.

From what has been said it is evident, that it is not the pleasure or agreeable sensations which accompany the exercise of the several affections, nor those consequent to the actions, that constitute moral obligation, or excite in us the idea of it. That pleasure is posterior to the idea of obligation; and frequently we are obliged, and acknowledge ourselves under an obligation, to such affections

affections and actions as are attended with pain; as in the trials of virtue, where we are obliged to sacrifice private to public good, or a present pleasure to a future interest. We have pleasure in serving an aged parent, but it is neither the perception nor prospect of that pleasure which gives us the idea of obligation to that conduct.

The FINAL Causes of our Moral Faculties of Perception and Ab. Hon.

We have now taken a general prospect of man, and of his moral powers and connections; and on these erected a scheme of duty, or moral obligation, which seems to be confirmed by experience, consonant to reason, and approved by his most inward and most sacred senses. It may be proper, in the next place, to take a more particular view of the final causes of those delicate springs by which he is impelled to action, and of those clogs by which he is restrained from it.—By this detail we shall be able to judge of their aptitude to answer their end, in a creature endued with his capacities, subject to his wants, exposed to his dangers, and susceptible of his enjoyments; and from thence, we shall be in condition to pronounce concerning the end of his whole structure, its harmony with his state, and consequently its subserviency to answer the great and benevolent intentions of its author.

The supreme being has seen fit to blend in the whole of things a prodigious variety of discordant and contrary principles, light and darkness, pleasure and pain, good and evil. There are multifarious natures, higher and lower, and many intermediate ones between the wide distant extremes. These are differently situated, variously adjusted, and subjected to each other; and all of them subordinate to the order and perfection of the whole. We may suppose man placed as in a centre amidst those innumerable orders of beings; by his outward frame drawn to the material system, and by his inward connected with the intellectual or moral, and of course affected by the laws which govern both, or affected by that good and all that ill which result from those laws. In this infinite variety of relations with which he is surrounded, and of contingencies to which he is liable, he feels strong attractions to the good, and violent repulsions or aversions to the ill. But as good and ill are often blended, and wonderfully complicated one with the other; as they sometimes immediately produce and run up into each other, and at other times lie at great distances, yet, by means of intervening links, introduce one another; and as these effects are often brought about in consequence of hidden relations, and general laws, of the energy of which he is an incompetent judge; it is easy for him to mistake good for evil, and evil for good; and consequently he may be frequently attracted by such things as are destructive, or repel such as are salutary. Thus, by the tender and complicated frame of his body, he is subjected to a great variety of ills, to sickness, cold, heat, fatigue, and innumerable wants. Yet his knowledge is so narrow, and his reason so weak, that in many cases he cannot judge, in the way of investigation, or reasoning, of the connections of those effects with their respective causes, or of the various latent energies of natural things. He is therefore informed of this connection by the experience of certain senses, or organs of perception, which,

by a mechanical instantaneous motion, feel the good and the ill, receiving pleasure from one, and pain from the other. By these, without any reasoning, he is taught to attract or shun what tends to his welfare, and to repel and avoid what tends to his ruin. Thus, by his senses of taste and smell, or by the pleasure he receives from certain kinds of food, he is admonished which agree with his constitution, and, by an opposite sense of pain, he is informed which sorts disagree, or are destructive of it; but is not by means of these instructed in the inward natures and constitutions of things.

Some of those senses are armed with strong degrees of uneasiness or pain, in order to urge him to seek after such objects as are suited to them. And these respect his more immediate and pressing wants; as the sense of hunger, thirst, cold, and the like; which by their painful importunities, compel him to provide food, drink, raiment, shelter. Those instincts by which we are thus prompted, with some kind of commotion or violence, to attract and pursue good, or to repel and avoid ill, we call appetites and passions. By our senses then we are informed of what is good or ill to the private system, or the individual; and by our private appetites and passions we are impelled to one, and restrained from the other.

In consequence of this machinery, and the great train of wants to which our nature subjects us, we are engaged in a continued series of occupations, which often require much application of thought, or great bodily labour, or both. The necessities of life, food, cloaths, shelter, and the like, must be provided; conveniences must be acquired to render life still more easy and comfortable. In order to obtain these, arts, industry, manufactures, and trade are necessary: and to secure to us the peaceable enjoyment of their fruits, civil government, policy, and laws must be contrived, and the various business of public life carried on. Thus while man is concerned and busied in making provision, or obtaining security for himself, he is by degrees engaged in connections with a family, friends, neighbours, a community, or a commonwealth. Hence arise new wants, new interests, new cares, and new employments. The passions of one man interfere with those of another. Interests are opposed. Competitions arise; contrary courses are taken. Disappointments happen, distinctions are made, and parties formed: This opens a vast scene of distraction and embarrassment, and introduces a mighty train of good and ill, both public and private. Yet amidst all this confusion and hurry, plans of action must be laid, consequences foreseen or guarded against, inconveniences provided for; and frequently particular resolutions must be taken, and schemes executed, without reasoning or delay.

Now, what provision has the Author of our nature made for this necessary condition? How has he fitted the actor, man, for playing his part in this perplexed and busy scene?

Our supreme Parent, watchful for the whole, has not left himself without a witness here neither, and hath made nothing imperfect, but all things are double one against another. He has not left man to be informed, only by the cool notices of reason, of the good or ill, the happiness or misery of his fellow creatures. He has

made him sensible of their good and happiness, but especially of their ill and misery, by an immediate sympathy, or quick feeling of pleasure and of pain.

The latter we call pity or compassion. For the former, though every one who is not quite divested of humanity feels it in some degree, we have not got a name, unless we call it congratulation, or joyful sympathy, or that good humour which arises on seeing others pleased or happy. Both these feelings have been called, in general, the public or common sense, by which we feel for others, and are interested in their concerns as really, though perhaps less sensibly, than in our own.

When we see our fellow-creatures unhappy through the fault or injury of others, we feel resentment or indignation against the unjust causers of that misery. If we are conscious that it has happened through our fault or injurious conduct, we feel shame; and both these classes of senses and passions, regarding misery and wrong, are armed with such sharp sensations of pain, as not only prove a powerful guard and security to the species, or public system, against those ills it may, but serve also to lessen or remove those ills it does, suffer. Compassion draws us out of ourselves to bear a part of the misfortunes of others, powerfully solicits us in their favour, melts us at sight of their distress, and makes us in some degree unhappy till they are relieved from it. It is peculiarly well adapted to the condition of human life, because it is much more and oftener in our power to do mischief than good, and to prevent or lessen misery than to communicate positive happiness; and therefore it is an admirable restraint upon the more selfish passions, or those violent impulses that carry us to the hurt of others.

There are other particular instincts or passions, which interest us in the concerns of others, even while we are most busy about our own, and which are strongly attractive of good, and repulsive of ill to them. Such are natural affection, friendship, love, gratitude, desire of fame, love of society, of one's country. Now as the private appetites and passions were found to be armed with strong sensations of desire and uneasiness, to prompt man the more effectually to sustain labours, and encounter dangers, in pursuit of those goods that are necessary to the preservation and welfare of the individual, and to avoid those ills which tend to his destruction; in like manner it was necessary that this other class of desires and affections should be prompted with as quick sensations of pain, not only to counteract the strength of their antagonists, but to engage us in a virtuous activity for our relations, families, friends, neighbours, country. Indeed our sense of right and wrong will admonish us that it is our duty, and reason and experience farther assure us that it is both our interest and best security, to promote the happiness of others; but that sense, that reason, and that experience, would frequently prove but weak and ineffectual prompters to such a conduct, especially in cases of danger and hardship, and amidst all the importunities of nature, and that constant hurry in which the private passions involve us, without the aid of those particular kind affections, which mark out to us particular spheres of duty, and with an agreeable violence engage and fix us down to them.

It is evident therefore, that these two classes of affection, the private and public, are set one against the other, and designed to controul and limit each others influence, and thereby to produce a just balance in the whole. In general, the violent sensations of pain or uneasiness which accompany hunger, thirst, and the other private appetites, or too great fatigue of mind as well as of body, prevent the individual from running to great excesses in the exercise of the higher functions of the mind; as too intense thought in the search of truth, violent application to business of any kind, and different degrees of romantic heroism. On the other hand, the finer senses of perception, and those generous desires and affections which are connected with them, the love of action, of imitation, of truth, honour, public virtue, and the like, are wisely placed in the opposite scale, in order to prevent us from sinking into the dregs of the animal life, and debasing the dignity of man below the condition of brutes. So that by the mutual reaction of those opposite powers, the bad effects are prevented that would naturally result from their acting singly and apart, and the good effects are produced which each are severally formed to produce.

The same wholesome opposition appears likewise in the particular counterworkings of the private and public affections one against the other. Thus compassion is adapted to counterpoise the love of ease, of pleasure, and of life; and to disarm, or to set bounds to resentment: and resentment of injury done to ourselves or to our friends, prevents an effeminate compassion or consternation; and gives us a noble contempt of labour, pain, and death. Natural affection, friendship, love of one's country, nay, zeal for any particular virtue, are frequently more than a match for the whole train of selfish passions. On the other hand, without that intimate over-ruling passion of self-love, and those private desires which are connected with it, the social and tender instincts of the human heart would degenerate into the wildest dotage, the most torturing anxiety, and downright frenzy.

But not only are the different orders or classes of affection checks one upon another, but passions of the same classes are mutual clogs. Thus, how many are withheld from the violent outrages of resentment by fear? and how easily is fear controuled in its turn, while mighty wrongs awaken a mighty resentment? The private passions often interfere, and therefore moderate the violence of each other; and a calm self-love is placed at their head to direct, influence, and controul their particular attractions and repulsions. The public affections likewise restrain one the other; and all of them are put under the controul of a calm dispassionate benevolence, which ought in like manner to direct and limit their particular motions.—Thus most part, if not all the passions have a twofold aspect, and serve a twofold end. In one view they may be considered as powers, impelling mankind to a certain course, with a force proportioned to the apprehended moment of the good they aim at. In another view they appear as weights balancing the action of the powers, and controuling the violence of their impulses. By means of these powers and weights a natural poise is settled in the human breast by its all-wise Author,

by which the creature is kept tolerably steady and regular in his course, amidst that variety of stages through which he must pass.

But this is not all the provision which God has made for the hurry and perplexity of the scene in which man is destined to act. Amidst those infinite attractions and repulsions towards private and public good and ill, mankind either cannot often foresee the consequences or tendencies of all their actions towards one or other of these, especially where those tendencies are intricate and point different ways, or those consequences remote and complicated: or though, by careful and cool inquiry, and a due improvement of their rational powers, they might find them out; yet distracted as they are with business, amused with trifles, dissipated by pleasure, and disturbed by passion, they either have, or can find, no leisure to attend to those consequences, or to examine how far this or that conduct is productive of private or public good on the whole. Therefore, were it left entirely to the slow and sober deductions of reason to trace those tendencies and make out those consequences, it is evident, that, in many particular instances, the business of life must stand still, and many important occasions of action be lost, or perhaps the grosslest blunders be committed. On this account the Deity, besides that general approbation which we bestow on every degree of kind affection, has moreover implanted in man many particular perceptions, or determinations, to approve of certain qualities or actions, which, in effect, tend to the advantage of society, and are connected with private good, though he does not always see that tendency, nor mind that connection. And these perceptions or determinations do, without reasoning, point out, and, antecedent to views of interest, prompt to a conduct beneficial to the public, and useful to the private system. Such is that sense of candor and veracity, that abhorrence of fraud and falsehood, that sense of fidelity, justice, gratitude, greatness of mind, fortitude, clemency, decorum; and that disapprobation of knavery, injustice, ingratitude, meanness of spirit, cowardice, cruelty and indecorum, which are natural to the human mind. The former of those dispositions, and the actions flowing from them are approved, and those of the latter kind disapproved by us, even abstracted from the view of their tendency or conduciveness to the happiness or misery of others or of ourselves. In one we discern a beauty, a superior excellency, a congruity to the dignity of man; in the other a deformity, a littleness, a debasement of human nature.

There are other principles also, connected with the good of society, or the happiness and perfection of the individual, though that connection is not immediately apparent, which we behold with real complacency and approbation, though perhaps inferior in degree, if not in kind; such as gravity, modesty, simplicity of deportment, temperance, prudent economy; and we feel some degree of contempt and dislike where they are wanting, or where the opposite qualities prevail. These and the like perceptions or feelings are either different modifications of the moral sense, or subordinate to it, and plainly serve the same important purpose, being expeditious monitors in the several emergencies of a various and distracted life, of

what is right, what is wrong, what is to be pursued, and what avoided; and, by the pleasant or painful consciousness which attends them, exerting their influence as powerful prompters to a suitable conduct.

From a slight inspection of the above-named principles, it is evident they all carry a friendly aspect to society and the individual, and have a more immediate or a more remote tendency to promote the perfection or good of both. This tendency cannot be always foreseen, and would be often mistaken, or seldom attended to by a weak, busy, short-sighted creature, like man, both rash and variable in his opinions, a dupe to his own passions or to the designs of others, liable to sickness, to want, and to error. Principles, therefore, which are so nearly linked with private security and public good, by directing him, without operose reasoning, where to find one, and how to promote the other, and by prompting him to a conduct conducive to both, are admirably adapted to the exigencies of his present state, and wisely calculated to obtain the ends of universal benevolence.

It were easy, by considering the subject in another light, to shew, in a curious detail of particulars, how wonderfully the inside of man, or that astonishing train of moral powers and affections with which he is endued, is fitted to the several stages of that progressive and probationary state, through which he is destined to pass. As our faculties are narrow and limited, and rise from very small and imperfect beginnings, they must be improved by exercise, by attention, and repeated trials. And this holds true, not only of our intellectual, but of our moral and active powers. The former are liable to errors in speculation, the latter to blunders in practice, and both often terminate in misfortunes and pains: and those errors and blunders are generally owing to our passions, or to our too forward and warm admiration of those partial goods they naturally pursue, or to our fear of those partial ills they naturally repel. Those misfortunes therefore lead us back to consider where our misconduct lay, and whence our errors flowed; and consequently are salutary pieces of trial, which tend to enlarge our views, to correct and refine our passions, and consequently improve both our intellectual and moral powers.—Our passions then are the rude materials of our virtue, which heaven has given us to work up, to refine and polish into an harmonious and divine piece of workmanship. They furnish out the whole machinery, the calms and storms, the lights and shades of human life. They shew mankind in every attitude and variety of character, and give virtue both its struggles and its triumphs. To conduct them well in every state, is merit; to abuse or misapply them, is demerit.

The different sets of senses, powers, and passions, which unfold themselves in those successive stages, are both necessary, and adapted to that rising and progressive state. Enlarging views and growing connections require new passions and new habits; and thus the mind, by these continually expanding and finding a progressive exercise, rises to higher improvements, and pushes forward to maturity and perfection.

In this beautiful oeconomy and harmony of our structure, both outward and inward, with that state, we may

at once discern the great lines of our duty traced out in the fairest and brightest characters, and contemplate with admiration a more august and marvellous scene of divine wisdom and goodness laid in the human breast, than we shall perhaps find in the whole compass of nature.

From this detail it appears, that man, by his original frame, is made for a temperate, compassionate, benevolent, active, and progressive state. He is strongly attractive of the good, and repulsive of the ill, which befall others as well as himself. He feels the highest approbation and moral complacency in those affections and in those actions which immediately and directly respect the good of others, and the highest disapprobation and abhorrence of the contrary. Besides these, he has many particular perceptions or instincts of approbation, which though perhaps not of the same kind with the others, yet are accompanied with correspondent degrees of affection, proportioned to their respective tendencies to the public good. Therefore, by acting agreeably to these principles, man acts agreeably to his structure, and fulfils the benevolent intentions of his Author.

The principal Distinctions of Duty or Virtue.

We have now considered the constitution and connections of man; and on these erected a general system of duty or moral obligation, consonant to reason, approved by his most sacred and intimate sense, suitable to his mixed condition, and confirmed by the experience of mankind. We have also traced the final causes of his moral faculties and affections to those noble purposes they answer with regard both to the private and the public system.

From this induction it is evident, that there is one order or class of duties which man owes to himself; another to society; and a third to God.

*The duties he owes to himself are founded chiefly on the defensive and private passions, which prompt him to pursue whatever tends to private good or happiness, and to avoid or ward off whatever tends to private ill or misery. Among the various goods which allure and solicit him, and the various ill which attack or threaten him, "To be intelligent and accurate in selecting one, and rejecting the other, or in preferring the most excellent goods, and avoiding the most terrible ill, when there is a competition among either, and to be discreet in using the best means to attain the goods and avoid the ill, is what we call prudence." This, in our inward frame, corresponds to sagacity, or a quickness of sense in our outward.—"To proportion our defensive passions to our dangers, we call fortitude;" which always implies "a just mixture of calm reasonment or animosity, and well governed caution." And this firmness of mind answers to the strength and muscling of the body.—And "duly to adjust our private passions to our wants, or to the respective moment of the good we affect or pursue, we call temperance;" which does therefore always imply "a just balance or command of the passions."

The second class of duties arises from the public or social affections; "the just harmony or proportion of which to the dangers and wants of others, and to the fe-

veral relations we bear, commonly goes by the name of justice." This includes the whole of our duty to society, to its parent, and the general polity of nature; particularly gratitude, friendship, sincerity, natural affection, benevolence, and the other social virtues. The virtues comprehended under the former class, especially prudence and fortitude, may likewise be transferred to this; and according to the various circumstances in which they are placed, and the more confined or more extensive sphere in which they operate, may be denominated private, economical, or civil prudence, fortitude, &c. These direct our conduct with regard to the wants and dangers of those lesser or greater circles with which we are connected.

The third class of duties respects the Deity, and arises also from the public affections, and the several glorious relations which he sustains to us, as our creator, benefactor, law-giver, judge, &c.

We chose to consider this set of duties in the last place, because, though prior in dignity and excellency, they seem to be last in order of time, as thinking it the most simple and easy method to follow the gradual progress of nature, as it takes its rise from individuals, and spreads through the social system, and still ascends upwards, till at length it stretches to its almighty Parent and Head, and so terminates in those duties which are highest and best.

The duties resulting from these relations, are reverence, gratitude, love, resignation, dependence, obedience, worship, praise; which, according to the model of our finite capacities, must maintain some sort of proportion to the grandeur and perfection of the object whom we venerate, love, and obey. "This proportion or harmony, is expressed by the general name of piety or devotion;" which is always stronger or weaker, according to the greater or less apprehended excellency of its object. This sublime principle of virtue, is the enlivening soul which animates the moral system, and that cement which binds and sustains the other duties which man owes to himself or to society.

This then is the general temper and constitution of virtue, and these are the principal lines or divisions of duty. To those good dispositions, which respect the several objects of our duty, and to all actions which flow from such dispositions, the mind gives its sanction or testimony. And this sanction or judgment concerning the moral quality, or the goodness of actions or dispositions, moralists call conscience. When it judges of an action that is to be performed, it is called an antecedent conscience; and when it passes sentence on an action which is performed, it is called a subsequent conscience. The tendency of an action to produce happiness, or its external conformity to a law, is termed its material goodness; but the good dispositions from which an action proceeds, or its conformity to law in every respect, constitutes its formal goodness.

When the mind is ignorant or uncertain about the moment of an action, or its tendency to private or public good; or when there are several circumstances in the case, some of which being doubtful, render the mind dubious concerning the morality of the action; this is called a doubtful or scrupulous conscience: if it mistakes concern-

ing these, it is called an erroneous conscience. If the error or ignorance is involuntary or invincible, the action proceeding from that error, or from that ignorance, is reckoned innocent, or not imputable. If the error or ignorance is supine or affected, *i. e.* the effect of negligence, or of affectation and wilful inadvertence, the conduct flowing from such error, or such ignorance, is criminal and imputable. Not to follow one's conscience, though erroneous and ill-formed, is criminal, as it is the guide of life; and to contradict it, shews a depraved and incorrigible spirit: Yet, to follow an erroneous conscience is likewise criminal, if that error which misled the conscience was the effect of inattention, or of any criminal passion.

If it be asked, "How an erroneous conscience shall be refused, since it is supposed to be the only guide of life, and judge of morals?" we answer, In the very same way that we would rectify reason, if at any time it should judge wrong, as it often does, *viz.* By giving it proper and sufficient materials for judging right, *i. e.* by inquiring into the whole state of the case; the relations, connections, and several obligations of the actor; the consequences, and other circumstances of the action; or the surplusage of private or public good which results, or is likely to result, from the action or from the omission of it. If those circumstances are fairly and fully stated, the conscience will be just and impartial in its decision. For, by a necessary law of our nature, it approves, and is well affected to the moral form; and if it seems to approve of vice or immorality, it is always under the notion or mask of some virtue. So that, strictly speaking, it is not conscience which errs; for its sentence is always conformable to the view of the case which lies before it; and is just, upon the supposition that the case is truly such as it is represented to it. All the fault is to be imputed to the agent, who neglects to be better informed, or who, thro' weakness or wickedness, hastens to pass sentence from an imperfect evidence.

Of Man's Duty to HIMSELF. Of the Nature of GOOD, and the CHIEF GOOD.

EVERY creature, by the constitution of his nature, is determined to love himself, to pursue whatever tends to his preservation and happiness, and to avoid whatever tends to his hurt and misery. Being endued with sense and perception, he must necessarily receive pleasure from some objects, and pain from others. Those objects which give pleasure are called good, and those which give pain evil. To the former he feels that attraction or motion we call desire, or love: To the latter that impulse we call aversion or hatred. To objects which suggest neither pleasure nor pain, and are apprehended of no use to procure one, or ward off the other, we feel neither desire nor aversion; and such objects are called indifferent. Those objects which do not of themselves produce pleasure or pain, but are the means of procuring either, we call useful or noxious. Towards them we are affected in a subordinate manner, or with an indirect and reflective, rather than a direct and immediate affection. All the original and particular affections of our nature, lead us out to, and ultimately rest in, the first kind of objects,

viz. those which give immediate pleasure, and which we therefore call good, directly so. The calm affection of self-love alone is conversant about such objects as are only consequentially good, or merely useful to ourselves.

But besides those sorts of objects which we call good, merely and solely as they give pleasure, or are means of procuring it, there is an higher and nobler species of good, towards which we feel that peculiar movement we call approbation or moral complacency, and which we therefore denominate moral good. Such are our affections, and the consequent actions to them. The perception of this is quite distinct in kind from the perception of the other species; and though it may be connected with pleasure or advantage by the benevolent constitution of nature, yet it constitutes a good independent of that pleasure and that advantage, and far superior, not in degree only, but in dignity, to both. The other, *viz.* the natural good, consists in obtaining those pleasures which are adapted to the peculiar senses and passions susceptible of them, and is as various as are those senses and passions. This, *viz.* the moral good, lies in the right conduct of the several senses and passions, or their just proportion and accommodation to their respective objects and relations; and this is of a more simple and invariable kind.

By our several senses we are capable of a great variety of pleasing sensations. These constitute distinct ends or objects ultimately pursuable for their own sake. To these ends, or ultimate objects, correspond peculiar appetites or affections, which prompt the mind to pursue them. When these ends are attained, there it rests and looks no farther. Whatever therefore is pursuable, not on its own account, but as subservient or necessary to the attainment of something else that is intrinsically valuable or for its own sake, we call a mean, and not an end. So that ends, and not means, constitute the materials or the very essence of our happiness. Consequently, happiness cannot be one simple uniform thing in creatures constituted, as we are, with such various senses of pleasure, or such different capacities of enjoyment. Now, the same principle or law of our nature which determines us to pursue any one end or species of good, prompts us to pursue every other end or species of good of which we are susceptible, or to which our Maker has adapted an original propension. But amidst the great multiplicity of ends or goods, which form the various ingredients of our happiness, we perceive an evident gradation or subordination, suited to that gradation of senses, powers, and passions, which prevails in our mixed and various constitution, and to that ascending series of connections which open upon us in the different stages of our progressive state.

Thus the goods of the body, or of the external senses, seem to hold the lowest rank in this gradation or scale of goods. These we have in common with the brutes: and though many men are brutish enough to pursue the goods of the body with a more than brutal fury; yet when at any time they come in competition with goods of an higher order, the unanimous verdict of mankind, by giving the last the preference, condemns the first to the

meanest place. Goods consisting in exterior social connections, as fame, fortune, power, civil authority, seem to succeed next, and are chiefly valuable as the means of procuring natural or moral good, but principally the latter. Goods of the intellect are still superior; as taste, knowledge, memory, judgment, &c. The highest are moral goods of the mind, directly and ultimately regarding ourselves; as command of the appetites and passions, prudence, fortitude, benevolence, &c. These are the great objects of our pursuit, and the principal ingredients of our happiness. Let us consider each of them, as they rise one above the other in this natural series or scale, and touch briefly on our obligations to pursue them.

Those of the body are health, strength, agility, hardi-ness, and patience of change, neatness, and decency.

Good health, and a regular easy flow of spirits, are in themselves sweet natural enjoyments, a great fund of pleasure, and indeed the proper seasoning which gives a flavour and poignancy to every other pleasure. The want of health unites us for most duties of life, and is especially an enemy to the social and human affections, as it generally renders the unhappy sufferer peevish and sullen, disgusted at the allotments of providence, and consequently apt to entertain suspicious and gloomy sentiments of its Author. It obstructs the free exercise and full improvement of our reason, makes us a burden to our friends, and useless to society. Whereas the uninterrupted enjoyment of good health, is a constant source of good humour; and good humour is a great friend to openness and benignity of heart; enables us to encounter the various ills and disappointments of life with more courage, or to sustain them with more patience; and, in short, conduces much, if we are otherwise duly qualified, to our acting our part in every exigency of life with more firmness, consistency, and dignity. Therefore it imports us much to preserve and improve an habit or enjoyment, without which every other external entertainment is tasteless, and most other advantages of little avail. And this is best done by a strict temperance in diet and regimen, by regular exercise, and by keeping the mind serene and untroubled by violent passions, and unsubdued by intense and constant labours, which greatly impair, and gradually destroy, the strongest constitutions.

Strength, agility, hardi-ness, and patience of change, suppose health, and are unattainable without it; but they imply something more, and are necessary to guard it, to give us the perfect use of life and limbs, and to secure us against many otherwise unavoidable ills. The exercise of the necessary manual, and of most the elegant arts of life, depends on strength and agility of body; personal dangers, private and public dangers, the demands of our friends, our families and country require them; they are necessary in war, and ornamental in peace; fit for the employments of a country and a town life, and they exalt the entertainments and diversions of both. They are chiefly obtained by moderate and regular exercise.

Few are so much raised above want and dependence, or so exempted from business and care, as not to be often exposed to inequalities and changes of diet, exercise, air, climate, and other irregularities. Now, what can be so effectual to secure one against the mischiefs arising from

such unavoidable alterations, as hardi-ness, and a certain versatility of constitution, which can bear extraordinary labours, and submit to great changes, without any sensible uneasiness or bad consequences. This is best attained, not by an over great delicacy and minute attentions to forms, or by an invariable regularity in diet, hours, and way of living, but rather by a bold discreet latitude of regimen. Besides, deviations from established rules and forms of living, if kept within the bounds of sobriety and reason, are friendly to thought and original sentiment, animate the dull scene of ordinary life and business, and agreeably stir the passions, which stagnate or breed ill humour in the calms of life.

Neatness, cleanliness, and decency, to which we may add dignity of countenance and demeanour, seem to have something refined and moral in them. At least we generally esteem them indications of an orderly, genteel, and well governed mind, conscious of inward worth, or the respect due to one's nature. Whereas nastiness, slovenliness, awkwardness, and indecency, are shrewd symptoms of something mean, careless, and deficient, and betray a mind untaught, illiberal, unconscious of what is due to one's self or to others. How much cleanliness conduces to health needs hardly to be mentioned; and how necessary it is to maintain one's character and rank in life, and to render us agreeable to others as well as to ourselves, is as evident.—There are certain motions, airs and gestures, which become the human countenance and form, in which we perceive a comeliness, openness, simplicity, gracefulness; and there are others, which, to our sense of decorum, appear uncouthly, affected, disingenuous, and awkward, quite unsuitable to the native dignity of our face and form. The first are in themselves the most easy, natural, and commodious; give one boldness and presence of mind, a modest assurance, an address both awful and alluring, they bespeak candour and greatness of mind, raise the most agreeable prejudices in one's favour, render society engaging, command respect, and often love, and give weight and authority both in conversation and business: in fine, they are the colouring of virtue, which shew it to the greatest advantage in whomsoever it is; and not only imitate, but in some measure supply it where it is wanting. Whereas the last, *viz.* rudeness, affectation, indecorum, and the like, have all the contrary effects; they are burdensome to one's self, a dishonour to our nature, and a nuisance in society. The former qualities or goods are best attained by a liberal education, by preserving a just sense of the dignity of our nature, by keeping the best and politest company; but above all, by acquiring those virtuous and ennobling habits of mind, which are decency in perfection, which will give an air of unaffected grandeur, and spread a lustre truly engaging over the whole form and deportment.

We are next to consider those goods which consist in exterior social connections; as fame, fortune, civil authority, power.

The first has a twofold aspect; as a good pleasant in itself, or gratifying to an original passion; and then, as expedient or useful towards a farther end. Honour from the wife and good, on the account of a virtuous conduct, is regal to a good man. There are few quite indifferent

even to the commendation of the vulgar. Though we cannot approve that conduct which proceeds entirely from this principle, and not from good affection or love of the conduct itself; yet as it is often a guard and additional motive to virtue in creatures imperfect as we are, and often distracted by interfering passions, it might be dangerous to suppress it altogether, however wise it may be to restrain it within due bounds, and however laudable to use it only as a scaffolding to our virtue, which may be taken down when that glorious structure is finished, but hardly till then. To pursue fame for itself, is innocent; to regard it only as an auxiliary to virtue, is noble; to seek it chiefly as an engine of public usefulness, is still more noble. For though the opinion and breath of men are transient and fading things; often obtained without merit, and lost without cause; yet as our business is with men, and as our capacity of serving them is generally increased in proportion to their esteem of us; therefore sound and well established moral applause may, and will be, modestly, not ostentatiously, sought after by the good; not indeed as a solitary refined sort of luxury, but as a public and proper instrument to serve and bless mankind. At the same time they will learn to despise that reputation which is founded on rank, fortune, and any other circumstances or accomplishments that are foreign to real merit, or to useful services done to others; and think that praise of little avail which is purchased without desert, and bestowed without judgment.

Fortune, power, and civil authority, or whatever is calculated influence and weight among mankind, are goods of the second division; that is, valuable and pursuable only as they are useful, or as means to a farther end, *viz.* the procuring or preserving the immediate objects of enjoyment or happiness to ourselves or others. Therefore, to love such goods on their own account, and to pursue them as ends, not the means of enjoyment, must be highly preposterous and absurd. There can be no measure, no limit to such pursuit; all must be whim, caprice, extravagance. Accordingly, such appetites, unlike all the natural ones, are increased by possession, and whetted by enjoyment. They are always precarious, and never without fears because the objects lie without one's self. they are seldom without sorrow and vexation, because no accession of wealth or power can satisfy them. But if those goods are considered only as the materials or means of private or public happiness; then the same obligations which bind us to pursue the latter, bind us likewise to pursue the former. We may, and no doubt we ought, to seek such a measure of wealth as is necessary to supply all our real wants, to raise us above servile dependence, and provide us with such conveniences as are suited to our rank and condition in life. To be regardless of this measure of wealth, is to expose ourselves to all the temptations of poverty and corruption; to forfeit our natural independency and freedom; to degrade, and consequently to render the rank we hold, and the character we sustain in society, useless, if not contemptible. When these important ends are secured, we ought not to murmur or repine that we possess no more; yet we are not seduced by any obligation, moral or divine, from seeking more, in order to give us that happiest and most God-like of all powers, the power of doing

good. A supine indolence in this respect is both absurd and criminal; absurd, as it robs us of an inexhausted fund of the most refined and durable enjoyments; and criminal, as it renders us so far useless to the society to which we belong. "That pursuit of wealth which goes beyond the former end, *viz.* the obtaining the necessities, or such conveniences of life, as in the estimation of reason, not of vanity or passion, are suited to our rank and condition, and yet is not directed to the latter, *viz.* the doing good, is what we call avarice." And "that pursuit of power, which, after securing one's self, *i. e.* attaining the proper independence and liberty of a rational social creature, is not directed to the good of others, is what we call ambition, or the lust of power." To what extent the strict measures of virtue will allow us to pursue either wealth, or power, and civil authority, is not perhaps possible precisely to determine. That must be left to prudence, and the peculiar character, condition, and other circumstances of each man. Only thus far a limit may be set, that the pursuit of either must encroach upon no other duty or obligation which we owe to ourselves, to society, or to its Parent and Head. The same reasoning is to be applied to power as to wealth. It is only valuable as an instrument of our own security, and of the free enjoyment of those original goods it may, and often does, administer to us; and as an engine of more extensive happiness to our friends, our country, and mankind.

Now the best, and indeed the only way to obtain a solid and lasting fame, is an uniform inflexible course of virtue, the employing one's ability and wealth in supplying the wants, and using one's power in promoting or securing the happiness, the rights and liberties of mankind, joined to an universal affability and politeness of manners. And surely one will not mistake the matter much, who thinks the same course conducive to the acquiring greater accessions both of wealth and power: especially if he adds to those qualifications a vigorous industry, a constant attention to the characters and wants of men, to the conjunctures of times, and continually varying genius of affairs; and a steady intrepid honesty, that will neither yield to the allurements, nor be overawed with the terrors of that corrupt and corrupting scene in which we live. We have sometimes heard, indeed, of other ways and means, as fraud, dissimulation, servility, and prostitution, and the like ignoble arts, by which the men of the world (as they are called, threwd politicians, and men of address!) amass wealth, and procure power: but as we want rather to form a man of virtue, an honest, contented, happy man, we leave to the men of the world their own ways, and permit them uncovied, and unimpaired by us, to reap the fruit of their doings.

The next species of objects in the scale of good, are the goods of the intellect; as knowledge, memory, judgment, taste, sagacity, docility, and whatever else we call intellectual virtues. Let us consider them a little, and the means as well as obligations to improve them.

As man is a rational creature, capable of knowing the differences of things and actions;—as he not only sees and feels what is present, but remembers what is past and often foresees what is future;—as he advances, from small

beginnings, by slow degrees, and with much labour and difficulty, to knowledge and experience;—as his opinions sway his passions;—as his passions influence his conduct,—and as his conduct draws consequences after it, which extend not only to the present, but to the future time, and therefore is the principal source of his happiness or misery;—it is evident, that he is formed for intellectual improvements, and that it must be of the utmost consequence for him to improve and cultivate his intellectual powers, on which those opinions, those passions, and that conduct depend.

But besides the future consequences and moment of improving our intellectual powers, their immediate exercise on their proper objects yields the most rational and refined pleasures. Knowledge and a right taste in the arts of imitation and design, as poetry, painting, sculpture, music, architecture, afford not only an innocent, but a most sensible and sublime entertainment. By these the understanding is instructed in ancient and modern life, the history of men and things, the energies and effects of the passions, the consequences of virtue and vice; by these the imagination is at once entertained and nourished with the beauties of nature and art, lighted up and spread out with the novelty, grandeur, and harmony of the universe; and in fine, the passions are agreeably roused, and suitably engaged by the greatest and most interesting objects that can fill the human mind. He who has a taste formed to these ingenious delights, and plenty of materials to gratify it, can never want the most agreeable exercise and entertainment, nor once have reason to make that fashionable complaint of the tediousness of time. Nor can he want a proper subject for the discipline and improvement of his heart. For being daily conversant with beauty, order and design, in inferior subjects, he bids fair for growing in due time an admirer of what is fair and well-proportioned in the conduct of life, and the order of society, which is only order and design exerted in their highest subject. He will learn to transfer the numbers of poetry to the harmony of the mind, and of well-governed passions; and from admiring the virtues of others in moral paintings, come to approve and imitate them himself. Therefore to cultivate a true and correct taste, must be both our interest and our duty, when the circumstances of our station give leisure and opportunity for it, and when the doing it is not inconsistent with our higher obligations or engagements to society and mankind.

It is best attained by reading the best books, where good sense has more the ascendant than learning, and which retain more to practice than to speculation; by studying the best models, *i. e.* those which profess to imitate nature most, and approach the nearest to it; and by conversing with men of the most refined taste, and the greatest experience in life.

As to the other intellectual goods, what a fund of entertainment must it be to investigate the truth and various relations of things; to trace the operations of nature to general laws; to explain by these its manifold phenomena: to understand that order by which the universe is upheld, and that economy by which it is governed; to be acquainted with the human mind, the connection, subor-

dinations, and uses of its powers, and to mark their energy in life! How agreeable to the ingenious inquirer, to observe the manifold relations and combinations of individual minds in society; to discern the causes why they flourish or decay; and from thence to ascend, through the vast scale of beings, to that General Mind which presides over all, and operates unseen in every system, and in every age, through the whole compass and progression of nature! Devoted to such entertainments as these, the contemplative have abandoned every other pleasure, and sequestered themselves from social intercourse; for these the busy have often preferred, to the hurry and din of life, the calm retreats of contemplation; for these, when once they came to taste them, even the gay and voluptuous have thrown up the lawless pursuits of sense and appetite, and acknowledged these mental enjoyments to be the most refined, and indeed the only luxury. Besides, by a just and large knowledge of nature, we recognize the perfections of its Author; and thus piety, and all those pious affections which depend on just sentiments of his character, are awakened and confirmed; and a thousand superstitious fears, that arise from partial views of his nature and works, will of course be excluded. An extensive prospect of human life, and of the periods and revolutions of human things, will conduce much to the giving a certain greatness of mind, and a noble contempt of those little competitions about power, honour, and wealth, which disturb and divide the bulk of mankind; and promote a calm endurance of those inconveniences and ills that are the common appendages of humanity. Add to all, that a just knowledge of human nature, and of those hinges upon which the business and fortunes of men turn, will prevent our thinking either too highly, or too meanly of our fellow-creatures; give no small scope to the exercise of friendship, confidence, and goodwill; and, at the same time, brace the mind with a proper caution and distrust, and give a greater mastery in the conduct of private as well as public life. Therefore, by cultivating our intellectual abilities, we shall best promote and secure our interest, and be qualified for acting our part in society with more honour to ourselves, as well as advantage to mankind. Consequently, to improve them to the utmost of our power is our duty; they are talents committed to us by the Almighty Head of society, and we are accountable to him for the use of them.

The intellectual virtues are best improved by accurate and impartial observation, extensive reading, and unconfined converse with men of all characters, especially with those who, to private study, have joined the widest acquaintance with the world and greatest practice in its affairs; but above all, by being much in the world, and having large dealings with mankind. Such opportunities contribute much to dislodge one of prejudices and a servile attachment to crude systems, to open one's views, and to give that experience on which the most useful knowledge is built, and from which the surest maxims for the conduct of life are deduced.

The highest goods which enter into the composition of human happiness are moral goods of the mind, directly and ultimately regarding ourselves; as command of the appetites and passions, prudence and caution, magnanimity, fortitude,

fortitude, humility, love of virtue, love of God, resignation, and the like. These sublime goods are, by way of eminence, goods recommended and enforced by the most intimate and awful sense and consciousness of our nature; goods that constitute the quintessence of happiness, that form and completion of soul which renders us agreeable and lovely in the sight of God; goods, in fine, which are the elements of all our future perfection and felicity.

Most of the other goods we have considered depend partly on ourselves, and partly on accidents which we can neither foresee nor prevent, and result from causes which we cannot influence or alter. They are such goods as we may possess to-day and lose to-morrow, and which require a felicity of constitution and talents to attain them in full vigour and perfection, and a felicity of conjunctures to secure the possession of them. Therefore, did our happiness depend altogether or chiefly on such transitory and precarious possessions, it were itself most precarious, and the highest folly to be anxious about it.—But though creatures, constituted as we are, cannot be indifferent about such goods, and must suffer in some degree, and consequently have our happiness incomplete without them, yet they weigh but little in the scale when compared with moral goods. By the benevolent constitution of our nature, these are placed within the sphere of our activity, so that no man can be destitute of them unless he is first wanting to himself. Some of the wisest and best of mankind have wanted most of the former goods, and all the external kind, and felt most of the opposite ills; yet, by possessing the latter, have declared they were happy, and to the conviction of the most impartial observers have appeared happy. The worst of men have been surrounded with every outward good and advantage of fortune, and have possessed great parts; yet, for want of moral rectitude, have been notoriously and exquisitely miserable. The exercise of virtue has supported its votaries, and made them exult in the midst of tortures almost intolerable; nay, how often has some false form or shadow of it sustained even the greatest villains and bigots under the same pressures! But no external goods, no goods of fortune, have been able to alleviate the agonies, or expel the fears of a guilty mind, conscious of the deserved hatred and reproach of mankind, and the just displeasure of almighty God.

As the present condition of human life is wonderfully chequered with good and ill; and as no height of station, no affluence of fortune, can absolutely insure the good or secure against the ill; it is evident, that a great part of the comfort and serenity of life must lie in having our minds duly affected with regard to both, *i. e.* rightly attuned to the loss of one and the sufferance of the other. For it is certain, that outward calamities derive their chief malignity and pressure from the inward dispositions with which we receive them. By managing these right, we may greatly abate that malignity and pressure, and consequently diminish the number and weaken the moment of the ills of life, if we should not have it in our power to obtain a large share of its goods. There are particularly three virtues which go to the forming this right temper towards ill, and which are of singular efficacy, if

not totally to remove, yet wonderfully to alleviate the calamities of life. These are fortitude, or patience, humility, and resignation.

Fortitude is that calm and steady habit of mind, which either moderates our fears, and enables us bravely to encounter the prospect of ill, or renders the mind serene and invincible under its immediate pressure. It lies equally distant from rashness and cowardice; and though it does not hinder us from feeling, yet prevents our complaining or shrinking under the stroke. It always includes a generous contempt of, or at least a noble superiority to, those precarious goods of which we can insure neither the possession nor continuance. The man therefore who possesses this virtue in this ample sense of it, stands upon an eminence, and sees human things below him; the tempest indeed may reach him, but he stands secure and collected against it upon the basis of conscious virtue, which the severest storms can seldom shake, and never overthrow.

Humility is another virtue of high rank and dignity, though often mistaken for proud mortals for meanness and pusillanimity. It is opposed to pride, which commonly includes in it a false or over-rated estimation of our own merit, an ascription of it to ourselves as its only and original cause, an undue comparison of ourselves with others, and, in consequence of that supposed superiority, an arrogant preference of ourselves, and a supercilious contempt of them. Humility, on the other hand, seems to denote that modest and ingenuous temper of mind, which arises from a just and equal estimate of our own advantages compared with those of others, and from a sense of our deriving all originally from the Author of our being. Its ordinary attendants are mildness, a gentle forbearance, and an easy unassuming humanity with regard to the imperfections and faults of others; virtues rare indeed, but of the fairest complexion, the proper offspring of so lovely a parent, the best ornaments of such imperfect creatures as we are, precious in the sight of God, and which sweetly allure the hearts of men.

Resignation is that mild and heroic temper of mind, which arises from a sense of an infinitely wise and good providence, and enables one to acquiesce with a cordial affection in its just appointments. This virtue has something very peculiar in its nature, and sublime in its efficacy. For it teaches us to bear ill, not only with patience, and as being unavoidable; but it transforms, as it were, ill into good, by leading us to consider it, and every thing that has the least appearance of ill, as a divine dispensation, a wise and benevolent temperament of things, subservient to universal good, and of course including that of every individual, especially of such as calmly stoop to it. In this light, the administration itself, nay, every act of it, becomes an object of affection; the evil disappears, or is converted into a balm which both heals and nourishes the mind. For, though the first unexpected access of ill may surprise the soul into grief; yet that grief, when the mind calmly reviews its object, changes into contentment, and is by degrees exalted into veneration and a divine composure. Our private will is lost in that of the Almighty, and our security against every real ill rests on the same bottom as the throne of Him who lives and reigns for ever.

Before we finish this section, it may be fit to observe, that as the Deity is the supreme and inexhausted source of good, on whom the happiness of the whole creation depends; as he is the highest object in nature, and the only object who is fully proportioned to the intellectual and moral powers of the mind, in whom they ultimately rest and find their most perfect exercise and completion; he is therefore termed the *chief good* of man *objectively* considered: And virtue, or the proportioned and vigorous exercise of the several powers and affections on their respective objects, as above described, is, in the schools, termed the *chief good* *formally* considered, or its *formal* idea, being the inward temper and native constitution of human happiness.

From the detail we have gone through, the following corollaries may be deduced.

1. It is evident that the happiness of such a progressive creature as man can never be at a stand, or continue a fixed invariable thing. His finite nature, let it rise ever so high, admits still higher degrees of improvement and perfection: and his progression in improvement, or virtue, always makes way for a progression in happiness. So that no possible point can be assigned in any period of his existence in which he is perfectly happy, that is, so happy as to exclude higher degrees of happiness. All his perfection is only comparative. 2. It appears that many things must conspire to complete the happiness of so various a creature as man, subject to so many wants, and susceptible of such different pleasures. 3. As his capacities of pleasure cannot be all gratified at the same time, and must often interfere with each other in such a precarious and fleeting state as human life, or be frequently disappointed, perfect happiness, *i. e.* the undisturbed enjoyment of the several pleasures of which we are capable, is unattainable in our present state. 4. That state is most to be sought after, in which the fewest competitions and disappointments can happen, which least of all impairs any sense of pleasure, and opens an inexhausted source of the most refined and lasting enjoyments. 5. That state which is attended with all those advantages is a state or course of virtue. 6. Therefore, a state of virtue, in which the moral goods of the mind are attained, is the happiest state.

DUTIES to SOCIETY.

Filial and Fraternal duty.

As we have followed the order of nature in tracing the history of man, and those duties which he owes to himself; it seems reasonable to take the same method with those he owes to society, which constitute the second class of his obligations:

His parents are among the earliest objects of his attention; he becomes soonest acquainted with them, reposes a peculiar confidence in them, and seems to regard them with a fond affection, the early prognostics of his future piety and gratitude. Thus does nature dictate the first lines of filial duty, even before a just sense of the connection is formed. But when the child is grown up, and has attained to such a degree of understanding as to comprehend the moral tie, and be sensible of the obligations

he is under to his parents; when he looks back on their tender and disinterested affection, their incessant cares and labours in nursing, educating and providing for him during that state in which he had neither prudence nor strength to care and provide for himself; he must be conscious that he owes to them these peculiar duties.

1. To reverence and honour them as the instruments of nature in introducing him to life, and to that state of comfort and happiness which he enjoys; and therefore to esteem and imitate their good qualities, to alleviate and bear with, and spread as much as possible a decent veil over their faults and weaknesses.

2. To be highly grateful to them for those favours which it can hardly ever be in his power fully to repay; to shew this gratitude by a strict attention to their wants, and a solicitous care to supply them; by a submissive deference to their authority and advice; by yielding to, rather than peevishly contending with their humours, as remembering how oft they have been persecuted by his; and in fine, by soothing their cares, lightening their sorrows, supporting the infirmities of age, and making the remainder of their life as comfortable and joyful as possible.

As his brethren and sisters are the next with whom the creature forms a social and moral connection, to them he owes a fraternal regard; and with them ought he to enter into a strict league of friendship, mutual sympathy, advice, assistance, and a generous intercourse of kind offices, remembering their relation to common parents, and that brotherhood of nature which unites them into a closer community of interest and affection.

Concerning Marriage.

WHEN man arrives to a certain age, he becomes sensible of a peculiar sympathy and tenderness towards the other sex; the charms of beauty engage his attention, and call forth new and softer dispositions than he has yet felt. The many amiable qualities exhibited by a fair outside, or by the mild allurements of female manners, or which the prejudiced spectator without much reasoning supposes those to include, with several other circumstances, point his view and affection to a particular object, and of course contract that general rambling regard, which was lost and useless among the undistinguished croud, into a peculiar and permanent attachment to one woman, which ordinarily terminates in the most important, venerable, and delightful connection in life.

The state of the brute-creation is very different from that of human creatures. The former are clothed and generally armed by their structure, easily find what is necessary to their subsistence, and soon attain their vigour and maturity; so that they need the care and aid of their parents but for a short while; and therefore we see that nature has assigned to them vagrant and transient amours. The connection being purely natural, and formed merely for propagating and rearing their offspring; no sooner is that end answered, than the connection dissolves of course. But the human race are of a more tender and defenceless constitution; their infancy and non-age continue longer; they advance slowly to strength of body, and maturity of reason; they need constant attention, and a long series of

cares and labours to train them up to decency, virtue, and the various arts of life. Nature has, therefore, provided them with the most affectionate and anxious tutors, to aid their weakness, to supply their wants, and to accomplish them in those necessary arts;—even their own parents, on whom she has devolved this mighty charge, rendered agreeable by the most alluring and powerful of all ties, parental affection. But unless both concur in this grateful task, and continue their joint labours, till they have reared up and planted out their young colony, it must become a prey to every rude invader, and the purpose of nature in the original union of the human pair be defeated. Therefore our structure as well as condition is an evident indication, that the human sexes are destined for a more intimate, for a moral and lasting union. It appears likewise, that the principal end of marriage is not to propagate and nurse up an offspring, but to educate and form minds for the great duties and extensive destinations of life. Society must be supplied from this original nursery with useful members, and its fairest ornaments and supports.

The mind is apt to be dissipated in its views, and acts of friendship and humanity; unless the former be directed to a particular object, and the latter employed in a particular province. When men once indulge to this dissipation, there is no stopping their career; they grow insensible to moral attractions, and, by obstrucing or impairing the decent and regular exercise of the tender and generous feelings of the human heart, they in time become unqualified for, or averse to, the forming a moral union of souls, which is the cement of society, and the source of the purest domestic joys. Whereas a rational unperverted love, and its fair companion marriage, collect a man's views, guide his heart to its proper object, and by confining his affection to that object do really enlarge its influence and use. Besides, it is but too evident from the conduct of mankind, that the common ties of humanity are too feeble to engage and interst the passions of the generality in the affairs of society. The connections of neighbourhood, acquaintance, and general intercourse, are too wide a field of action for many; and those of a public or community are so for more, and in which they either care not or know not how to exert themselves. Therefore nature, ever wise and benevolent, by implanting that strong sympathy which reigns between the individuals of each sex, and by urging them to form a particular moral connection, the spring of many domestic endearments, has measured out to each pair a particular sphere of action, proportioned to their views, and adapted to their respective capacities. Besides, by intersting them deeply in the concerns of their own little circle, she has connected them more closely with society, which is composed of particular families, and bound them down to their good behaviour in that particular community to which they belong. This moral connection is marriage, and this sphere of action is a family.

Of the conjugal alliance the following are the natural laws. 1. Mutual fidelity to the marriage-bed. Disloyalty defeats the very end of marriage; dissolves the natural cement of the relation; weakens the moral

tie, the chief strength of which lies in the reciprocation of affection; and, by making the offspring uncertain, diminishes the care and attachment necessary to their education.

2. A conspiracy of counsels and endeavours to promote the common interest of the family, and to educate their common offspring. In order to observe these laws, it is necessary to cultivate, both before and during the married state, the strictest decency and chastity of manners, and a just sense of what becomes their respective characters.

3. The union must be inviolable and for life. The nature of friendship, and particularly of this species of it, the education of their offspring, and the order of society, and of successions which would otherwise be extremely perplexed, do all seem to require it. To preserve this union, and render the matrimonial state more harmonious and comfortable, a mutual esteem and tenderness, a mutual deference and forbearance, a communication of advice, and assistance and authority, are absolutely necessary. If either party keep within their proper departments, there need be no disputes about power or superiority, and there will be none. They have no opposite, no separate interests; and therefore there can be no just ground for opposition of conduct.

From this detail, and the present state of things, in which there is pretty near a parity of numbers of both sexes, it is evident, that polygamy is an unnatural state: and though it should be granted to be more fruitful of children, which however it is not found to be; yet it is by no means so fit for rearing minds; which seems to be as much, if not more, the intention of nature, than the propagation of bodies.

Of Parental Duty.

THE connection of parents with their children is a natural consequence of the matrimonial connection, and the duties which they owe them result as naturally from that connection. The feeble state of children, subject to so many wants and dangers, requires their incessant care and attention; their ignorant and uncultivated minds demand their continual instruction and culture. Had human creatures come into the world with the full strength of men, and the weakness of reason and vehemence of passions which prevail in children, they would have been too strong or too stubborn to have submitted to the government and instruction of their parents. But, as they were designed for a progression in knowledge and virtue, it was proper that the growth of their bodies should keep pace with that of their minds, lest the purposes of that progression should have been defeated. Among other admirable purposes which this gradual expansion of their outward as well as inward structure serves, this is one, that it affords ample scope to the exercise of many tender and generous affections, which fill up the domestic life with a beautiful variety of duties and enjoyments; and are of course a noble discipline for the heart, and an hardy kind of education for the more honourable and important duties of public life.

The above mentioned weak and ignorant state of children, seems plainly to invest their parents with such authority

thority and power as is necessary to their support, protection, and education: but that authority and power can be continued to extend no farther than is necessary to answer those ends, and to last no longer than that weakness and ignorance continue; wherefore, the foundation or reason of the authority and power ceasing, they cease of course. Whatever power or authority, then, it may be necessary or lawful for parents to exercise during the nourage of their children, to assume or usurp the same when they have attained the maturity or full exercise of their strength and reason, would be tyrannical and unjust. From hence it is evident, that parents have no right to punish the persons of their children more severely than the nature of their wardship requires; much less to invade their lives, to encroach upon their liberty, or transfer them as their property to any matter whatsoever.

The first class of duties which parents owe their children respect their natural life; and these comprehend protection, nurture, provision, introducing them into the world in a manner suitable to their rank and fortune, and the like.

The second order of duties regards the intellectual and moral life of their children, or their education in such arts and accomplishments as are necessary to qualify them for performing the duties they owe to themselves and to others. As this was found to be the principal design of the matrimonial alliance, so the fulfilling that design is the most important and dignified of all the parental duties. In order therefore to fit the child for acting his part wisely and worthily, as a man, as a citizen, and a creature of God, both parents ought to combine their joint wisdom, authority, and power, and each apart to employ those talents which are the peculiar excellency and ornament of their respective sex. The father ought to lay out and superintend their education; the mother to execute and manage the detail of which she is capable. The former should direct the manly exertion of the intellectual and moral powers of his child. His imagination, and the manner of those exertions, are the peculiar province of the latter. The former should advise, protect, command, and by his experience, masculine vigour, and that superior authority which is commonly ascribed to his sex, brace and strengthen his pupil for active life, for gravity, integrity, and firmness in suffering. The business of the latter is to bend and soften her male pupil, by the charms of her conversation, and the softness and decency of her manners, for social life, for politeness of taste, and the elegant decors of and enjoyments of humanity; and to improve and refine the tenderness and modesty of her female pupil, and form her to all those mild domestic virtues, which are the peculiar characteristics and ornaments of her sex.

To conduct the opening minds of their sweet charge through the several periods of their progress; to assist them in each period in throwing out the latent seeds of reason and ingenuity, and in gaining fresh accessions of light and virtue; and at length, with all these advantages, to produce the young adventurers upon the great theatre of human life, to play their several parts in the sight of their friends, of society, and mankind.

Herile and Servile Duty.

IN the natural course of human affairs it must necessarily happen, that some of mankind will live in plenty and opulence, and others be reduced to a state of indigence and poverty. The former need the labours of the latter, and the latter the provision and support of the former. This mutual necessity is the foundation of that connection, whether we call it moral or civil, which subsists between masters and servants. He who feeds another has a right to some equivalent, the labour of him whom he maintains, and the fruits of it. And he who labours for another has a right to expect that he should support him. But as the labours of a man of ordinary strength are certainly of greater value than mere food and clothing; because they would actually produce more, even the maintenance of a family, were the labourer to employ them in his own behalf; therefore he has an undoubted right to rate and dispose of his service for certain wages above mere maintenance; and if he has incautiously disposed of it for the latter only, yet the contract being of the onerous kind, he may equitably claim a supply of that deficiency. If the service be specified, the servant is bound to that only; if not, then he is to be construed as bound only to such services as are consistent with the laws of justice and humanity. By the voluntary servitude to which he subjects himself, he forfeits no rights but such as are necessarily included in that servitude, and is obnoxious to no punishment but such as a voluntary failure in the service may be supposed reasonably to require. The offspring of such servants have a right to that liberty which neither they nor their parents have forfeited.

As to those who, because of some heinous offence, or for some notorious damage, for which they cannot otherwise compensate, are condemned to perpetual service; they do not, on that account, forfeit all the rights of men; but those, the loss of which is necessary to secure society against the like offences for the future, or to repair the damage they have done.

With regard to captives taken in war, it is barbarous and inhuman to make perpetual slaves of them, unless some peculiar and aggravated circumstances of guilt have attended their hostility. The bulk of the subjects of any government engaged in war, may be fairly esteemed innocent enemies; and therefore they have a right to that clemency which is consistent with the common safety of mankind, and the particular security of that society against which they are engaged. Though ordinary captives have a grant of their lives; yet to pay their liberty as an equivalent, is much too high a price. There are other ways of acknowledging or returning the favour, than by surrendering what is far dearer than life itself. To those who, under pretext of the necessities of commerce, drive the unnatural trade of bargaining for human flesh, and consigning their innocent but unfortunate fellow-creatures to eternal servitude and misery, we may address the words of a fine writer; "Let avarice defend it as it will, there is an honest reluctance in humanity against buying and selling and regarding those of our own species as our wealth and possessions."

Social Duties of the private Kind.

HITHERTO we have considered only the domestic economical duties, because these are first in the progress of nature. But as man passes beyond the little circle of a family, he forms connections with relations, friends, neighbours, and others; from whence results a new train of duties of the more private social kind, as friendship, chastity, courtesy, good-neighbourhood, charity, forgiveness, hospitality.

Man is admirably formed for particular social attachments and duties. There is a peculiar and strong propensity in his nature to be affected with the sentiments and dispositions of others. Men, like certain musical instruments, are set to each other, so that the vibrations or notes excited in one raise correspondent notes and vibrations in the others. The impulses of pleasure or pain, joy or sorrow, made on one mind, are, by an instantaneous sympathy of nature, communicated in some degree to all; especially when hearts are in unison of kindness; the joy that vibrates in one, communicates to the other also. We may add, that though joy thus imparted swells the harmony; yet grief vibrated to the heart of a friend, and rebounding from thence in sympathetic notes, melts, as it were, and almost dies away. All the passions, but especially those of the social kind, are contagious; and when the passions of one man mingle with those of another, they increase and multiply prodigiously. There is a most moving eloquence in the human countenance, air, voice, and gesture, wonderfully expressive of the most latent feelings and passions of the soul, which darts them, like a subtle flame, into the hearts of others, and raises correspondent feelings there: friendship, love, good humour, joy, spread through every feature, and particularly shoot from the eyes their softer and fiercer fires with an irresistible energy. And in like manner, the opposite passions of hatred, enmity, ill humour, melancholy, diffuse a sultry and saddening air over the face, and, flashing from eye to eye, kindle a train of similar passions. By these and other admirable pieces of machinery, men are formed for society and the delightful interchange of friendly sentiment and duties; to increase the happiness of others by participation, and their own by rebound; and to diminish, by dividing, the common stock of their misery.

The first emanations of the social principle beyond the bounds of a family, lead us to form a nearer conjunction of friendship or goodwill with those who are anywise connected with us by blood or domestic alliance. To them our affection does, commonly, exert itself in a greater or less degree, according to the nearness or distance of the relation. And this proportion is admirably suited to the extent of our powers and the indigence of our state; for it is only within those lesser circles of consanguinity or alliance, that the generality of mankind are able to display their abilities or benevolence, and consequently to uphold their connection with society and suberviency to a public interest. Therefore it is our duty to regard these closer connections as the next department to that of a family, in which nature has marked out for us a sphere of activity and usefulness; and to cultivate the

kind affections which are the cement of those endearing alliances.

Frequently, the view of distinguishing moral qualities in some of our acquaintance may give birth to that more noble connection we call friendship, which is far superior to the alliances of consanguinity. For these are of a superficial, and often of a transitory nature; of which, as they hold more of instinct than of reason, we cannot give such a rational account. But friendship derives all its strength and beauty, and the only existence which is durable, from the qualities of the heart, or from virtuous and lovely dispositions. Therefore friendship may be described to be, "The union of two souls, by means of virtue, the common object and cement of their mutual affection." Without virtue, or the supposition of it, friendship is only a mercenary league, an alliance of interest, which must dissolve of course when that interest decays or subsists no longer. It is not so much any particular passion, as a composition of some of the noblest feelings and passions of the mind. Good sense, a just taste and love of virtue, a thorough candor and benignity of heart, or what we usually call a good temper, and a generous sympathy of sentiments and affections, are the necessary ingredients of this virtuous connection. When it is grafted on esteem, strengthened by habit, and mellowed by time, it yields infinite pleasure ever new and ever growing, is a noble support amidst the various trials and vicissitudes of life, and an high seasoning to most of our other enjoyments. To form and cultivate virtuous friendship must be very improving to the temper; as its principal object is virtue, set off with all the allurements of countenance, air, and manners, shining forth in the native graces of manly honest sentiments and affections, and rendered visible as it were to the friendly spectator in a conduct unaffectedly great and good; and as its principal exercises are the very energies of virtue, or its effects and emanations. So that, where-ever this amiable attachment prevails, it will exalt our admiration and attachment to virtue, and, unless impeded in its course by unnatural prejudices, run out into a friendship to the human race. For as no one can merit, and none ought to usurp, the sacred name of friend, who hates mankind; so, who-ever truly loves them, possesses the most essential quality of a true friend.

The duties of friendship are, a mutual esteem of each other, unbribed by interest, and independent of it; a generous confidence, as far distant from suspicion as from reserve; an inviolable harmony of sentiments and dispositions, of designs and interests; a fidelity unshaken by the changes of fortune; a constancy unalterable by distance of time or place; a resignation of one's personal interests to those of one's friend; and a reciprocal, unenvious, unreserved exchange of kind offices.—But amidst all the exertions of this moral connection, humane and generous as it is, we must remember that it operates within a narrow sphere, and its immediate operations respect only the individual; and therefore particular impulses must still be subordinate to a more public interest, or be always directed and controuled by the more extensive connections of our nature.

When our friendship terminates on any of the other

sex, in whom beauty or agreeableness of person and external gracefulness of manners conspire to express and heighten the moral charm of a tender honest heart, and sweet, ingenuous, modest temper, lighted up by good sense, it generally grows into a more soft and endearing attachment. When this attachment is improved by a growing acquaintance with the worth of its object, is conducted by discretion, and issues at length, as it ought to do, in the moral connection of marriage, it becomes the source of many amiable duties, of a communication of passions and interests, of the most refined decencies, and of a thousand nameless deep-felt joys of reciprocal tenderness and love, flowing from every look, word, and action. Here friendship acts with double energy, and the natural conspires with the moral charm to strengthen and secure the love of virtue. As the delicate nature of female honour and decorum, and the inexpressible grace of a chaste and modest behaviour, are the surest and indeed the only means of kindling at first, and ever after of keeping alive this tender and elegant flame, and of accomplishing the excellent ends designed by it; to attempt by fraud to violate one, or, under pretence of passion, fully and corrupt the other, and, by so doing, to expose the too often credulous and unguarded object, with a wanton cruelty, to the hatred of her own sex, and the scorn of ours, and to the lowest infamy of both, is a conduct not only base and criminal, but inconsistent with that truly rational and refined enjoyment, the spirit and quintessence of which is derived from the balmy and sacred charms of virtue kept untainted, and therefore ever alluring to the lover's heart.

Courtesy, good-neighbourhood, affability, and the like duties which are founded on our private social connections, are no less necessary and obligatory to creatures united in society, and supporting and supported by each other in a chain of mutual want and dependence. They do not consist in a smooth address, an artificial or obsequious air, fawning adulation, or a polite servility of manners; but in a just and modest sense of our own dignity and that of others, and of the reverence due to mankind, especially to those who hold the higher links of the social chain; in a discreet and manly accommodation of ourselves to the foibles and humours of others; in a strict observance of the rules of decorum and civility; but above all in a frank obliging carriage, and generous interchange of good deeds rather than words. Such a conduct is of great use and advantage, as it is an excellent security against injury, and the best claim and recommendation to the esteem, civility, and universal respect of mankind. This inferior order of virtues unites the particular members of society more closely, and form the lesser pillars of the civil fabric; which, in many instances, supply the unavoidable defects of laws, and maintain the harmony and decorum of social intercourse, where the more important and essential lines of virtue are wanting.

Charity and forgiveness are truly amiable and useful duties of the social kind. There is a twofold distinction of rights commonly taken notice of by moral writers, *viz.* perfect and imperfect. To fulfil the former, is necessary to the being and support of society; to fulfil the latter, is a duty equally sacred and obligatory, and tends

to the improvement and prosperity of society: but as the violation of them is not equally prejudicial to the public good, the fulfilling them is not subjected to the cognizance of laws, but left to the candor, humanity, and gratitude of individuals. And by this means ample scope is given to exercise all the generosity, and display the genuine merit and lustre of virtue. Thus the wants and misfortunes of others call for our charitable assistance and seasonable supplies: and the good man, unconstrained by law, and uncontrolled by human authority, will cheerfully acknowledge and generously satisfy this mournful and moving claim; a claim supported by the sanction of heaven, of whose bounties he is honoured to be the grateful trustee. If his own perfect rights are invaded by the injustice of others, he will not therefore reject their imperfect right to pity and forgiveness, unless his grant of these should be inconsistent with the more extensive rights of society or the public good. In that case he will have recourse to public justice and the laws; and even then he will prosecute the injury with no unnecessary severity, but rather with mildness and humanity. When the injury is merely personal, and of such a nature as to admit of alleviations, and the forgiveness of which would be attended with no worse consequences, especially of a public kind, the good man will generously forgive his offending brother. And it is his duty to do so, and not to take private revenge, or retaliate evil for evil. For though resentment of injury is a natural passion, and implanted, as was observed above, for wise and good ends; yet, considering the manifold partialities which most men have for themselves, was every one to act as judge in his own cause, and to execute the sentence dictated by his own resentment, it is but too evident that mankind would pass all bounds in their fury, and the last sufferer be provoked in his turn to make full reprisals. So that evil, thus encountering with evil, would produce one continued series of violence and misery, and render society intolerable, if not impracticable. Therefore, where the security of the individual, or good of the public, does not require a proportionable retaliation, it is agreeable to the general law of benevolence, and to the particular end of the passion (which is to prevent injury, and the misery occasioned by it) to forgive personal injuries, or not to return evil for evil. This duty is one of the noble refinements which Christianity has made upon the general maxims and practice of mankind, and enforced with a peculiar strength and beauty by fictions no less alluring than awful. And indeed the practice of it is generally its own reward; by expelling from the mind the most dreadful intruders upon its repose, those rancorous passions which are begot and nursed by resentment; and by disarming and even subduing every enemy one has, except such as have nothing left of men but the outward form.

The most enlarged and humane connection of the private kind, seems to be the hospitable alliance from which flow the amiable and disinterested duties we owe to strangers. If the exercise of passions of the most private and instinctive kind is beheld with moral approbation and delight, how lovely and venerable must those appear, which result from a calm philanthropy, are founded in the common rights and connections of society, and embrace men,

not of a particular sect, party, or nation, but all in general without distinction, and without any of the little partialities of self-love!

Social Duties of the COMMERCIAL Kind.

THE next order of connections are those which arise from the wants and weakness of mankind, and from the various circumstances in which their different situations place them. These we may call *commercial connections*; and the duties which result from them *commercial duties*, as justice, fair-dealing, sincerity, fidelity to compacts, and the like.

Though nature is perfect in all her works, yet she has observed a manifest and eminent distinction among them. To all such as lie beyond the reach of human skill and power, and are properly of her own department, she has given the finishing hand. These man may design after and imitate; but he can neither rival them, nor add to their beauty or perfection: such are the forms and structure of vegetables, animals, and many of their productions. There are others of her works which she has of design left unfinished, as it were, in order to exercise the ingenuity and power of man. She has presented to him a rich profusion of materials of every kind for his convenience and use; but they are rude and unpolished, or not to be come at without art and labour. These therefore he must apply, in order to adapt them to his use, and to enjoy them in perfection. Thus nature has given him an infinite variety of herbs, grain, fossils, minerals, wood, water, earth, and a thousand other crude materials to supply his numerous wants. But he must sow, plant, dig, refine, polish, build, and, in short, manufacture the various produce of nature, in order to obtain even the necessities, and much more the conveniences and elegancies of life. These, then, are the price of his labour and industry; and, without that, nature will sell him nothing. But as the wants of mankind are many, and the single strength of individuals small, they could hardly find the necessities, and much less the conveniences of life, without uniting their ingenuity and strength in acquiring these, and without a mutual intercourse of good offices. Some men are better formed for some kinds of ingenuity and labour, and others for other kinds; and different soils and climates are enriched with different productions; so that men, by exchanging the produce of their respective labours, and supplying the wants of one country with the superfluities of another, do, in effect, diminish the labours of each, and increase the abundance of all. This is the foundation of all commerce, or exchange of commodities and goods one with another; in order to facilitate which, men have contrived different species of coin or money, as a common standard by which to estimate the comparative values of their respective goods. But, to render commerce sure and effectual, justice, fair-dealing, sincerity, and fidelity to compacts are absolutely necessary.

Justice, or fair dealing, or, in other words, a disposition to treat others as we would be treated by them, is a virtue of the first importance, and inseparable from the virtuous character. It is the cement of society, or that pervading spirit which connects its members, inspires its

various relations, and maintains the order and subordination of each part to the whole. Without it, society would become a den of thieves and banditti, hating and hated, devouring and devoured, by one another.

Sincerity or veracity in our words and actions is another virtue or duty of great importance to society, being one of the great bands of mutual intercourse, and the foundation of mutual trust. Without it, society would be the dominion of mistrust, jealousy and fraud, and conversation a traffick of lies and dissimulation. It includes in it a conformity of our words with our sentiments, a correspondence between our actions and dispositions, a strict regard to truth, and an irreconcilable abhorrence of falsehood. It does not indeed require that we expose our sentiments indiscreetly, or tell all the truth in every case; but certainly it does not and cannot admit the least violation of truth, or contradiction to our sentiments. For if these bounds are once passed, no possible limit can be assigned where the violation shall stop; and no pretence of private or public good can possibly counterbalance the ill consequences of such a violation.

Fidelity to promises, compacts and engagements, is likewise a duty of such importance to the security of commerce and interchange of benevolence among mankind, that society would soon grow intolerable without the strict observance of it. Hobbes, and others who follow the same track, have taken a wonderful deal of pains to puzzle this subject, and to make all the virtues of this sort merely artificial, and not at all obligatory, antecedent to human conventions. No doubt, compacts suppose people who make them, and promises suppose persons to whom they are made; and therefore both suppose some society more or less between those who enter into these mutual engagements. But is not a compact or promise binding, till men have agreed that they shall be binding? Or are they only binding because it is our interest to be bound by them, or to fulfill them? Do not we highly approve the man who fulfils them, even though they should prove to be against his interest? And do not we condemn him as a knave, who violates them on that account? A promise is a voluntary declaration, by words, or by an action equally significant, of our resolution to do something in behalf of another, or for his service. When a promise is made, the person who makes it is by all supposed under an obligation to perform it; and he to whom it is made may demand the performance as his right. That perception of obligation is a simple idea, and is on the same footing as our other moral perceptions, which may be described by instances, but cannot be defined. Whether we have a perception of such obligation quite distinct from the interest, either public or private, that may accompany the fulfilment of it, must be referred to the conscience of every individual. And, whether the mere sense of that obligation, apart from its concomitants, is not a sufficient inducement or motive to keep one's promise, without having recourse to any selfish principle of our nature, must be likewise appealed to the conscience of every honest man. Fair dealing and fidelity to compacts require that we take no advantage of the ignorance, passion, or incapacity of others, from whatever cause that incapacity arises;—that we be explicit and candid in making bargains, just and faithful.

faithful in fulfilling our part of them. And if the other party violates his engagements, redress is to be sought from the laws, or from those who are intrusted with the execution of them. In fine, the commercial virtues and duties require that we not only do not invade, but maintain the rights of others :—that we be fair and impartial in transferring, bartering, or exchanging property, whether in goods or service ;—and be inviolably faithful to our word and our engagements, where the matter of them is not criminal, and where they are not extorted by force.

Social Duties of the Political Kind.

WE are now arrived at the last and highest order of duties respecting society, which result from the exercise of the most generous and heroic affections, and are founded on our most elegant connections.

The social principle in man is of such an expansive nature, that it cannot be confined within the circuit of a family, of friends, or a neighbourhood ; it spreads into wider systems, and draws men into larger confederacies, communities, and commonwealths.—It is in these only that the higher powers of our nature attain the highest improvement and perfection of which they are capable. These principles hardly find objects in the solitary state of nature. There the principle of action rises no higher at farthest than natural affection towards one's offspring. There personal or family wants entirely engross the creature's attention and labour, and allow no leisure, or, if they did, no exercise for views and affections of a more enlarged kind. In solitude all are employed in the same way ; in providing for the animal life. And even after their utmost labour and care, single and unaided by the industry of others, they find but a sorry supply of their wants, and a feeble precarious security against dangers from wild beasts, from inclement skies and seasons, from the mistakes or petulant passions of their fellow-creatures, from their preference of themselves to their neighbours, and from all the little exorbitances of self-love. But in society, the mutual aids which men give and receive shorten the labours of each, and the combined strength and reason of individuals give security and protection to the whole body. There is both a variety and subordination of genius among mankind. Some are formed to lead and direct others ; to contrive plans of happiness for individuals, and of government for communities ; to take in a public interest ; to invent laws and arts, and superintend their execution ; and, in short, to refine and civilize human life. Others, who have not such good heads, may have as honest hearts, a truly public spirit, love of liberty, hatred of corruption and tyranny, a generous submission to laws, order, and public institutions, and an extensive philanthropy. And others, who have none of those capacities either of heart, or head, may be well formed for manual exercises and bodily labour. The former of these principles have no scope in solitude, where a man's thoughts and concerns do all either center in himself, or extend no farther than a family ; into which little circle all the duty and virtue of the solitary mortal is crowded. But society finds proper objects and exercises for every genius, and the noblest objects and exercises for the noblest geniuses,

and for the highest principles in the human constitution : particularly for that warmest and most divine passion, which God hath kindled in our bosoms, the inclination of doing good, and reverencing our nature ; which may find here both employment, and the most exquisite satisfaction. In society a man has not only more leisure, but better opportunities of applying his talents with much greater perfection and success, especially as he is furnished with the joint advice and assistance of his fellow creatures, who are now more closely united one with the other, and sustain a common relation to the same moral system, or community. This then is an object proportioned to his most enlarged social affections, and in serving it he finds scope for the exercise and refinement of his highest intellectual and moral powers. Therefore society, or a state of civil government, rests on these two principal pillars : “ that in it we find security against those evils which are unavoidable in solitude ; and obtain those goods, some of which cannot be obtained at all, and others not so well, in that state, where men depend solely on their individual sagacity and industry.”

From this short detail it appears that man is a social creature, and formed for a social state ; and that society, being adapted to the higher principles and destinations of his nature, must, of necessity, be his natural state.

The duties suited to that state, and resulting from those principles and destinations, or, in other words, from our social passions and social connections, or relation to a public system, are love of our country, resignation and obedience to the laws, public spirit, love of liberty, sacrifice of life and all to the public, and the like.

Love of our country is one of the noblest passions that can warm and animate the human breast. It includes all the limited and particular affections to our parents, children, friends, neighbours, fellow-citizens, countrymen. It ought to direct and limit their more confined and partial actions within their proper and natural bounds, and never let them encroach on those sacred and first regards we owe to the great public to which we belong. Were we solitary creatures, detached from the rest of mankind, and without any capacity of comprehending a public interest, or without affections leading us to desire and pursue it, it would not be our duty to mind it, nor criminal to neglect it. But, as we are parts of the public system, and are not only capable of taking in large views of its interests, but by the strongest affections connected with it, and prompted to take a share of its concerns, we are under the most sacred ties to prosecute its security and welfare with the utmost ardor, especially in times of public trial. This love of our country does not import an attachment to any particular soil, climate, or spot of earth, where perhaps we first drew our breath, though those natural ideas are often associated with the moral ones, and, like external signs or symbols, help to ascertain and bind them ; but it imports an affection to that moral system, or community, which is governed by the same laws and magistrates, and whose several parts are variously connected one with the other, and all united upon the bottom of a common interest. Perhaps indeed every member of the community cannot comprehend so large an object, especially if it extends through large provinces,

provinces, and over vast tracts of land; and still less can he form such an idea, if there is no public, *i. e.* if all are subjected to the caprice and unlimited will of one man: but the preference the generality shew to their native country, the concern and longing after it which they express when they have been long absent from it, the labours they undertake and sufferings they endure to save or serve it, and the peculiar attachment they have to their countrymen, evidently demonstrate that the passion is natural, and never fails to exert itself, when it is fairly disengaged from foreign clogs, and is directed to its proper object. Where-ever it prevails in its genuine vigour and extent, it swallows up all fordid and selfish regards; it conquers the love of ease, power, pleasure and wealth; nay, when the amiable partialities of friendship, gratitude, private affection, or regard to a family come in competition with it, it will teach us bravely to sacrifice all, in order to maintain the rights and promote or defend the honour and happiness of our country.

Resignation and obedience to the laws and orders of the society to which we belong, are political duties necessary to its very being and security, without which it must soon degenerate into a state of licence and anarchy. The welfare, nay, the nature of civil society, requires that there should be a subordination of orders or diversity of ranks and conditions in it;—that certain men, or orders of men, be appointed to superintend and manage such affairs as concern the public safety and happiness;—that all have their particular provinces assigned them;—that such a subordination be settled among them, as none of them may interfere with another;—and finally, that certain rules or common measures of action be agreed on, by which each is to discharge his respective duty to govern or be governed and all may concur in securing the order and promoting the felicity of the whole political body. Those rules of action are the laws of the community; and those different orders are the several officers, or magistrates, appointed by the public to explain them, and superintend or assist in their execution. In consequence of this settlement of things, it is the duty of each individual to obey the laws enacted, to submit to the executors of them with all due deference and homage according to their respective ranks and dignity, as to the keepers of the public peace, and the guardians of public liberty; to maintain his own rank, and perform the functions of his own station with diligence, fidelity, and incorruption. The superiority of the higher orders, or the authority with which the state has invested them, entitle them, especially if they employ their authority well, to the obedience and submission of the lower, and to a proportionable honour and respect from all. The subordination of the lower ranks claims protection, defence, and security from the higher. And the laws, being superior to all, require the obedience and submission of all; being the last resort, beyond which there is no decision or appeal.

Public spirit, heroic zeal, love of liberty, and the other political duties, do, above all others, recommend those who practise them to the admiration and homage of mankind; because, as they are the offspring of the noblest minds, so are they the parents of the greatest blessings to society. Yet, exalted as they are, it is only in equal

and free governments where they can be exercised and have their due effect: for there only does a true public prevail, and there only is the public good made the standard of the civil constitution. As the end of society is the common interest and welfare of the people associated, this end must of necessity be the supreme law or common standard by which the particular rules of action of the several members of the society towards each other are to be regulated. But a common interest can be no other than that which is the result of the common reason, or common feelings of all. Private men, or a particular order of men, have interests and feelings peculiar to themselves, and of which they may be good judges: but these may be separate from, and often contrary to the interests and feelings of the rest of the society; and therefore they can have no right to make, much less to impose, laws on their fellow-citizens, inconsistent with, or opposite to, those interests and those feelings. Therefore a society, a government, a real public, truly worthy the name; and not a confederacy of banditti, a clan of lawless savages, or a band of slaves under the whip of a master; must be such a one as consists of freemen, choosing or consenting to laws themselves, or, since it often happens that they cannot assemble and act in a collective body, delegating a sufficient number of representatives, *i. e.* such a number as shall most fully comprehend, and most equally represent, their common feelings and common interests, to digest and vote laws for the conduct and controul of the whole body the most agreeable to those common feelings and common interests.

A society thus constituted by common reason, and formed on the plan of a common interest, becomes immediately an object of public attention, public veneration, public obedience, a public and inviolable attachment, which ought neither to be seduced by bribes, nor awed by terrors; an object, in fine, of all those extensive and important duties which arise from so glorious a confederacy. To watch over such a system; to contribute all he can to promote its good by his reason, his ingenuity, his strength, and every other ability, whether natural or acquired; to resist, and to the utmost of his power defeat, every encroachment upon it, whether carried on by secret corruption, or open violence; and to sacrifice his ease, his wealth, his power, nay life itself, and, what is dearer still, his family and friends, to defend or save it; is the duty, the honour, the interest, and the happiness of every citizen; it will make him venerable and beloved while he lives, be lamented and honoured if he falls in so glorious a cause, and transmit his name with immortal renown to the latest posterity.

As the people are the fountain of power and authority, the original seat of majesty, the authors of laws, and the creators of officers to execute them; if they shall find the power they have conferred abused by their trustees, their majesty violated by tyranny or by usurpation, their authority prostituted to support violence or screen corruption, the laws grown pernicious through accidents unforeseen or unavoidable, or rendered ineffectual thro' the infidelity and corruption of the executors of them; then it is their right, and what is their right is their du-

ty, to resume that delegated power, and call their trustees to an account; to resist the usurpation, and extirpate the tyranny; to restore their sullied majesty and prostituted authority; to suspend, alter, or abrogate those laws, and punish their unfaithful and corrupt officers. Nor is it the duty only of the united body, but every member of it ought, according to his respective rank, power, and weight in the community, to concur in advancing and supporting those glorious designs.

Duty to God.

Of all the relations which the human mind sustains, that which subsists between the Creator and his creatures, the Supreme Lawgiver and his subjects, is the highest and the best. This relation arises from the nature of a creature in general, and the constitution of the human mind in particular; the noblest powers and affections of which point to an Universal Mind, and would be imperfect and abortive without such a direction. How lame then must that system of morals be, which leaves a Deity out of the question! How disconsolate, and how destitute of its firmest support!

It does not appear, from any true history or experience of the mind's progress, that any man, by any formal deduction of his discursive powers, ever reasoned himself into the belief of a God. Whether such a belief is only some natural anticipation of soul; or is derived from father to son, and from one man to another, in the way of tradition; or is suggested to us in consequence of an immutable law of our nature, on beholding the august aspect and beautiful order of the universe; we will not pretend to determine. What seems most agreeable to experience is, that a sense of its beauty and grandeur, and the admirable fitness of one thing to another in its vast apparatus, leads the mind necessarily and unavoidably to a perception of design, or of a designing cause, the origin of all, by a progress as simple and natural as that by which a beautiful picture or a fine building suggests to us the idea of an excellent artist. For it seems to hold universally true, that where-ever we discern a tendency or co-operation of things towards a certain end, or producing a common effect; there, by a necessary law of association, we apprehend design, a designing energy or cause: *See METAPHYSICS.* As we conceive this Being or First Cause before all, above all, and greater than all, we naturally, and without reasoning, ascribe to him every kind of perfection, wisdom, power, and goodness without bounds, existing through all time, and pervading all space. We apply to him those glorious epithets of our Creator, Preserver, Benefactor, the Supreme Lord and Law-giver of the whole society of rational intelligent creatures.—Not only the imperfections and wants of our being and condition, but some of the noblest instincts and affections of our minds, connect us with this great and universal nature. The mind, in its progress from object to object, from one character and prospect of beauty to another, finds some blemish or deficiency in each, and soon exhausts or grows weary and dissatisfied with its subject: it sees no character of excellency among men, equal to that pitch of esteem which it is capable of exerting; no object within the compass of human things ad-

equates to the strength of its affection. Nor can it stop any where in this self-expansive progress, or find repose after its highest flights, till it arrives at a Being of unbounded greatness and worth, on whom it may employ its sublimest powers without exhausting the subject, and give scope to the utmost force and fullness of its love without satiety or disgust. So that the nature of this Being corresponds to the nature of man; nor can his intelligent and moral powers obtain their entire end, but on the supposition of such a Being, and without a real sympathy and communication with him. The native propensity of the mind to reverence whatever is great and wonderful in nature, finds a proper object of homage in him who spread out the heavens and the earth, and who sustains and governs the whole of things. The admiration of beauty, the love of order, and the complacency we feel in goodness, must rise to the highest pitch, and attain the full vigour and joy of their operations, when they terminate in Him who is the sum and source of all perfection.

It is evident, from the slightest survey of morals, that how punctual soever one may be in performing the duties which result from our relations to mankind; yet to be quite deficient in performing those which arise from our relation to the Almighty, must argue a strange perversity of reason or depravity of heart. If imperfect degrees of worth attract our veneration, and if the want of it would imply an insensibility, or, which is worse, an aversion to merit; what lameness of affection, and immorality of character, must it be, to be unaffected with, and much more to be ill-affected to, a Being of superlative worth! To love society, or particular members of it, and yet to have no sense of our connection with its Head, no affection to our common Parent and Benefactor; to be concerned about the approbation or censure of our fellow-creatures, and yet to feel nothing of this kind towards Him who sees and weighs our actions with unerring wisdom and justice, and can fully reward or punish them; betrays equal madness and partiality of mind. It is plain, therefore, beyond all doubt, that some regards are due to the great Father of all, in whom every lovely and adorable quality combines to inspire veneration and homage.

As it has been observed already, that our affections depend on our opinions of their objects, and generally keep pace with them, it must be of the highest importance, and seems to be among the first duties we owe to the Author of our being, "to form the least imperfect, since we cannot form perfect conceptions of his character and administration." For such conceptions, thoroughly imbibed, will render our religion rational, and our dispositions refined. If our opinions are diminutive and distorted, our religion will be superstitious, and our temper abject. The foundation, then, of all true religion is a rational faith. And of a rational faith these seem to be the chief articles: To believe, "that an infinite all perfect Mind exists, who has no opposite nor any separate interest from that of his creatures:—that he superintends and governs all creatures and things:—that his goodness extends to all his creatures, in different degrees indeed, according to their respective natures, but without any partiality or envy:—that he does every thing for the best,

only a Subsidiary to the perfection and happiness of the whole:—particularly, that he directs and governs the actions of men,—inspects their actions,—distinguishes the good from the bad,—loves and befriends the former,—and justly reprobates and punishes the latter in this world,—and will, according to their respective deserts, reward the one, and punish the other in the next:—that, in fine, he has laid out every man on a scheme of virtue and happiness through an unlimited duration,—and is ever guiding the universe through its successive stages and periods, to higher degrees of perfection and felicity.” This is true theism, the glorious scheme of divine faith; a scheme exhibited in all the works of God, and executed through

This faith, well-founded and deeply felt, is nearly connected with a true moral taste, and hath a powerful efficacy on the temper and manners of the theist. He who admires goodness in others, and delights in the practice of it, must be conscious of a reigning order within, a rectitude and candor of heart which disposes him to entertain favourable apprehensions of men, and, from an impartial survey of things, to presume that good order and good meaning prevail in the universe; and if good meaning and good order, then an ordering and intending Mind, who is no enemy, no tyrant to his creatures, but a friend, a benefactor, an indulgent sovereign.—On the other hand, a bad man, having nothing goodly or generous to contemplate within, no right intentions, nor honesty of heart, suspects every person and every thing; and beholding nature through the gloom of a selfish and guilty mind, is either averse to the belief of a reigning order; or, if he cannot suppress the unconquerable anticipations of a governing mind, he is prone to tarnish the beauty of nature, and to impute malevolence, or blindness and impotence at least, to the Sovereign Ruler. He turns the universe into a forlorn and horrid waste; and transfers his own character to the Deity, by ascribing to him that uncommunicative grandeur, that arbitrary or revengeful spirit which he affects or admires in himself. As such a temper of mind naturally leads to atheism, or to a superstition full as bad; therefore, as far as that temper depends on the unhappy creature in whom it prevails, the propensity to atheism or superstition consequent thereto must be immoral. Farther, if it be true that the belief or sense of a Deity is natural to the mind, and the evidence of his existence reflected from his works so full as to strike even the most superficial observer with conviction; then the supplanting or corrupting that sense, or the want of due attention to that evidence, and, in consequence of both, a supine ignorance or a fixed unbelief of a Deity, multigues a bad temper, or an immoral turn of mind. In the case of invincible ignorance, or a very bad education, though nothing can be concluded directly against the character, yet the never ill passions and habits pervert the judgment, and by perverting the judgment terminate in atheism, then the case becomes plainly criminal.

But let casuists determine this as they will, a true faith in the divine character and adminis- tration is generally the consequence of a virtuous state of mind. The

man who is truly and habitually good, feels the love of order, of beauty, and goodness, in the strongest degree; and therefore cannot be insensible to those emanations of them which appear in all the works of God, nor help loving their Supreme Source and Model. He cannot but think, that He who has poured such beauty and goodness over all his works, must Himself delight in beauty and goodness, and what He delights in must be both amiable and happy. Some indeed there are, and it is pity there should be any such, who, through the unhappy influence of a wrong education, have entertained dark and unfriendly thoughts of a Deity and his administration, though otherwise of a virtuous temper themselves. However, it must be acknowledged, that such sentiments have, for the most part, a bad effect on the temper; and when they have not, it is because the undepraved affections of an honest heart are more powerful in their operation, than the speculative opinions of an ill-formed head.

But where-ever right conceptions of the Deity and his providence prevail, when he is considered as the inexhaustible source of light and love and joy, as acting in the joint character of a father and governor, imparting an endless variety of capacities to his creatures, and supplying them with every thing necessary to their full completion and happiness, what veneration and gratitude must such conceptions thoroughly believed excite in the mind! How natural and delightful must it be to one whose heart is open to the perception of truth, and of every thing fair, great, and wonderful in nature, to contemplate and adore Him, who is the First Fair, the First Great, and First Wonderful; in whom wisdom, power and goodness dwell vitally, essentially, originally, and act in perfect concert! What grandeur is here to fill the most enlarged capacity, what beauty to engage the most ardent love, what a mass of wonders in such exuberance of perfection, to astonish and delight the human mind through an unending duration!

If the Deity is considered as our supreme guardian and benefactor, as the father of mercies, who loves his creatures with infinite tenderness, and in a particular manner all good men, nay, who delights in goodness even in its most imperfect degrees; what resignation, what dependence, what generous confidence, what hope in God and his all-wise providence, must arise in the soul that is possessed of such amiable views of him! All those exercises of piety, and above all a superlative esteem and love, are directed to God as to their natural, their ultimate, and indeed their only adequate object: and though the immense obligations we have received from him may excite in us more lively feelings of divine goodness than a general and abstracted contemplation of it; yet the affections of gratitude and love are themselves of the generous disinterested kind, not the result of self-interest, or views of reward. A perfect character, in which we always suppose infinite goodness, guided by unerring wisdom, and supported by almighty power, is the proper object of perfect love; and though that character sustains to us the relation of a benefactor, yet the mind, deeply struck with that perfection, is quite lost amidst such a blaze of beau-

ty, and grows as it were insensible to those minuter irradiations of it upon itself. To talk, therefore, of a mercenary love of God, or which has fear for its principal ingredient, is equally impious and absurd. If we do not love the loveliest object in the universe for his own sake, no prospect of good or fear of ill can ever bribe our esteem, or captivate our love. These affections are too noble to be bought or sold, or bartered in the way of gain; worth, or merit, as their object, and their reward is something similar in kind. Whoever indulges such sentiments and affections towards the Deity, must be confirmed in the love of virtue, in a desire to imitate its all-perfect Pattern, and in a cheerful security that all his great concerns, those of his friends and of the universe, shall be absolutely safe under the conduct of unerring wisdom and unbounded goodness. It is in his care and providence alone that the good man, who is anxious for the happiness of all, finds perfect serenity, a serenity neither ruffled by partial ill, nor soured by private disappointment.

When we consider the unstained purity and absolute perfection of the divine nature, and reflect withal on the imperfection and various blemishes of our own, we must sink, or be convinced we ought to sink, into the deepest humility and prostration of soul before Him who is so wonderfully great and holy. When, farther, we call to mind what low and languid feelings we have of the Divine Preference and Majesty; what insensibility of his fatherly and universal goodness, nay, what ungrateful returns we have made to it; how far we come short of the perfection of his law, and the dignity of our own nature; how much we have indulged to the selfish passions, and how little to the benevolent ones; we must be conscious that it is our duty to repent of a temper and conduct so unworthy our nature, and unbecoming our obligations to its Author, and to resolve and endeavour to act a wiser and better part for the future.

Nevertheless, from the character which his works exhibit of him, from those delays or alleviations of punishment which offenders often experience, and from the merciful tenour of his administration in many other instances, the sincere penitent may entertain good hopes that his Parent and Judge will not be strict to mark iniquity, but will be propitious and favourable to him, if he honestly endeavours to avoid his former practices, and subdue his former habits, and to live in a greater conformity to the divine will for the future. If any doubts or fears should still remain, how far it may be consistent with the rectitude and equity of the divine government to let his iniquities pass unpunished; yet he cannot think it unsuitable to his paternal clemency and wisdom to contrive a method of retrieving the penitent offender, that shall unite and reconcile the majesty and mercy of his government. If reason cannot of itself suggest such a scheme, it gives at least some ground to expect it. But though natural religion cannot let in more light and assurance on so interesting a subject, yet it will teach the humble thief to wait with great submission for any farther intimations it may please the Supreme Governor to give of his will; to examine with candour and impartiality whatever evidence shall be proposed to him of a divine revelation, whether that evidence is natural or supernatural; to embrace it with veneration

and cheerfulness, if the evidence is clear and convincing; and finally, if it bring to light any new relations or connections, natural religion will persuade its sincere votary faithfully to comply with the obligations, and perform the duties which result from those relations and connections. — This is theism, piety, the completion of morality!

We must further observe, that all those affections which we supposed to regard the Deity as their immediate and primary object, are vital energies of the soul, and consequently exert themselves into act; and like all its other energies, gain strength or greater activity by that exertion. It is therefore our duty, as well as highest interest, often, at stated times, and by decent and solemn acts, to contemplate and adore the great Original of our existence, the Parent of all beauty, and of all good; to express our veneration and love, by an awful and devout recognition of his perfections; and to evidence our gratitude, by celebrating his goodness, and thankfully acknowledging all his benefits. It is likewise our duty, by proper exercises of sorrow and humiliation, to confess our ingratitude and folly; to signify our dependence on God, and our confidence in his goodness, by imploring his blessing and gracious concurrence in assisting the weakness, and curing the corruptions of our nature; and finally, to testify our sense of his authority, and our faith in his government, by devoting ourselves to do his will, and resigning ourselves to his disposal. These duties are not therefore obligatory, because the Deity needs or can be prouder by them; but as they are apparently decent and moral; suitable to the relations he sustains of our Creator, Benefactor, Law-giver and Judge; expressive of our state and obligations; and improving to our tempers, by making us more rational, social, godlike, and consequently more happy.

We have now considered internal piety, or the worship of the mind, that which is in spirit and in truth; we shall conclude the section with a short account of that which is external. External worship is founded on the same principles as internal, and of a strict moral obligation. It is either private or public. Devotion, that is inward, or purely intellectual, is too spiritual and abstracted an operation for the bulk of mankind. The operations of their minds, such especially as are employed on the most sublime immaterial objects, must be assisted by their outward organs, or by some help from the imagination, otherwise they will be soon dissipated by sensible impressions, or grow tiresome if too long continued. Ideas are such fleeting things that they must be fixed, and so subtle that they must be exprest and delineated, as it were, by sensible marks and images: otherwise we cannot attend at them, nor be much affected to them. Therefore verbal adoration, prayer, praise, thanksgiving and confession, are admirable aids to inward devotion, fix our attention, compose and enliven our thoughts, impress us more deeply with a sense of the awful presence in which we are, and, by a natural and mechanical sort of influence, tend to heighten those devout feelings and affections which we ought to entertain, and after this manner reduce into formal and explicit act.

This holds true in an higher degree in the case of public worship, where the presence of our fellow-creatures, and the powerful contagion of the social affections, conspire to kindle and spread the devout flame with greater energy.

energy. To conclude: As God is the parent and head of the social system; as he has formed us for a social state; as by one we find the best security against the ills of life, and in the other enjoy its greatest comforts; and as, by means of both, our nature attains its highest improvement and perfection; and moreover, as there are public blessings and crimes in which we all share in some degree, and public wants and dangers to which all are exposed; it is therefore evident, that the various and solemn offices of public religion, are duties of indispensable moral obligation, among the best cements of society, the firmest prop of government, and the fairest ornament of both.

Of Practical Ethics, or the Culture of the Mind.

We have now gone through a particular detail of the several duties we owe to ourselves, to society, and to God. In considering the first order of duties, we just touched on the methods of acquiring the different kinds of goods which we are led by nature to pursue; only we left the consideration of the method of acquiring the moral goods of the mind to a section by itself, because of its singular importance. This section, then, will contain a brief enumeration of the arts of acquiring virtuous habits, and of eradicating vitious ones, as far as is consistent with the brevity of such a work; a subject of the utmost difficulty as well as importance in morals; to which, nevertheless, the least attention has been generally given by moral writers, especially those of a modern date. This will properly follow a detail of duty, as it will direct us to such means or helps as are most necessary and conducive to the practice of it.

In the first part of this inquiry we traced the order in which the passions shoot up in the different periods of human life. That order is not accidental, nor dependent on the caprice of men, or the influence of custom and education; but arises from the original constitution and laws of our nature; of which this is one, *viz.* "That sensible objects make the first and strongest impressions on the mind." These, by means of our outward organs, being conveyed to the mind, become objects of its attention, on which it reflects when the outward objects are no longer present, or, in other words, when the impressions upon the outward organs cease. These objects of the mind's reflection are called *ideas* or *images*. Towards these, by another law of our nature, we are not altogether indifferent; but correspondent movements of desire or aversion, love or hatred, arise, according as the objects of which they are images or copies made an agreeable or disagreeable impression on our organs. Those ideas and affections which we experience in the first period of life, we refer to the body, or to sense; and the taste which is formed towards them, we call a *sensible*, or a *merely natural* taste; and the objects corresponding to them we in general call *good* or *pleasant*.

But, as the mind moves forward in its course, it extends its views, and receives a new and more complex set of ideas, in which it observes uniformity, variety, similitude, symmetry of parts, reference to an end, novelty, grandeur. These compose a vast train and diversity of ima-

gery, which the mind compounds, divides, and moulds into a thousand forms, in the absence of those objects which first introduced it. And this more complicated imagery suggests a new train of desires and affections, full as sprightly and engaging as any which have yet appeared. This whole class of perceptions or impressions is referred to the imagination, and forms an higher taste than the sensible, and which has an immediate and mighty influence on the finer passions of our nature, and is commonly termed a *fine taste*.

The objects which correspond to this taste we use to call beautiful, harmonious, great, or wonderful, or, in general, by the name of *beauty*.

The mind still pushing onwards, and increasing its stock of ideas, ascends from those to an higher species of objects, *viz.* the order and mutual relations of minds to each other, their reciprocal affections, characters, actions, and various affects. In these it discovers a beauty, a grandeur, a decorum more interesting and alluring than in any of the former kinds. These objects, or the images of them, passing in review before the mind, do, by a necessary law of our nature, call forth another and nobler set of affections, as admiration, esteem, love, honour, gratitude, benevolence, and others of the like tribe. This class of perceptions, and their correspondent affections, we refer, because of their objects (manners,) to a moral sense; and call the taste or temper they excite, *moral*: and the objects which are agreeable to this taste or temper we denominate by the general name of *moral beauty*; in order to distinguish it from the other, which is termed *natural*.

These different sets of ideas or images are the materials about which the mind employs itself; which it blends, ranges, and diversifies ten thousand different ways. It feels a strong propensity to connect and associate those ideas among which it observes any similitude, or any aptitude, whether original and natural, or customary and artificial, to suggest each other. See METAPHYSICS.

But whatever the reasons are, whether similitude, co-existence, causality, or any other aptitude or relation, why any two or more ideas are connected by the mind at first, it is an established law of our nature, "That when two or more ideas have often started in company, they form so strong an union, that it is very difficult ever after to separate them." Thus the lover cannot separate the idea of merit from his mistress; the courtier that of dignity from his title or ribbon; the miser that of happiness from his bags.—It is these associations of worth or happiness with any set of objects or images that form our taste or complex idea of good. By another law of our nature, "our affections follow and are governed by this taste; and to these affections our character and conduct are similar and proportioned, on the general tenor of which our happiness principally depends."

As all our leading passions, then, depend on the direction which our taste takes, and as it is always of the same strain with our leading associations, it is worth while to inquire a little more particularly how these are formed, in order to detect the secret sources from whence our passions derive their principal strength, their various rises

and falls. For this will give us the true key to their management, and let us into the right method of correcting the bad, and improving the good.

No kind of objects makes so powerful an impression on us as those which are immediately impressed on our senses, or strongly painted on our imaginations. Whatever is purely intellectual, as abstracted or scientific truths, the subtle relations and difference of things, has a fainter sort of existence in the mind; and, though it may exercise and whet the memory, the judgment, or the reasoning powers, gives hardly any impulse at all to the active powers, the passions, which are the main springs of motion. On the other hand, were the mind entirely under the direction of sense, and impressible only by such objects as are present and strike some of the outward organs, we should then be precisely in the state of the brute creation, and be governed solely by instinct or appetite, and have no power to controul whatever impressions are made upon us. Nature has therefore endued us with a middle faculty, wonderfully adapted to our mixed state; which holds partly of sense, and partly of reason; being strongly allied to the former, and the common receptacle in which all the notices that come from that quarter are treasured up; and yet greatly subservient and ministerial to the latter, by giving a body, a coherence, and beauty to its conceptions. This middle faculty is called the *imagination*, one of the most busy and fruitful powers of the mind. Into this common storehouse are likewise carried all those moral images or forms which are derived from our moral faculties of perception; and there they often undergo new changes and appearances, by being mixed and wrought up with the images and forms of sensible or natural things. By this coalition of imagery, natural beauty is dignified and heightened by moral qualities and perfections, and moral qualities are at once exhibited and set off by natural beauty. The sensible beauty, or good, is refined from its dross by partaking of the moral; and the moral receives a stamp, a visible character and currency from the sensible.

As we are first of all accustomed to sensible impressions and sensible enjoyments, we contract early a sensual relish or love of pleasure in the lower sense of the word. In order, however, to justify this relish, the mind, as it becomes open to higher perceptions of beauty and good, borrows from thence a nobler set of images, as fine taste, generosity, social affection, friendship, good-fellowship, and the like; and, by dressing out the old pursuits with these new ornaments, gives them an additional dignity and lustre. By these ways the desire of a table, love of finery, intrigue, and pleasure, are vastly increased beyond their natural pitch, having an impulse combined of the force of the natural appetites and of the superadded strength of those passions which tend to the moral species. — When the mind becomes more sensible to those objects or appearances, in which it perceives beauty, uniformity, grandeur, and harmony, as fine cloaths, elegant furniture, plate, pictures, gardens, houses, equipage, the beauty of animals, and particularly the attractions of the sex; to these objects the mind is led by nature, or taught by custom, the opinion and example of others, to annex certain ideas of moral character, dignity, decorum, ho-

nour, liberality, tenderness, and active or social enjoyment. The consequence of this association is, that the objects to which these are annexed, must rise in their value, and be pursued with proportionable ardor. The enjoyment of them is often attended with pleasure; and the mere possession of them, where that is wanting, frequently draws respect from one's fellow-creatures: this respect is, by many, thought equivalent to the pleasure of enjoyment. Hence it happens, that the idea of happiness is connected with the mere possession; which is therefore eagerly fought after, without any regard to the generous use, or honourable enjoyment. Thus the passion resting on the means, not the end, *i. e.* losing sight of its natural object, becomes wild and extravagant.

In fine, any object, or external denomination, a staff, a garter, a cup, a crown, a title, may become a moral badge or emblem of merit, magnificence, or honour, according as these have been found or thought by the possessors or admirers of them to accompany them; yet, by the deception formerly mentioned, the merit or the conduct which entitled, or should entitle, to those marks of distinction, shall be forgot or neglected, and the badges themselves be passionately affected, or pursued, as including every excellency. If these are attained by any means, all the concomitants which nature, custom, or accidents have joined to them, will be supposed to follow of course. Thus moral ends, with which the unhappy admirer is apt to colour over his passion and views, will, in his opinion, justify the most immoral means, as prostitution, adulation, fraud, treachery, and every species of knavery, whether more open or more disguised.

When men are once engaged in active life, and find that wealth and power, generally called *interest*, are the great avenues to every kind of enjoyment, they are apt to throw in many engaging moral forms to the object of their pursuit, in order to justify their passion, and varnish over the measures they take to gratify it; as, independency on the vices or passions of others, provision and security to themselves and friends, prudent oeconomy or well-placed charity, social communication, superiority to their enemies who are all villains, honourable service, and many other ingredients of merit. To attain such capacities of usefulness or enjoyment, what arts, nay, what meanesses can be thought blameable by those cool pursuers of interest! — Nor have they, whom the gay world is pleased to indulge with the title of *men of pleasure*, their imaginations less pregnant with moral images, with which they never fail to ennoble, or, if they cannot do that, to palliate their gross pursuits. Thus, admiration of wit, of sentiments and merit, friendship, love, generous sympathy, mutual confidence, giving and receiving pleasure, are the ordinary ingredients with which they season their gallantry and pleasurable entertainments; and by which they impose on themselves, and endeavour to impose on others, that their amours are the joint issue of good sense and virtue.

These associations, variously combined and proportioned by the imagination, form the chief private passions which govern the lives of the generality; as the love of action, of pleasure, power, wealth, and fame: they influence the defensive, and affect the public passions, and raise joy

joy or sorrow, as they are gratified or disappointed. So that, in effect, these associations of good and evil, beauty and deformity, and the passions they raise, are the main hinges of life and manners, and the great sources of our happiness or misery. It is evident, therefore, that the whole of moral culture must depend on giving a right direction to the leading passions, and duly proportioning them to the value of the objects or goods pursued, under what name soever they may appear.

Now, in order to give them this right direction and due proportion, it appears, from the foregoing detail, that those associations of ideas, upon which the passions depend, must be duly regulated: that is to say, as an exorbitant passion for wealth, pleasure, or power, flows from an association or opinion that more beauty and good, whether natural or moral, enters into the enjoyment or possession of them, than really belongs to either; therefore, in restoring those passions to their just proportion, we must begin with correcting the opinion, or breaking the false association; or, in other words, we must decompose the complex phantom of happiness or good, which we fondly admire; disunite those ideas, that have no natural alliance; and separate the original idea of wealth, power, or pleasure, from the foreign mixtures incorporated with it, which enhance its value, or give it its chief power to enchant and seduce the mind. For instance, let it be considered how poor and inconsiderable a thing wealth is, if it be disjoined from real use, or from ideas of capacity in the possessor to do good, from independency, generosity, provision for a family or friends, and social communication with others. By this standard let its true value be fixed; let its misapplication, or unbenevolent enjoyment, be accounted sordid and infamous; and nothing worthy or estimable be ascribed to the mere possession of it, which is not borrowed from its generous use.

If that complex form of good which is called *pleasure*, engages us, let it be analysed into its constituent principles, or those allurements it draws from the heart and imagination, in order to heighten the low part of the indulgence; let the separate and comparative moment of each be distinctly ascertained, and deduced from that gross part; and this remainder of the accumulative enjoyment will dwindle down into a poor, insipid, transitory thing. In proportion as the opinion of the good pursued abates, the admiration must decay, and the passion lose strength of course. One effectual way to lower the opinion, and consequently to weaken the habit founded on it, is to practice lesser pieces of self-denial, or to abstain, to a certain pitch, from the pursuit or enjoyment of the favourite object; and, that this may be the more easily accomplished, one must avoid those occasions, that company, those places, and the other circumstances that inflame one, and endeared the other: And, as a counter-process, let higher or even different enjoyments be brought in view, other passions played upon the former, different places frequented, other exercises tried, company kept with persons of a different or more correct way of thinking, both in natural and moral subjects.

As much depends on our setting out well in life, let the youthful fancy, which is apt to be very florid and luxuriant, be early accustomed, by instruction, example,

and significant moral exercises, nay, by looks, gestures, and every other testimony of just approbation or blame, to annex ideas of merit, honour, and happiness—not to birth, dress, rank, beauty, fortune, power, popularity, and the like outward things,—but to moral and truly virtuous qualities, and to those enjoyments which spring from a well-informed judgment, and a regular conduct of the affections, especially those of the social and disinterested kind. Such dignified forms of beauty and good, often suggested, and, by moving pictures and examples, warmly recommended to the imagination, enforced by the authority of conscience, and demonstrated by reason to be the surest means of enjoyment, and the only independent, undeprivable and durable goods, will be the best counter-balance to meaner passions, and the firmest foundation and security to virtue.

It is of great importance to the forming a just taste, or pure and large conceptions of happiness, to study and understand human nature well, to remember what a complicated system it is, particularly to have deeply imprinted on our mind that gradation of senses, faculties, and powers of enjoyment formerly mentioned, and the subordination of goods resulting from thence, which nature points out, and the experience of mankind confirms; who, when they think seriously, and are not under the immediate influence of some violent prejudice or passion, prefer not the pleasures of action, contemplation, society, and most exercises and joys of the moral kind, as friendship, natural affection, and the like, to all sensual gratifications whatsoever? Where the different species of pleasure are blended into one complex form, let them be accurately distinguished, and be referred each to its proper faculty and sense, and examined apart what they have peculiar, what common with others, and what foreign and adventitious. Let wealth, grandeur, luxury, love, fame, and the like, be tried by this test, and their true alloy will be found out.—Let it be farther considered, whether the mind may not be easy, and enjoy itself greatly, though it want many of those elegancies and superfluities of life which some possess, or that load of wealth and power which others eagerly pursue, and under which they groan. Let the difficulty of attaining, the precariousness of possessing, and the many abatements in enjoying overgrown wealth and envied greatness, of which the weary possessors so frequently complain, as the hurry of business, the burden of company, of paying attendance to the few, and giving it to the many, the cares of keeping, the fears of losing, and the desires of increasing what they have, and the other troubles which accompany this pitiful drudgery and pompous servitude; let these and the like circumstances be often considered that are conducive to the removing or lessening the opinion of such goods, and the attendant passion or set of passions will decay of course.

Let the peculiar bent of our nature and character be observed, whether we are most inclined to form associations and relish objects of the sensible, intellectual, or moral kind. Let that which has the ascendant be particularly watched; let it be directed to right objects, be improved by proportioned exercises, and guarded by proper checks from an opposite quarter. Thus, the sensible

turn may be exalted by the intellectual and a taste for the beauty of the fine arts, and both may be made subservient to convey and rivet sentiments highly moral and public-spirited. This inward survey must extend to the strength and weakness of one's nature, one's condition, connections, habits, fortune, studies, acquaintance, and the other circumstances of one's life; from which every man will form the justest estimate of his own dispositions and character, and the best rules for correcting and improving them. And, in order to do this with more advantage, let those times or critical seasons be watched when the mind is best disposed towards a change, and let them be improved by vigorous resolutions, promises, or whatever else will engage the mind to persevere in virtue. Let the conduct, in fine, be often reviewed, and the causes of its corruption or improvement be carefully observed.

It will greatly conduce to refine the moral taste and strengthen the virtuous temper, to accustom the mind to the frequent exercise of moral sentiments and determinations, by reading history, poetry, particularly of the picturesque and dramatic kind, the study of the fine arts; by conversing with the most eminent for good-sense and virtue; but, above all, by frequent and repeated acts of humanity, compassion, friendship, politeness, and hospitality. It is exercise gives health and strength. He that reasons most frequently, becomes the wisest, and most enjoys the pleasures of wisdom. He who is most often affected by objects of compassion in poetry, history, or real life, will have his soul most open to pity and its delightful pains and duties. So he also who practices most diligently the offices of kindness and charity, will by it cultivate that disposition, from whence all his pretensions to personal merit must arise, his present and his future happiness.

An useful and honourable employment in life will administer a thousand opportunities of this kind, and greatly strengthen a sense of virtue and good affections, which must be nourished by right training, as well as our understandings. For such an employment, by enlarging one's experience, giving an habit of attention and caution, or obliging one, from necessity or interest, to keep a guard over the passions, and study the outward decencies and appearances of virtue, will by degrees produce good habit, and at length insinuate the love of virtue and honesty for its own sake.

It is a great inducement to the exercise of benevolence, to view human nature in a favourable light, to observe the characters and circumstances of mankind on the fairest sides, to put the best constructions on their actions they will bear, and to consider them as the result of partial and mistake, rather than ill affections, or, at worst, as the excesses of a pardonable self-love, seldom or never the effects of pure malice.

Above all, the nature and consequences of virtue and vice, their consequences being the law of our nature and will of heaven; the light in which they appear to our supreme Parent and Law-giver, and the reception they will meet with from him; must be often attended to. The exercises of piety, as adoration and praise of the Divine Excellency, invocation of and dependence on his aid, confession,

thanksgiving, and resignation, are habitually to be indulged, and frequently performed, not only as medicinal, but highly improving to the temper.

To conclude: It will be of admirable efficacy towards eradicating bad habits, and implanting good ones, frequently to contemplate human life as the great nursery of our future and immortal existence, as that state of probation in which we are to be educated for a divine life; to remember that our virtues or vices will be immortal as ourselves, and influence our future as well as our present happiness, and therefore that every disposition and action is to be regarded as pointing beyond the present to an immortal duration. An habitual attention to this wide and important connection will give a vast compass and dignity to our sentiments and actions, a noble superiority to the pleasures and pains of life, and a generous ambition to make our virtue as immortal as our being.

Motives to Virtue from personal Happiness.

We have already considered our obligations to the practice of virtue, arising from the constitution of our nature, by which we are led to approve a certain order and economy of affections, and a certain course of action correspondent to it.—But besides this, there are several motives which strengthen and secure virtue, though not themselves of a moral kind. These are, its tendency to personal happiness, and the contrary tendency of vice. "Personal happiness arises, either from the state of a man's own mind, or from the state and disposition of external causes towards him."

We shall first examine the "tendency of virtue to happiness with respect to the state of a man's own mind."—This is a point of the utmost consequence in morals; because, unless we can convince ourselves, or shew to others, that, by doing our duty, or fulfilling our moral obligations, we consult the greatest satisfaction of our own mind, or our highest interest on the whole, it will raise strong and often unshunnable prejudices against the practice of virtue, especially whenever there arises any appearance of opposition between our duty and our satisfaction or interest. To creatures so desirous of happiness and averse to misery as we are, and often so oddly situated amidst contending passions and interests, it is necessary that virtue appear not only an honourable, but a pleasing and beneficent form. And in order to justify our choice to ourselves, as well as before others, we must ourselves feel, and be able to avow in the face of the whole world, that her ways are ways of pleasantness, and her paths the paths of peace. This will shew, beyond all contradiction, that we not only approve, but can give a sufficient reason for what we do.

Let a man in a cool hour, when he is disengaged from business, and undisturbed by passion, as such cool hours will sometimes happen, sit down, and seriously reflect with himself what state or temper of mind he would chuse to feel and indulge, in order to be easy and to enjoy himself. Would he chuse, for that purpose, to be in a constant dissipation and hurry of thought; to be disturbed in the exercise of his reason; to have various, and often interfering phantoms of good playing before his imagination, soliciting and distracting him by turns, now soothing him

with

with amusing hopes, then torturing him with anxious fears; and to approve this minute what he shall condemn the next? Would he chuse to have a strong and painful sense of every petty injury; quick apprehensions of every impending evil; incessant and insatiable desires of power, wealth, honour, pleasure; an irreconcilable antipathy against all competitors and rivals; insolent and tyrannical dispositions to all below him; fawning, and at the same time envious, dispositions to all above him; with dark suspicions and jealousies of every mortal? Would he chuse neither to love, nor to be beloved of any; to have no friend in whom to confide, or with whom to interchange his sentiments or designs; no favourite, on whom to bestow his kindness, or vent his passions; in fine, to be conscious of no merit with mankind, no esteem from any creature, no good affection to his Maker, no concerns for or hopes of his approbation; but, instead of all these, to hate, and know that he is hated, to contemn, and know that he is contemned by all; by the good because he is so unlike, and by the bad because he is so like themselves; to hate or to dread the very Being that made him; and, in short, to have his breast the seat of pride and passion, petulance and revenge, deep melancholy, cool malignity, and all the other furies that ever possessed and tortured mankind?—Would our calm inquirer after happiness pitch on such a state, and such a temper of mind, as the most likely means to put him in possession of his desired ease and self-enjoyment?

Or would he rather chuse a serene and easy flow of thought; a reason clear and composed; a judgment unbiassed by prejudice, and undistracted by passion; a sober and well-governed fancy, which presents the images of things true and unmixed with delusive and unnatural charms, and therefore administers no improper or dangerous fuel to the passions, but leaves the mind free to chuse or reject, as becomes a reasonable creature; a sweet and sedate temper, not easily ruffled by hopes or fears, prone neither to suspicion nor revenge, apt to view men and things in the fairest lights, and to bend gently to the humours of others rather than obstinately to contend with them? Would he chuse such moderation and continence of mind, as neither to be ambitious of power, fond of honours, covetous of wealth, nor a slave to pleasure; a mind of course neither elated with success, nor dejected with disappointment; such a modest and noble spirit as supports power without insolence, wears honours without pride, uses wealth without profusion or parsimony; and rejoices more in giving than in receiving pleasure; such fortitude and equanimity as rises above misfortunes, or turns them into blessings; such integrity and greatness of mind, as neither flatters the vices, nor triumphs over the follies of men; as equally spurns servitude and tyranny, and will neither engage in low designs, nor abet them in others? Would he chuse, in fine, such mildness and benignity of heart as takes part in all the joys, and refuses none of the sorrows of others; stands well affected to all mankind; is conscious of meriting the esteem of all, and of being beloved by the best; a mind which delights in doing good without any shew, and yet arrogates nothing on that account; rejoices in loving and being loved by its Maker, acts ever under his eye, resigns

itself to his providence, and triumphs in his approbation? Which of these dispositions would be his choice, in order to be contented, serene, and happy?—The former temper is *vice*, the latter *virtue*. Where one prevails, there misery prevails, and by the generality is acknowledged to prevail. Where the other reigns, there happiness reigns, and by the confession of mankind is acknowledged to reign. The perfection of either temper is misery, or happiness, in perfection. Therefore every approach to either extreme, is an approach to misery, or to happiness; that is to say, every degree of vice or virtue is accompanied with a proportionable degree of misery or happiness.

The principal alleviations of a virtuous man's calamities are these:—that, though some of them may have been the effect of his imprudence, or weakness; yet few of them are sharpened by a sense of guilt, and none of them by a consciousness of wickedness, which surely is their keenest sting:—that they are common to him with the best of men:—that they seldom or never attack him quite unprepared, but rather guarded with a consciousness of his own sincerity and virtue, with a faith and trust in providence, and a firm resignation to its perfect orders:—that they may be improved as means of correction, or materials to give scope and stability to his virtues:—and, to name no more, they are considerably lessened, and often sweetened to him, by the general sympathy of the wise and good.

His enjoyments are more numerous, or, if less numerous, yet more intense, than those of bad men: for he shares in the joys of others by rebound; and every increase of general or particular happiness is a real addition to his own. It is true, his friendly sympathy with others subjects him to some pains which the hard-hearted wretch does not feel; yet to give a loose to it, is a kind of agreeable discharge. It is such a sorrow as he loves to indulge; a sort of pleasing anguish, that sweetly melts the mind, and terminates in a self-approving joy. Tho' the good man may want means to execute, or be disappointed in the success of his benevolent purposes; yet he is still conscious of good affections; and that consciousness is an enjoyment of a more delightful flavour than the greatest triumphs of successful vice. If the ambitious, covetous, or voluptuous, are disappointed, their passions recoil upon them with a fury proportioned to their opinion of the value of what they pursue, and their hope of success; while they have nothing within to balance the disappointment, unless it is an useful fund of pride, which however frequently turns mere accidents into mortifying affronts, and exalts grief into rage and frenzy. Whereas the meek, humble, and benevolent temper is its own immediate reward; is satisfied from within; and as it magnifies greatly the pleasure of success, so it wonderfully alleviates, and in a manner annihilates, all pain for the want of it.

As the good man is conscious of loving and wishing well to all mankind, he must be sensible of his deserving the esteem and goodwill of all; and this supposed reciprocity of social feelings, is, by the very frame of our nature, made a source of very intense and enlivening joys. By this sympathy of affections and interests he feels himself intimately united with the human race; and

being sensibly alive over the whole system, his heart receives and becomes responsive to every touch given to any part. So that he gathers contentment and delight from the pleased and happy state of those around him, from accounts and relations of such happiness, from the very countenances, gestures, voices, and sounds even of creatures foreign to our kind, whose signs of joy and contentment he can any way discern.

Nor do those generous affections stop any other natural source of joy whatever, or deaden his sense of any innocent gratification. They rather keep the several senses and powers of enjoyment open and disengaged, intense, and uncorrupted by riot or abuse; as is evident to any one who considers the dissipated unfeeling state of men of pleasure, ambition, or interest, and compares it with the serene and gentle state of a mind at peace with itself, and friendly to all mankind, unruddied by any violent emotion, and sensible to every good-natured and alluring joy.

It were easy, by going through the different sets of affections, to shew, that it is only by maintaining the proportion settled there that the mind arrives at true repose and satisfaction. If fear exceeds that proportion, it sinks into melancholy and dejection. If anger passes just bounds, it ferments into rage and revenge, or subsides into a fullen corroding gloom, which embitters every good, and renders one exquisitely sensible to every ill. The private passions, the love of honour especially, whose impulses are more generous as its effects are more diffusive, are instruments of private pleasure; but if they are disproportioned to our wants, or to the value of the several objects, or to the balance of other passions equally necessary and more amiable, they become instruments of intense pain and misery. For, being now delirious of that counterpoise which held them at a due pitch, they grow turbulent, peevish, and revengeful, the cause of constant restlessness and torment, sometimes flying out into a wild delirious joy, at other times settling into a deep splenetic grief. The concert between reason and passion is then broke: all is dissonance and distraction within. The mind is out of frame, and feels an agony proportioned to the violence of the reigning passion.

The case is much the same, or rather worse, when any of the particular kind affections are out of their natural order and proportion; as happens in the case of effeminate pity, exorbitant love, parental dotage, or any party passion, where the just regards to society are supplanted. The more social and disinterested the passion is, it breaks out into the wilder excesses, and makes the more dreadful havoc, both within and abroad, as is but too apparent in those cases where a false species of religion, honour, zeal, or party-rage, has seized on the natural enthusiasm of the mind, and worked it up to madness. It breaks through all ties natural and civil, counteracts the most sacred and solemn obligations, silences every other affection whether public or private, and transforms the most gentle natures into the most savage and inhuman.

Whereas the man who keeps the balance of affection even, is easy and serene in his motions; mild, and yet affectionate; uniform and consistent with himself; is not

liable to disagreeable collisions of interests and passions; gives always place to the most friendly and humane affections; and never to dispositions or acts of resentment, but on high occasions, when the security of the private, or welfare of the public system, or the great interests of mankind necessarily require a noble indignation; and even then he observes a just measure in wrath; and last of all, he proportions every passion to the value of the object he affects, or to the importance of the end he pursues.

To sum up this part of the argument, the honest and good man has eminently the advantage of the knavish and selfish wretch in every respect. The pleasures which the last enjoys flow chiefly from external advantages and gratifications; are superficial and transitory; dashed with long intervals of satiety, and frequent returns of remorse and fear; dependent on favourable accidents and conjunctures; and subjected to the humours of men. But the good man is satisfied from himself; his principal possessions lie within, and therefore beyond the reach of the caprice of men or fortune; his enjoyments are exquisite and permanent; accompanied with no inward checks to damp them, and always with ideas of dignity and self-approbation; may be tasted at any time, and in any place. The gratifications of vice are turbulent and unnatural, generally arising from the relief of passions in themselves intolerable, and issuing in tormenting reflections; often irritated by disappointment, always inflamed by enjoyment, and yet ever cloyed with repetition. The pleasures of virtue are calm and natural; flowing from the exercise of kind affections, or delightful reflections in consequence of them; not only agreeable in the prospect but in the present feeling; they never fatigue, or lose their relish; nay, rather the admiration of virtue grows stronger every day; and not only is the desire but the enjoyment heightened by every new gratification; and, unlike to most others, it is increased, not diminished, by sympathy and communication. In fine, the satisfactions of virtue may be purchased without a bribe, and possessed in the humblest as well as the most triumphant fortune; they can bear the strictest review, do not change with circumstances, nor grow old with time. Force cannot rob, nor fraud cheat us of them; and, to crown all, instead of abating, they enhance every other pleasure.

But the happy consequences of virtue are seen, not only in the internal enjoyments it affords a man, but "in the favourable disposition of external causes towards him, to which it contributes."

As virtue gives the sober possession of one's self and the command of one's passions, the consequence must be, heart's ease, and a fine natural flow of spirits, which conduce more than any thing else to health and long life. Violent passions, and the excesses they occasion, gradually impair and wear down the machine. But the calm placid state of a temperate mind, and the healthful exercises in which virtue engages her faithful votaries, preserve the natural functions in full vigour and harmony, and exhilarate the spirits, which are the chief instruments of action.

It may by some be thought odd to assert, that virtue is no enemy to a man's fortune in the present state of things.

things.—But if, by fortune, be meant a moderate or competent share of wealth, power, or credit, not overgrown degrees of them, what should hinder the virtuous man from obtaining that? He cannot cringe or fawn, it is true; but he can be civil and obliging as well as the knave: and surely, his civility is more alluring, because it has more manliness and grace in it than the mean adulation of the other: he cannot cheat or undermine; but he may be cautious, provident, watchful of occasions, and equally prompt with the rogue in improving them: he scorns to prostitute himself as a pander to the passions, or as a tool to the vices of mankind; but he may have as found an understanding, and as good capacities for promoting their real interests, as the veriest court-slave; and then, he is more faithful and true to those who employ him. In the common course of business, he has the same chances with the knave of acquiring a fortune, and rising in the world. He may have equal abilities, equal industry, equal attention to business; and in other respects lie has greatly the advantage of him. People love better to deal with him; they can trust him more; they know he will not impose on them, nor take advantage of them, and can depend more on his word than on the oath or strongest securities of others. Whereas what is commonly called cunning, which is the offspring of ignorance, and constant companion of knavery, is not only a mean-spirited, but a very short-sighted talent, and a fundamental obstacle in the road of business. It may procure indeed immediate and petty gains; but it is attended with dreadful abatements, which do more than over-balance them, both as it sinks a man's credit when discovered, and cramps that largeness of mind, which extends to the remotest as well as the nearest interest, and takes in the most durable equally with the most transient gains. It is therefore easy to see how much a man's credit and reputation, and consequently his success, depend on his honesty and virtue.

With regard to security and peace with his neighbours, it may be thought, perhaps, that the man of a quiet forgiving temper, and a flowing benevolence and courtesy, is much exposed to injury and affronts from every proud or peevish mortal who has the power or will to do mischief. If we suppose, indeed, this quietness and gentleness of nature accompanied with cowardice or pusillanimity, this may often be the case; but in reality, the good man is bold as a lion, and so much the bolder for being the calmer. Such a person will hardly be a butt to mankind. The ill-natured will be afraid to provoke him, and the good-natured will not incline to do it. Besides, true virtue, which is conducted by reason, and exerted gracefully and without parade, is a most insinuating and commanding thing; if it cannot disarm malice and resentment at once, it will wear them out by degrees, and subdue them at length. How many have, by favours, and prudently yielding, triumphed over an enemy who would have been inflamed into tenfold rage by the fiercest opposition? In fine, goodness is the most universally popular thing that can be.

To conclude, the good man may have some enemies, but he will have more friends; and having given so many marks of private friendship or public virtue, he can hard-

ly be destitute of a patron to protect, or a sanctuary to entertain him, or to entertain or protect his children when he is gone. Though he should have little else to leave them, he bequeaths them the fairest, and generally the most unenvied, inheritance of a good name; which, like good seed sown in the field of futurity, will often raise up unsolicited friends, and yield a benevolent harvest of unexpected charities. But should the fragrance of the parent's virtue prove offensive to a perverse or envious age, or even draw persecution on the friendless orphans, there is One in heaven, who will be more than a father to them, and recompense their parent's virtues by showering down blessings on them.

Motives to Virtue from the BEING and PROVIDENCE of God.

BESIDES the interesting motive mentioned in the last section, there are two great motives to virtue, strictly connected with human life, and resulting from the very constitution of the human mind. The first is the being and providence of God; the second is the immortality of the soul, with future rewards and punishments.

It appears from what has been said, that man, by the constitution of his nature, is designed to be a religious creature. He is intimately connected with the Deity, and necessarily dependent on him. From that connection and necessary dependence result various obligations and duties; without fulfilling which, some of his sublimest powers and affections would be incomplete and abortive. If he be likewise an immortal creature, and if his present conduct shall affect his future happiness in another state as well as in the present; it is evident, that we take only a partial view of the creature if we leave out this important property of his nature, and make a partial estimate of human life if we strike out of the account, or over-look, that part of his duration which runs out into eternity.

It is evident, that “to have a respect to the Deity in our temper and conduct, to venerate and love his character, to adore his goodness, to depend upon and resign ourselves to his providence, to seek his approbation, and act under a sense of his authority, is a fundamental part of moral virtue, and the completion of the highest destination of our nature.”

But as piety is an essential part of virtue, so likewise it is a great support and enforcement to the practice of it. To contemplate and admire a being of such transcendent dignity and perfection as God, must naturally and necessarily open and enlarge the mind, give a freedom and ampleness to its powers, and a grandeur and elevation to its aims. For, “the greatness of an object, and the excellency of the act of any agent about a transcendent object, doth mightily tend to the enlargement and improvement of his faculties.” Little objects, mean company, mean cares, and mean business, cramp the mind, contract its views, and give it a creeping air and deportment. But when it soars above mortal cares and mortal pursuits into the regions of divinity, and converses with the Greatest and Best of Beings, it spreads itself into a wider compass, takes higher flights in reason and goodness, and becomes Godlike in its air and manners. Virtue is, if one may say so, both the effect and cause of largeness of mind. It requires

requires that one think freely, and act nobly. Now, what can conduce more to freedom of thought and dignity of action, than to conceive worthily of God, to reverence and adore his unrivalled excellency, to imitate and transcribe that excellency into our own nature, to remember our relation to him, and that we are the image and representatives of his glory to the rest of the creation? Such feelings and exercises must and will make us scorn all actions that are base, unhandsome, or unworthy our state; and the relation we stand in to God will irradiate the mind with the light of wisdom, and ennoble it with the liberty and dominion of virtue.

The influence and efficacy of religion may be considered in another light. We all know that the presence of a friend, a neighbour, or any number of spectators, but especially an august assembly of them, uses to be a considerable check upon the conduct of one who is not lost to all sense of honour and shame, and contributes to restrain many irregular sallies of passion. In the same manner we may imagine, that the awe of some Superior Mind, who is supposed privy to our secret conduct, and armed with full power to reward or punish it, will impose a restraint on us in such actions as fall not under the controul or animadversion of others. If we go still higher, and suppose our inmost thoughts and darkest designs, as well as our most secret actions, to lie open to the notice of the Supreme and Universal Mind, who is both the spectator and judge of human actions; it is evident, that the belief of so august a presence, and such awful inspection, must carry a restraint and weight with it proportioned to the strength of that belief, and be an additional motive to the practice of many duties which would not have been performed without it.

It may be observed farther, that "to live under an habitual sense of the Deity and his great administration, is to be conversant with wisdom, order, and beauty, in the highest subjects, and to receive the delightful reflections and benign feelings which these excite, while they irradiate upon him from every scene of nature and providence." How improving must such views be to the mind, in dilating and exalting it above those puny interests and competitions which agitate and enslave the bulk of mankind against each other!—

Motive to Virtue from the Immortality of the Soul, &c.

THE other motive mentioned was the immortality of the soul, with future rewards and punishments. The metaphysical proofs of the soul's immortality, are commonly drawn—from its simple, uncompounded, and indivisible nature; from whence it is concluded, that it cannot be corrupted or extinguished by a dissolution or destruction of parts:—from its having a beginning of motion within itself; whence it is inferred, that it cannot discontinue and lose its motion:—from the different properties of matter and mind; the sluggishness and inactivity of one, and the immense activity of the other; its prodigious flight of thought and imagination; its penetration, memory, foresight, and anticipations of futurity; from whence it is concluded, that a being of so divine a nature cannot be extinguished. But as these metaphysical proofs depend on intricate reasonings concerning the nature, properties,

and distinction of body and mind, with which we are not very well acquainted, they are not obvious to ordinary understandings, and are seldom so convincing, even to those of higher reach, as not to leave some doubts behind them. Therefore, perhaps, it is not so safe to rest the proof of such an important article on what many may call the subtleties of school-learning. Those proofs which are brought from analogy, from the moral constitution and phenomena of the human mind, the moral attributes of God, and the present course of things, and which are therefore called the moral arguments, are the plainest, and generally the most satisfying. We shall select only one or two from the rest.

In tracing the nature and destination of any being, we form the surest judgment from his powers of action, and the scope and limits of these, compared with his state, or with that field in which they are exercised. If this being passes through different states or fields of action, and we find a succession of powers adapted to the different periods of his progress, we conclude that he was destined for those successive states, and reckon his nature progressive. If, besides the immediate set of powers which fit him for action in his present state, we observe another set which appears superfluous if he was to be confined to it, and which point to another or higher one, we naturally conclude, that he is not designed to remain in his present state, but to advance to that for which those supernumerary powers are adapted. Thus we argue, that the insect, which has wings forming or formed, and all the apparatus proper for flight, is not destined always to creep on the ground, or to continue in the torpid state of adhering to a wall, but is designed in its season to take its flight in air. Without this farther destination, the admirable mechanism of wings, and the other apparatus, would be useless and absurd. The same kind of reasoning may be applied to man, while he lives only a sort of vegetative life in the womb. He is furnished even there with a beautiful apparatus of organs, eyes, ears, and other delicate senses, which receive nourishment indeed, but are in a manner folded up, and have no proper exercise or use in their present confinement. Let us suppose some intelligent spectator, who never had any connection with man, nor the least acquaintance with human affairs, to see this odd phenomenon; a creature formed after such a manner, and placed in a situation apparently unsuitable to such various machinery; must he not be strangely puzzled about the use of his complicated structure, and reckon such a profusion of art and admirable workmanship lost on the subject; or reason, by way of anticipation, that a creature, endued with such various, yet unexercised capacities, was destined for a more enlarged sphere of action, in which those latent capacities shall have full play? The vast variety, and yet beautiful symmetry and proportions, of the several parts and organs with which the creature is endued, and their apt cohesion with, and dependence on, the curious receptacle of their life and nourishment, would forbid his concluding the whole to be the birth of chance, or the bungling effort of an unskilful artist, at least would make him demur a while at so harsh a sentence. But if, while he is in this state of uncertainty, we suppose him to see the babe, after a few successful struggles,

struggles, throwing off his fetters, breaking loose from his little dark prison, and emerging into open day; then unfolding his reclusive and dormant powers, breathing in air, gazing at light, admitting colours, sounds, and all the fair variety of nature; immediately his doubts clear up, the propriety and excellency of the workmanship dawn upon him with full lustre, and the whole mystery of the first period is unravelled by the opening of this new scene. Though in this second period the creature lives chiefly a kind of animal life, *i. e.* of sense and appetite; yet by various trials and observations he gains experience, and by the gradual evolution of the powers of imagination he ripens apace for an higher life, for exercising the arts of design and imitation, and of those in which strength or dexterity are more requisite than acuteness or reach of judgment. In the succeeding rational or intellectual period, his understanding, which formerly crept in a lower, mounts into an higher sphere, canvasses the natures, judges of the relations of things, forms schemes, deduces consequences from what is past, and from present as well as past collects future events. By this succession of states, and of correspondent culture, he grows up at length into a moral, social, and a political creature. This is the last period, at which we perceive him to arrive in this his mortal career. Each period is introductory to the next succeeding one; each life is a field of exercise and improvement for the next higher one, the life of the *fœtus* for that of the infant, the life of the infant for that of the child, and all the lower for the highest and best.—But is this the last period of nature's progression? Is this the utmost extent of her plot, where she winds up the drama, and dismisses the actor into eternal oblivion! Or does he appear to be invested with supernumerary powers, which have not full exercise and scope, even in the last scene, and reach not that maturity or perfection of which they are capable; and therefore point to some higher scene, where he is to sustain another and more important character than he has yet sustained? If any such there are, may we not conclude by analogy, or in the same way of anticipation as before, that he is destined for that afterpart, and is to be produced upon a more august and solemn stage, where his sublimer powers shall have proportioned action, and its nature attain its completion?

If we attend to that curiosity, or prodigious thirst of knowledge, which is natural to the mind in every period of its progress; and consider withal the endless round of business and care, and the various hardships to which the bulk of mankind are chained down; it is evident, that in this present state, it is impossible to expect the gratification of an appetite at once so insatiable and so noble. Our senses, the ordinary organs by which knowledge is let into the mind, are always imperfect, and often fallacious; the advantages of assisting, or correcting them, are possessed by few; the difficulties of finding out truth amidst the various and contradictory opinions, interests, and passions of mankind, are many; and the wants of the creature, and of those with whom he is connected, numerous and urgent; so that it may be said of most men, that their intellectual organs are as much shut up and secluded from proper nourishment and exercise in that little circle to which they are confined, as the bodily organs

are in the womb. Nay, those who to an aspiring genius have added all the assistances of art, leisure, and the most liberal education, what narrow prospects can even they take of this unbounded scene of things from that little eminence on which they stand? And how eagerly do they still grasp at new discoveries, without any satisfaction or limit to their ambition?

But should it be said, that man is made for action, and not for speculation, or fruitless searches after knowledge; we ask, For what kind of action? Is it only for bodily exercises; or for moral, political, and religious ones? Of all these he is capable: yet, by the unavoidable circumstances of his lot, he is tied down to the former; and has hardly any leisure to think of the latter; or, if he has, wants the proper instruments of exerting them. The love of virtue, of one's friends and country, the generous sympathy with mankind, and heroic zeal of doing good, which are all so natural to great and good minds, and some traces of which are found in the lowest, are seldom united with proportioned means or opportunities of exercising them; so that the moral spring, the noble energies and impulses of the mind, can hardly find proper scope, even in the most fortunate condition; but are much depressed in some, and almost entirely restrained in the generality, by the numerous clogs of an indigent, sickly, or embarrassed life. Were such mighty powers, such Godlike affections planted in the human breast, to be folded up in the narrow womb of our present existence, never to be produced into a more perfect life, nor to expatiate in the ample career of immortality?

Let it be considered, at the same time, that no possession, no enjoyment within the round of mortal things, is commensurate to the desires, or adequate to the capacities of the mind. The most envied condition has its abatements; the happiest conjuncture of fortune leaves many wishes behind; and after the highest gratifications, the mind is carried forward in pursuit of new ones without end. Add to all, the fond desire of immortality, the secret dread of non-existence, and the high unremitting pulse of the soul beating for perfection, joined to the improbability or the impossibility of attaining it here; and then judge whether this elaborate structure, this magnificent apparatus of inward powers and organs, does not plainly point out an hereafter, and intimate eternity to man? Does nature give the finishing touches to the lesser and ignobler instances of her skill, and raise every other creature to the maturity and perfection of his being; and shall she leave her principal workmanship unfinished? Does she carry the vegetative and animal life in man to their full vigour, and highest destination; and shall she suffer his intellectual, his moral, his divine life to fade away, and be for ever extinguished? Would such abortions in the moral world be congruous to that perfection of wisdom and goodness which upholds and adorns the natural?

We must therefore conclude, from this detail, that the present state, even at its best, is only the womb of man's being, in which the noblest principles of his nature are in a manner fettered or secluded from a correspondent sphere of action; and therefore destined for a future and unbounded state, where they shall emancipate themselves,

and exert the fulcres of their strength. The most accomplished mortal, in this low and dark apartment of nature, is only the rudiments of what he shall be, when he takes his ethereal flight, and puts on immortality. Without a reference to that state, man were a mere abortion, a rude unfinished embryo, a monster in nature. But this being once supposed, he still maintains his rank, of the master-piece of the creation; his latent powers are all suitable to the harmony and progression of nature; his noble aspirations, and the pains of his dissolution, are his efforts towards a second birth, the pangs of his delivery into light, liberty, and perfection; and death his discharge from gaol, his separation from his fellow-prisoners, and introduction into the assembly of those heroic spirits who are gone before him, and of their great eternal Parent. The fetters of his mortal coil being loosened, and his prison-walls broke down, he will be bare and open on every side to the admission of truth and virtue, and their fair attendant happiness; every vital and intellectual spring will evolve itself, with a divine elasticity, in the free air of heaven. He will not then peep at the universe and its glorious Author through a dark grate, or a gross medium, nor receive the reflections of his glory through the strait openings of sensible organs; but will be all eye, all ear, all ethereal and divine feeling.—Let one part, however, of the analogy be attended to; That, as in the womb we receive our original constitution, form, and the essential stamina of our being, which we carry along with us into the light, and which greatly affect the succeeding periods of our life; so our temper and condition in the future life will depend on the conduct we have observed, and the character we have formed in the present life. We are here in miniature what we shall be at full length hereafter. The first rude sketch, or out-lines of reason and virtue, must be drawn at present, to be afterwards enlarged to the stature and beauty of angels.

This, if duly attended to, must prove not only a guard, but an admirable incentive to virtue. For he who faithfully and ardently follows the light of knowledge, and pants after higher improvements in virtue, will be wonderfully animated and inflamed in that pursuit, by a full conviction that the scene does not close with life;—that his struggles arising from the weakness of nature, and the strength of habit, will be turned into triumphs;—that his career in the tracks of wisdom and goodness will be both swifter and smoother;—and those generous ardors with which he glows towards heaven, *i. e.* the perfection and immortality of virtue, will find their adequate object and exercise in a sphere proportionably enlarged, incorruptible, immortal. On the other hand, what an inexpressible damp must it be to the good man, to dread the total extinction of that light and virtue, without which life, nay immortality itself, were not worth a single wish?

Many writers draw their proofs of the immortality of the soul, and of a future state of rewards and punishments, from the unequal distribution of these here. It cannot be dissembled that wicked men often escape the outward punishment due to their crimes, and do not feel the inward in that measure their demerit seems to require, partly from the callousness induced upon their nature by the habits of vice, and partly from the dissipation of their

minds abroad by pleasure or business; and sometimes good men do not reap all the natural and genuine fruits of their virtue, through the many unforeseen or unavoidable calamities in which they are involved. This, no doubt, upon the supposition of an all-wise and good Providence, were an argument, and a strong one too, for a future state, in which those inequalities shall be corrected. But unless we suppose a prepotent good order in the present scene of things, we weaken the proof of the divine administration, and the presumption of better order in any future period of it.

Virtue has present rewards, and vice present punishments, annexed to it; such rewards and punishments as make virtue, in most cases that happen, far more eligible than vice; but, in the infinite variety of human contingencies, it may sometimes fall out, that the inflexible practice of virtue shall deprive a man of considerable advantages to himself, his family, or friends, which he might gain by a well-timed piece of roguery, suppose by betraying his trust, voting against his conscience, selling his country, or any other crime where the security against discovery shall heighten the temptation. Or, it may happen, that a strict adherence to his honour, to his religion, to the cause of liberty and virtue, shall expose him, or his family, to the loss of every thing, nay to poverty, slavery, death itself, or to torments far more intolerable. Now, what shall secure a man's virtue in circumstances of such trial? What shall enforce the obligations of conscience against the allurements of so many interests, the dread of so many and so terrible evils, and the almost unsurmountable aversion of human nature to excessive pain? The conflict is the greater, when the circumstances of the crime are such as easily admit a variety of alleviations from necessity, natural affection, love to one's family, or friends, perhaps in indigence: These will give it even the air of virtue. Add to all, that the crime may be thought to have few bad consequences,—may be easily concealed,—or imagined possible to be retrieved in a good measure by future good conduct. It is obvious to which side most men will lean in such a case, and how much need there is of a balance in the opposite scale, from the consideration of a God, of a providence, and of an immortal state of retribution, to keep the mind firm and incorrupt in those or like instances of singular trial or distress.

But without supposing such peculiar instances, a sense of a Governing Mind, and a persuasion that virtue is not only befriended by him here, but will be crowned by him hereafter with rewards suitable to its nature, vast in themselves, and immortal in their duration, must be not only a mighty support and incentive to the practice of virtue, but a strong barrier against vice. The thoughts of an almighty Judge, and of an impartial future reckoning, are often alarming, inexpressibly so, even to the stoutest offenders. On the other hand, how supporting must it be to the good man, to think that he acts under the eye of his Friend, as well as Judge! How improving, to consider the present state as connected with a future one, and every relation in which he stands as a school of discipline for his affections, every trial as the exercise of some virtue, and the virtuous deeds which result from both as introductory to higher scenes of action and enjoyment! In truth, how transporting

transporting is it to view death as his discharge from the warfare of mortality, and a triumphant entry into a state of freedom, security, and perfection; in which knowledge and wisdom shall break upon him from every quarter; where each faculty shall have its proper object; and his virtue, which was often damped or defeated here, shall be enthroned in undisturbed and eternal empire!

On reviewing this short system of morals, and the motives which support and enforce it, and comparing both with the Christian scheme, what light, and vigour do they borrow from thence! How clearly and fully does Christianity lay open the connections of our nature, both material and immaterial, and future as well as present! What an ample and beautiful detail does it present of the duties we owe to God, to society, and ourselves; promulgated in the most simple, intelligible, and popular manner; divested of every partiality of sect or nation; and adapted to the general fate of mankind! With what bright and alluring examples does it illustrate and recommend the practice of those duties; and with what mighty sanctions does it enforce that practice! How strongly does it

describe the corruptions of our nature; the deviations of our life, from the rule of duty; and the causes of both! How marvellous and benevolent a plan of redemption does it unfold, by which those corruptions may be remedied, and our nature restored from its deviations, to transcendent heights of virtue and piety! Finally, what a fair and comprehensive prospect does it give us of the administration of God, of which it represents the present state only as a small period; and a period of warfare and trial! How solemn and unbounded are the scenes which it opens beyond it; the resurrection of the dead; the general judgment; the equal distribution of rewards and punishments to the good and the bad; and the full completion of divine wisdom and goodness in the final establishment of order, perfection, and happiness!—How glorious then is that scheme of religion, and how worthy of affection as well as of admiration, which, by making such discoveries, and affording such assistances, has disclosed the un fading fruits and triumphs of virtue, and secured its interests beyond the power of time and chance!

M O R

MORAL SENSE, that whereby we perceive what is good, virtuous, and beautiful in actions, manners, and characters. See **MORALS**.

MORALITY. See **MORAL PHILOSOPHY**.

MORASS, a low, moist land, which receives the waters from the higher grounds without having any descent to carry them off.

MORAVIA, a marquisate, or province in Bohemia, bounded by Silesia on the north-east, by Hungary and Austria on the south, and by Bohemia on the north-west.

MORAVIANS, a sect of Protestants, who have been settled for a considerable time past at Hernhuth in Germany, and have of late years spread themselves over most of our American colonies, as well as in several parts of England, where they are permitted to settle by a late act of parliament. They have a kind of church-government peculiar to themselves, and are commonly known by the name of *Unitas Fratrum*, or *The Brethren*. They profess the utmost veneration for our blessed Saviour, whom they consider as their immediate Head and Director; enjoin the most implicit obedience to the rulers of their church; and are said to practise much brotherly love amongst one another.

MORBID, among physicians, signifies diseased or corrupt; a term applied either to an unfound constitution, or to those parts or humours that are infected by a disease.

MORDELLA, in zoology, a genus of the coleoptera class of insects. The antennæ are thread-shaped, and serrated; the head is deflexed under the neck; the pappi are clavated, compressed, and obliquely blunted; and the elytra are bent backwards near the apex. There are six species, all natives of different parts of Europe.

MOREA, the ancient Peloponnesus, is a province of European Turkey, and is a peninsula about one hun-

M O R

dred and eighty miles long, and one hundred and thirty broad, bounded by the gulphs of Lepanto and Engia on the north; by the Egean sea, or Archipelago, on the east; and by the Mediterranean on the south and west.

MORESKE, or **MORISCO**, is a kind of painting, carving, &c. done after the manner of the Moors; consisting of several grotesque pieces and compartments, promiscuously mingled, not containing any perfect figure of a man, or other animal; but a wild resemblance of birds, beasts, trees, &c.

MORGAY, in ichthyology. See **SQUALUS**.

MORINA, in botany, a genus of the diandria monogynia class. The corolla is unequal; the calix of the fruit consists of one dentated leaf; the calix of the flower is bifid; and there is but one seed under the flower-calix. There is but one species, a native of Persia.

MORINDA, in botany, a genus of the pentandria monogynia class. The flowers are aggregate and monopetalous; the stigma is bifid; and the drupe is aggregate. There are three species, none of them natives of Britain.

MORINELLUS, in ornithology. See **CHARADRIUS**.

MORISONA, a genus of the polyandria monogynia class. The corolla consists of four petals, and the calix of two segments; the berry is hard, and contains one seed. There is but one species, a native of America.

MORLAIX, a port-town of France, in the province of Britany: W. long. 4°, N. lat. 48° 37'.

MORMYLUS, in ichthyology. See **SPARUS**.

MORNING, the beginning of the day, the first appearance of light, or the time from midnight till noon.

MOROCCO, the capital of the kingdom of the same name in Africa: W. long. 9°, N. lat. 32°.

MOROCHTHUS, in natural history, an indurated clay, called by us French chalk; serving taylois and others

to mark with. The ancients esteemed it as an astrigent, prescribing it in the colic, hæmorrhages and other fluxes.

MORPETH, a borough-town of Northumberland, fourteen miles north of Newcastle, which sends two members to parliament.

MORTALITY, or *Bills of MORTALITY*, properly denote weekly lists of the persons who die in any place. See *ANNUITIES*.

Brief of MORTANCESTRY, in Scots law; anciently the ground of an action at the instance of an heir, in the special case where he had been excluded from the possession of his ancestor's estate by the superior or other person pretending right.

MORTAR, a preparation of lime and sand mixed up with water, which serves as a cement, and is used by masons and bricklayers in building of walls of stone and brick.

MORTAR-PIECE. See *GUNNERY*.

MORTGAGE, in law, a pledge or pawn of lands, tenements, &c. for money borrowed; so called, because if the money is not paid at the day, the land dies to the debtor, and is forfeited to the creditor.

MORTIER, an ensign of dignity, borne by the chancellor and grand presidents of the parliament of France. That borne by the chancellor, is a piece of cloth of gold, edged and turned up with ermine; and that of the first president is a piece of black velvet edged with a double row of gold lace, while that of the other presidents is only edged with a single row. This they formerly carried on their heads, as they do still in grand ceremonies, such as the entry of the king; but, ordinarily, they carry them in the hand.

MORTISE, or *MORTOISE*, in carpentry, &c. a kind of joint, whereby a hole of a certain depth is made in a piece of timber, which is to receive another piece called a tenon.

MORTMAIN, in law, is the alienation of lands or tenements to any religious house, corporation, or fraternity, and their successors.

MORTUARY, in the ecclesiastical law, is a gift left by a man at his death to his parish church, in recompence of personal tithes omitted to be paid in his lifetime: or it is that beast, or other cattle, which, after the death of the owner, by the custom of the place, is due to the parson or vicar, in lieu of tithes or offerings forgot, or not well and truly paid by him that is dead.

MORUS, in botany, a genus of the monœcia tetrandria class. The calyx of the male has four segments; it has no corolla: The calyx of the female consists of four leaves; it has no corolla; the styli are two, and the berry contains one seed. There are seven species, none of them natives of Britain.

MOSAIC, or *MOSAIC-WORK*, an assemblage of little pieces of glass, marble, precious stones, &c. of various colours, cut square, and cemented on a ground of stucco, in such a manner as to imitate the colours and degradations of painting.

Method of performing MOSAIC-WORK of glass is this:

They provide little pieces of glass, of as many different colours and sizes as possible.

Now, in order to apply these several pieces, and out of them to form a picture, they in the first place procure a cartoon or design to be drawn; this is transferred to the ground or plaster by calking, as in painting in fresco. See *Fresco*.

As this plaster is to be laid thick on the wall, and therefore will continue fresh and soft a considerable time, so that there may be enough prepared at once, to serve for as much work as will take up three or four days.

This plaster is composed of lime, made of hard stone, with brick dust very fine, gum tragacanth, and whites of eggs: when this plaster has been thus prepared and laid on the wall, and made the design of what is to be represented, they take out the little pieces of glass with a pair of piers, and range them one after another, still keeping strictly to the light, shadow, different taints and colours represented in the design before; pressing or flattening them down with a ruler, which serves both to sink them within the ground, and to render the surface even.

Thus in a long time, and with a great deal of labour, they finish the work, which is still the more beautiful, as the pieces of glass are more uniform, and ranged at an even height.

Some of these pieces of mosaic-work are performed with that exactness, that they appear as smooth as a table of marble, and as finished and masterly as a painting in fresco; with this advantage, that they have a fine lustre, and will last ages.

The finest works of this kind that have remained till our time, and those by whom the moderns have retrieved the art, which was in a manner lost, are those in the church of St Agnes, formerly the temple of Bacchus at Rome; and some at Pifa, Florence, and other cities of Italy. The most esteemed among the works of the moderns are those of Joseph Pine, and the chevalier Lanfranc in the church of St Peter at Rome: there are also very good ones at Venice.

Method of performing MOSAIC-WORK of marble and precious stones is this: The ground of mosaic-works, wholly marble, is usually a massive marble, either white or black. On this ground the design is cut with a chisel, after it has been first calqued. After it has been cut of a considerable depth, *i. e.* an inch or more, the cavities are filled up with marble of a proper colour, first fashioned according to the design, and reduced to the thickness of the indentures with various instruments. To make the pieces thus inserted into the indentures cleave fast, whose several colours are to imitate those of the design, they use a stucco, composed of lime and marble-dust; or a kind of mastic, which is prepared by each workman, after a different manner peculiar to himself.

The figures being marked out, the painter or sculptor himself draws with a pencil the colours of the figures, not determined by the ground, and in the same manner makes strokes or hatchings in the place, with

where shadows are to be : and after he has engraven with the chisel all the strokes thus drawn, he fills them up with a black mastic, composed partly of burgundy-pitch poured on hot; taking off afterwards what is superfluous with a piece of soft stone or brick, which, together with water and beaten cement, takes away the mastic, polishes the marble, and renders the whole so even that one would imagine it only consisted of one piece.

This is the kind of mosaic-work that is seen in the pompous church of the invalids at Paris, and the fine chapel at Versailles, with which some entire apartments of that palace are incrustated.

As for mosaic-work of precious stones, other and finer instruments are required than those used in marble; as drills, wheels, &c. used by lapidaries and engravers on stone. As none but the richest marbles and stones enter this work, to make them go the farther, they are sawn into the thinnest leaves imaginable, scarce exceeding half a line in thickness; the block to be sawn is fastened firmly with cords on the bench, and only raised a little on a piece of wood, one or two inches high. Two iron pins, which are on one side the block, and which serve to fasten it, are put into a vice contrived for the purpose; and with a kind of saw or bow, made of fine brass-wire, bent on a piece of spongy wood, together with emery steeped in water, the leaf is gradually fashioned by following the stroke of the design, made on paper, and glued on the piece. When there are pieces enough fastened to form an entire flower, or some other part of the design, they are applied to the ground.

The ground which supports this mosaic-work is usually of free-stone. The matter with which the stones are joined together, is a mastic, or kind of stucco, laid very thin on the leaves as they are fashioned; and this being done, the leaves are applied with pliers.

If any contour, or side of a leaf, be not either squared or rounded sufficiently, so as to fit the place exactly, into which it is to be inserted, when it is too large, it is to be brought down with a brass file or rasp; and if it be too little, it is managed with a drill and other instruments used by lapidaries.

Mosaic-work of marble is used in large works, as in pavements of churches, basilics, and palaces; and in the incrustation and vanecing of the walls of the same edifices.

As for that of precious stones, it is only used in small works, as ornaments for altar-pieces, tables for rich cabinets, precious stones being so very dear.

Manner of performing MOSAIC WORK of gypsum. Of this stone calcined in a kiln, and beaten in a mortar, and sifted, the French workmen make a sort of artificial marbles, imitating precious stones; and of these they compose a kind of mosaic-work, which does not come far short either of the durability or the vivacity of the natural stones; and which besides has this advantage, that it admits of continued pieces or paintings of entire compartments without any visible joining.

Some make the ground of plaster of Paris, others of

free stone. If it be of plaster of Paris, they spread it in a wooden frame, of the length and breadth of the work intended, and in thickness about an inch and a half. This frame is so contrived, that the tenons being only joined to the mortises by single pins, they may be taken asunder, and the frame be dismounted, when the plaster is dry. The frame is covered on one side with a strong linen cloth, nailed all round, which being placed horizontally with the linen at the bottom, is filled with plaster passed through a wide sieve. When the plaster is half dry, the frame is set up perpendicularly, and left till it is quite dry; then it is taken out, by taking the frame to pieces.

In this mosaic, the ground is the most important part. Now in order to the preparation of this sifted gypsum, which is to be applied on this ground, it is dissolved and boiled in the best English glue, and mixed with the colour that it is to be of; then the whole is worked up together into the usual consistence of plaster, and then is taken and spread on the ground five or six inches thick. If the work be such, as that mouldings are required, they are formed with gougues and other instruments.

It is on this plaster, thus coloured like marble or precious stone, and which is to serve as a ground to a work, either of lapis, agate, alabaster, or the like, that the design to be represented is drawn; having been first pounced or calqued. To hollow or impress the design, they use the same instruments that sculptors do; the ground whereon they are to work not being much less hard than the marble itself. The cavities being thus made in the ground, are filled with the same gypsum boiled in glue, only differently coloured, and thus are the different colours of the original represented. In order that the necessary colours and tints may be ready at hand, the quantities of the gypsum are tempered with the several colours in pots.

After the design has been thus filled and rendered visible, by half-polishing it with brick and soft stone, they go over it again, cutting such plates as are either to be weaker or more shadowed, and filling them with gypsum; which work they repeat, till all the colours being added one after the other, represent the original to the life.

When the work is finished, they scour it with soft stone, sand, and water; after that, with a pumice-stone; and in the last place polish it with a wooden mullet and emery. Then, lastly, they give it a lustre, by smearing it over with oil, and rubbing it a long time with the palm of the hand, which gives it a lustre no ways inferior to that of natural marble.

MOSAMBIQUE, the capital of a province of the same name in Zanguebar, in Africa, situated on an island at the mouth of the river Mosambique : E. lon. 40°. S. lat. 15°.

MOSCHUS, a genus of quadrupeds of the order of pecora, having no horns; the canine teeth of the upper jaw are exerted. There are three species, viz. 1. The moschiferus, or musk animal, has a bag or pellicle near the navel, in which the perfume called musk is contained.

This creature, when full grown, is three feet in length, from the tip of the nose to the rump; the head is oblong, and the anterior part much like the greyhound; the ears are large and erect, they resemble those of the rabbit, and are equal in length to the diameter of the forehead; the tail is not more than two inches in length, and the creature always carries it erect; the body is tolerably fleshy, and rounded; the legs about a foot in length, and very robust; the feet deeply divided, each into two claws in the anterior part, and as many heels behind. The fur on the head and that on the legs is about half an inch long, that on the belly is an inch and a half, and that which grows on the back three inches; these hairs are thicker than in any other known animal, and are variegated, from the base to the extremity, with distinct spaces of brown and white. The vessel or bag in which the perfume called musk is contained, is three inches long and two broad, and hangs under the belly, protuberant near three quarters of an inch beyond the surface. It is a native of Tartary.—2. The grimmia has a protuberant hump upon its head, and is found in Africa. 3. The pygmæus has feet narrower than a man's finger. It is found in Asia and Guinea.

MOSCOW, the capital of the province of the same name in Muscovy, situated on the river Moscowa, 260 miles south-east of Petersburg: E. long. 38°, N. lat. 55° 45'.

MOSCOWA, a river which rises in the west part of the province of Moscow, and falls into the river Ocka at Kolomna.

MOSSELLE, a river of Germany, which rises in the mountains of Vauge, in Lorrain, and, running thro' that duchy and the electorate of Triers, falls into the Rhine at Coblenz.

MOSKITO, a country of North America, situated between 85° and 88° of west longitude, and between 13° and 15° of north latitude; having the north sea on the north and east, Nicaragua on the south, and Honduras on the west.

MOSBURG, or **MOSPURG**, a town of Germany, in the circle of Bavaria, situated at the confluence of the rivers Isar and Amberg, thirty miles north-east of Munich.

MOSQUE, a temple, or place of religious worship, among the Mahometans.

All mosques are square buildings, generally built with stone. Before the chief gate there is a square court, paved with white marble; and low galleries round it, whose roof is supported by marble pillars. In these galleries the Turks wash themselves before they go into the mosque. In each mosque there is a great number of lamps; and between these hang many crystal rings, ostriches eggs, and other curiosities, which when the lamps are lighted make a fine shew. As it is not lawful to enter the mosques with shoes or stockings on, the pavements are covered with pieces of stuff sewed together, each being wide enough to hold a row of men kneeling, sitting, or prostrate. The women are not allowed to enter the mosque, but stay in the porches without. About every mosque

there are six high towers, called minarets, each of which has three little open galleries, one above another: these towers, as well as the mosques, are covered with lead, and adorned with gilding and other ornaments; and from thence, instead of a bell, the people are called to prayers by certain officers appointed for that purpose. Most of the mosques have a kind of hospital belonging to them, in which travellers, of what religion soever, are entertained during three days. Each mosque has also a place called Tarbe, which is the burying place of its founders; within which is a tomb six or seven feet long, covered with green velvet or satin; at the ends of which are two tapers, and round it several seats for those who read the koran and pray for the souls of the deceased.

MOSS, in botany. See **MUSCUS**.

Moss is also a name given to boggy grounds in many parts of the kingdom. These consist of a turfy surface, below which is a black, moist, spongy earth, which being dug up with spades somewhat in the form of bricks, and dried, is what they call peats, used as fuel in several parts; and the upper scurf, being cut and dried, makes turfs, another coarser sort of fuel.

MOSTRA, in the Italian music, a mark at the end of a line or space, to shew that the first note of the next line is in that place: and if this note be accompanied with a sharp or flat, it is proper to place these characters along with the mostra.

MOTACILLA, in ornithology, a genus of birds, of the order of the passeræ, distinguished by a straight beak, of a subulated figure, and a lacerated tongue. There are 49 species belonging to this genus, most of which feed upon insects, and migrate from the north to the southern countries in order to procure subsistence in winter.

MOTE, in law-books, signifies court or convention; as a ward-mote, burgh-mote, swain-mote, &c.

MOTH, in zoology. See **PHALÆNA**.

MOTHER, a term of relation, denoting a woman who hath born a child.

MOTION, is defined to be the continued and successive change of place. See **MECHANICS**.

MOTTO, in armoury, a short sentence or phrase carried in a scroll, generally under, but sometimes over the arms; sometimes alluding to the bearing, sometimes to the name of the bearer, and sometimes containing whatever pleases the fancy of the deviser.

MOVEABLE, in general, denotes any thing capable of being moved.

MOVEABLE Subject, in Scots law, any thing that moves itself, or can be moved; in contradistinction to immoveable or heretable subjects, as lands, houses, &c. See **LAW**, Tit. ix. 2.

MOVEMENT, in mechanics, a machine that is moved by clock work. See **WATCH**.

Perpetual MOVEMENT. Some have attempted to find a perpetual movement, but without success; and there is reason to think, from the principles of mechanics, that such a movement is impossible: for though in many cases of bodies acting upon one another, there is a

gain of absolute motion; yet the gain is always equal in opposite directions, so that the quantity of direct motion is never increased.

To make a perpetual movement it appears necessary, that a certain system of bodies, of a determined number and quantity, should move in a certain space for ever, and in a certain way and manner: and for this there must be a series of actions returning in a circle, otherwise the movement will not be perpetual; so that any action by which the absolute quantity of force is increased, of which there are several sorts, must have its corresponding counter-action, by which the gain of force is destroyed, and the quantity of force restored to its first state.

Thus, by these actions, there will never be any gain of direct force, to overcome the friction and the resistance of the medium; so that every motion being diminished by these resistances, they must at length languish and cease.

MOULD, or **MOLD**, in the mechanic arts, &c. a cavity cut with a design to give its form or impression to some softer matter applied therein, of great use in sculpture, foundery, &c.

MOULD, in agriculture, a loose kind of earth, every where obvious on the surface of the ground, called also natural or mother earth; by some also loam.

MOULDINESS, a term applied to bodies which corrupt in the air, from some hidden principle of humidity therein; and whose corruption shews itself by a certain white down, or lanugo, on their surface, which, viewed through a microscope, appears like a kind of meadow, out of which arise herbs and flowers, some only in the bud, others full blown, and others decayed, each having its root, stalk, and other parts.

MOULDING, any thing cast in a mould, or that seems to have been so, though in reality it were cut with a chisel, or the ax.

MOULDINGS, in architecture, projectures beyond the naked wall, column, wainscot, &c. the assemblage of which forms corniches, door-cases, and other decorations of architecture. See ARCHITECTURE.

MOULINET, is used, in mechanics, to signify a roller, which being crossed with two levers, is usually applied to cranes, capstans, and other sorts of engines of the like nature, to draw ropes, and heave up stones, &c.

MOULINET is also a kind of turnstile, or wooden cross, which turns horizontally upon a stake fixed in the ground; usually placed in passages to keep out horses, and to oblige passengers to go and come one by one. These moulinets are often set near the outworks of fortified places at the sides of the barriers, through which people pass on foot.

FOUND, a term used for a bank or rampart, or other fence, particularly that of earth.

FOUND, in heraldry, a ball or globe with a cross upon it, such as our kings are usually drawn with, holding it in their left hand, as they do the sceptre in the right.

FOUNT, an elevation of earth, called also mountain. See MOUNTAIN.

FOUNT ST MICHAEL, a borough town of Cornwall,

situated on a bay of the English channel, called Mount-bay, eighteen miles west of Falmouth.

It sends two members to parliament.

FOUNT-SORREL, a market town of Leicestershire, seven miles north of Leicester.

FOUNT OF PIETY, certain funds or establishments in Italy, where money is lent out, on some small security. We had also founts of piety in England, raised by contribution for the benefit of people ruined by the extortions of the Jews.

FOUNTAIN, a part of the earth, rising to a considerable height above the level of the surface thereof.

FOUNT, in zoology. See MUR.

FOUNT-EAR, in botany. See HIERACHIUM.

FOUNT-TAIL. See MYOSURUS.

FOUNT-MOUSE. See SOREX.

FOUNT-MOUSE. See APHRODITA.

FOUNTSEL, or **MOSEL**, a city of Asiatic Turkey, in the province of Diarbec, or Mesopotamia, situated on the river Tigris, opposite the place where Nineveh stood; E. long. 43°, and N. lat. 36°.

FOUNT, in anatomy. See ANATOMY, p. 299.

FOUNT is used in the courts of princes, for what relates to their eating and drinking: Hence officers of the mouth, yeomen of the mouth.

FOUNTSLAW, the capital of the palatinate of Mscyslaw in Poland, situated on the frontiers of Muscovy: E. long. 31° 30', and N. lat. 54° 34'.

FOUNTILAGE, in pharmacy, is in general any viscid and glutinous liquor.

FOUNTILAGE also imports the liquor which principally serves to moisten the ligaments and cartilages of the articulations; and is supplied by the mucilaginous glands.

FOUNT, in botany, a genus of the cryptogamia fungi class. It consists of small bladders, containing numerous seeds. There are twelve species, seven of them natives of Britain.

FOUNT CORDIS, in anatomy, the lower or pointed end of the heart.

FOUNT, a mucilaginous liquor separated by the mucous glands and the nostrils. See ANATOMY.

FOUNT, a town of Germany, in the circle of Austria, and duchy of Stiria, situated on the river Muer, twenty-five miles north west of Graz.

FOUNTLE, in Chemistry. See CHEMISTRY, p. 109.

FOUNT, the chief of the ecclesiastical order, or primate of the muselman religion. The authority of the musti is very great in the Ottoman empire; for even the sultan himself, if he would preserve any appearance of religion, cannot, without hearing his opinion, put any person to death, or so much as inflict any corporal punishment. In all actions, especially criminal ones, his opinion is required, by giving him a writing, in which the case is stated, under feigned names; which he subscribes with the words, *He shall, or shall not be punished*. Such outward honour is paid to the musti, that the grand seignior himself rises up to him, and advances seven steps to meet him, when he comes into his presence. He alone has the honour of kissing the sultan's left shoulder, whilst the prime vizier kisses only

only the hem of his garment. When the grand feignior addresses any writing to the mufti, he gives him the following titles, "To the efad, the wifeft of the wife, instructed in all knowledge, the moft-excellent of excellents, abftaining from things unlawful, the fpring of virtue and true fcience, heir of the prophetic doctrines, refolver of the problems of faith, revealer of the orthodox articles, key of the treafures of truth, the light to the doubtful allegories, ftrengthened with the grace of the fupreme legiflator of mankind, may the moft high God perpetuate thy virtues." The election of the mufti is folely in the grand feignior, who prefents him with a veft of rich fables, &c. If he is convicted of treafon, or any great crime, he is put into a mortar, kept for that purpofe in the Seven Towers at Conftantinople, and pounded to death.

MUGGLETONIANS, a religious feft which arofe in England, about the year 1657; fo denominated from their leader Lodowick Muggleton, a journeyman taylor, who, with his affociate Reeves, fet up for great prophets, pretending, as it is faid, to have an abfolute power of faving and damning whom they pleafed; and giving out that they were the two laft witneffes of God that fhould appear before the end of the world.

MUGIL, in ichthyology, a genus of fifhes belonging to the order of abdominales. The lips are membranaceous, the inferior one being carinated inwards; they have no teeth; the branchioftege membrane has feven crooked rays; the opercula are fmooth and round; and the body is of a whitifh colour. There are two fpecies diftinguifhed by the number of rays in the back-fin.

MUG-WORT, in botany. See **ARTEMISIA**.

MUID, a large meafure, in ufe among the French, for things dry. The muid is no real vefel ufed as a meafure, but an eftimation of feveral other meafures, as the feptier, mine, minot, bufhel, &c.

MUID, is alfo one of the nine casks, or regular veffels ufed in France, to put wine and other liquors in. The muid of wine is divided into two demi-muids, four quarter-muids, and eight half-quarter-muids, containing 36 feptiers.

MULL, one of the weftern iflands of Scotland, being part of the fhire of Argyle, and lying to the weftward of it: this ifland is twenty-four miles long, and in fome places as many broad.

MULL of Cantire, the fouth cape or promontory of the county of Cantire or Mul, in the frith of Clyde, on the weft of Scotland.

MULL of Galloway, the fouth cape or promontory of all Scotland, in the county of Galloway, on the Irifh fea.

MULATTO, a name given in the Indies to thofe who are begotten by a negro man on an Indian woman, or an Indian man on a negro woman.

MULBERRY, in botany. See **MORUS**.

MULCT, a fine of money laid upon a man who has committed fome fault or mifdemeanor.

MULDAW, a river of Bohemia, that arifes on the confines of Austria, and running north, through Bohemia, unites with the Elbe at Melnick.

MULE, in zoology, a mongrel kind of quadruped, usu-

ally generated between an afs and a mare, and fometimes between a horfe and a fheafs.

MULLERAS, a town of Germany, in the circle of Upper Saxony, and marquifate of Brandenburg, fituated thirty-eight miles fouth-eaft of Berlin.

MULLETT, in ichthyology. See **MUGIL**.

MULLET, or **MOLLET**, in heraldry, a bearing in form of a flat, or rather of the rowel of a fpur, which it originally reprefented.

The mullet has but five points; when there are fix it is called a ftar; though others make this difference, that the mullet is, or ought to be, always pierced, which a ftar is not. See plate CVI. The mullet is ufually the difference or diftinguifhing mark for the fourth fon, or third brother, or houfe; though it is often borne alone, as coat armour.

MULSUM, a liquor made of wine and honey, or even of wine and water.

MULTAN, or **MOVTAN**, a city of hither India in Affia, capital of the province of Multan, fituated on the river Indus. E. long. 72° 15', N. lat. 30°.

MULTIPLE, in arithmetic, a number which comprehends fome other feveral times, thus 6 is a multiple of 2, and 12 is a multiple of 6, 4, and 3, comprehending the firft twice, the fecond thrice, &c.

Action of MULTIPLEPOINDING, in Scots law. See **LAW**, Tit. xxx. 24.

MULTIPLICAND, in arithmetic. See **ARITHMETIC**, p. 371.

MULTIPLICATION, in general, the act of increafing the number of any thing.

Multiplication in arithmetic, is a rule by which any given number may be fpeedily increafed, according to any propofed number of times. See **ARITHMETIC**, p. 371.

MULTIPLICATION, in algebra. See **ALGEBRA**, p. 81.

MULTIPLICATOR, or **MULTIPLIER**, in arithmetic. See **ARITHMETIC**, p. 371.

MULTIPLYING GLASS, in optics, one wherein objects appear increafed in number. See **OPTICS**.

MULTURE, in Scots law, the quantity of grain paid to the proprietor or tackfman of a mill for grinding. See **LAW**, Tit. xvi. 12.

MULVIA, a river of Barbary, in Africa, which rifes in the mountains of Atlas, and divides the empire of Morocco from the kingdom of Algiers, and then falls into the Mediterranean, weft of Marfalquiver.

MUM, a kind of malt-liquor, much drank in Germany; and chiefly brought from Brunfwick, which is the place of moft note for making it. The procefs of brewing mum, as recorded in the town-houfe of that city, is as follows: Take fixty-three gallons of water that has been boiled till one third part is confumed, and brew it with feven bufhels of wheaten malt, one bufhel of oat-meal, and one bufhel of ground beans; when it is tunned, the hoghead muft not be filled too full at firft: as foon as it begins to work, put into it three pounds of the inner rind of fir, one pound of the tops of fir and beech, three handfals of cardus benedictus, a handfal or two of the flower of rofa folis; add barnet, betony,

betony, marjoram, avens, penny royal, and wild thyme, of each a handful and a half; of elder flowers, two handfuls or more; seeds of cardamum bruised, thirty ounces; barberies bruised, one ounce; when the liquor has worked a while, put the herbs and seeds into the vessel; and, after they are added, let it work over as little as possible; then fill it up: lastly, when it is stopped, put into the hoghead ten new-laid eggs unbroken; stop it up close, and drink it at two years end. Our English brewers, instead of the inner rind of fir, use cardamum, ginger, and saffras; and also add elecampane, madder, and red sanders. Mum, on being imported, pays for every barrel 1 l. 5 s.

MUMMY, a body embalmed or dried, in the manner used by the ancient Egyptians; or the composition with which it is embalmed. There are two kinds of bodies denominated mummies: the first are only carcases dried by the heat of the sun, and by that means kept from putrefaction: These are frequently found in the sands of Lybia. Some imagine, that these are the bodies of deceased people buried there on purpose to keep them entire without embalming; others think they are the carcases of travellers, who have been overwhelmed by the clouds of sand raised by the hurricanes frequent in those deserts. The second kind of mummies are bodies taken out of the catacombs near Cairo, in which the Egyptians deposited their dead after embalming.

We have two different substances preserved for medicinal use under the name of mummy, though both in some degree of the same origin. The one is the dried and preserved flesh of human bodies, embalmed with myrrh and spices; the other is the liquor running from such mummies, when newly prepared, or when affected by great heat or damps. The latter is sometimes in a liquid, sometimes of a solid form, as it is preserved in vials well stopped, or suffered to dry and harden in the air. The first kind of mummy is brought to us in large pieces, of a lax and friable texture, light and spongy, of a blackish brown colour, and often damp and clammy on the surface: it is of a strong but disagreeable smell. The second kind of mummy, in its liquid state, is a thick, opaque, and viscous fluid, of a blackish colour, but not disagreeable smell. In its indurated state, it is a dry solid substance, of a fine shining black colour, and close texture, easily broken, and of a good smell; very inflammable, and yielding a scent of myrrh and aromatic ingredients while burning. This, if we cannot be content without medicines from our own bodies, ought to be the mummy used in the shops; but it is very scarce and dear; while the other is so cheap, that it will always be most in use.

All these kinds of mummy are brought from Egypt. But we need not to imagine, that any body breaks up the real Egyptian mummies, to sell them in pieces to the druggists, as they may make a much better market of them in Europe whole, when they can contrive to get them. What our druggists are supplied with, is the flesh of executed criminals, or of any other bodies the Jews can get, who fill them with the common bitumen so plentiful in that part of the world; and adding

a little aloes, and two or three other cheap ingredients, send them to be baked in an oven, till the juices are exhaled, and the embalming matter has penetrated so thoroughly that the flesh will keep and bear transporting into Europe. Mummy has been esteemed resolvent and balsamic: but whatever virtues have been attributed to it, seem to be such as depend more upon the ingredients used in preparing the flesh, than in the flesh itself; and it would surely be better to give those ingredients without so shocking an addition.

MUMMY, among gardeners, a kind of wax used in grafting and planting the roots of trees, made in the following manner: Take one pound of black pitch, and a quarter of a pound of turpentine; put them together into an earthen pot, and set them on fire in the open air, holding something in your hand to cover and quench the mixture in time, which is to be alternately lighted and quenched till all the nitrous and volatile parts be evaporated. To this a little common wax is to be added; and the composition is then to be set by for use.

MUNGATS, or **МУНКАТС**, a town of upper Hungary: E. long. 22°, N. lat. 48° 30'.

MUNICH, a large and elegant city, the capital of the electorate and duchy of Bavaria situated on the river Isar: E. long. 11° 32', N. lat. 48° 5'.

MUNICIPAL, in the Roman civil law, an epithet which signifies invested with the rights and privileges of Roman citizens. Thus the municipal cities were those whose inhabitants were capable of enjoying civil offices in the city of Rome: These cities, however, according to Mariana, had fewer privileges than the colonies: They had no suffrages or votes at Rome; but were left to be governed by their own laws and magistrates. Some few municipal cities, however, obtained the liberty of votes.

Municipal, among us, is applied to the laws that obtain in any particular city or province. And those are called municipal officers who are elected to defend the interest of cities, to maintain their rights and privileges, and to preserve order and harmony among the citizens; such as mayors, sheriffs, consuls, &c.

MUNITION, the provisions with which a place is furnished in order for defence; or that which follows a camp for its subsistence.

MUNSTER, the capital of the bishoprick of the same name, and of the circle of Westphalia, situated on the river Aa: E. long. 7° 10', N. lat. 52°.

MUNSTER, is also a town of Germany, in the Landgraviate of Alsatia, subject to France: E. long. 7° 5', N. lat. 48° 8'.

MUNSTER MEINFELT, a town of Germany, in the circle of the lower Rhine and electorate of Triers: E. long. 7°, N. lat. 50° 15'.

MUNSTERBERG, the capital of the duchy of the same name in Silesia: E. long. 16°, N. lat. 50° 35'.

MUNTINGIA, in botany, a genus of the polyandria monogynia class. The calix consists of five segments, and the corolla of five petals; and the berry has one cell containing many seeds. There is but one species, a native of America.

MURÆNA,

MURÆNA, or **EEL**, in ichthyology, a genus of fishes belonging to the order of apodes. The head is smooth; there are ten rays in the membrane of the gills; the eyes are covered with a common skin; and the body is cylindrical, and slimy. There are seven species, distinguished by their fins, tail, &c.

MURCIA, the capital of the province of the same name in Spain: W. long. 1° 12', N. lat. 38° 6'.

MURDER, or **MURTHUR**, in law, is the wilful and felonious killing a person from premeditated malice; provided the party wounded, or otherwise hurt, die within a year and a day after the fact was committed. See **LAW**, Tit. xxxiii.

MURDERERS, or **MURDERING-PIECES**, in a ship, are small pieces of ordnance, either of brass or iron, which have chambers put in at their breeches. They are used at the bulk-heads of the fore cattle, half-deck, or steerage, in order to clear the deck, on the ship's being boarded by an enemy.

MURENGERS, two officers of great antiquity in the city of Chester, annually chosen out of the aldermen, to see that the walls are kept in repair, and to receive a certain toll and custom for the maintenance thereof.

MUREX, in zoology, a genus of insects belonging to the order of vermes testacea. This animal is of the snail kind; the shell consists of one spiral valve, rough with membranaceous furrows; and the aperture terminates in an entire canal either straight or somewhat ascending. There are 60 species, particularly distinguished by peculiarities in their shells, &c.

MURIA, ALIMENTARY SALT. See **SALT**.

MURO, a town of Italy, in the kingdom of Naples, sixty miles south-east of the city of Naples.

MURRAIN, or **GARGLE**, a contagious disease among cattle.

The symptoms of this disease are a hanging down and swelling of the head, abundance of gum in the eyes, rattling in the throat, a short breath, palpitation at the heart, staggering, a hot breath, and a shining tongue.

In order to prevent this disease, the cattle should stand cool in summer, have plenty of good water; all carrion should be speedily buried; and as the feeding of cattle in wet places, on rotten grass and hay, often occasions this disease, dry and sweet fodder should be given them.

MURRAY, a county of Scotland, bounded by the German Sea, on the north; by Banff, on the east; by Mar and Badenoch, on the south; and by Inverness, on the west.

MURREY, in heraldry, a kind of purple colour. See **SANGUINE**.

MUS, in zoology, a genus of quadrupeds, belonging to the order of glires; the generic character of which is, that the fore-teeth of the lower jaws are subulated. There are 21 species. 1. The porcellus, or guiney-pig, has no tail; there are four toes on the fore-feet, and three on the hind ones. This animal makes a grunting noise, is very restless, and stamps with its hind-feet when teased. It loves heat, and feeds upon various vegetables. The female has two dugs. The colour is very various. It is a native of Brazil. 2. The agati has a short tail, four toes on the fore-
